In the clinics, dental students gain experience in the correction and control of dental diseases and disorders. Here, too, the community finds an additional source of dental services, some of which are frequently unobtainable outside the dental school.

Patient Movement in the Clinics Figure 9 illustrates patient movement through the clinics. The new patient first reports to the information desk located in the lobby or main waiting room of the clinic area. He then proceeds to the regis-

tration desk, where a case record is opened for him. At the appointment desk, his next stop, he is scheduled for an oral examination.

The patient then undergoes, either on the initial visit or a subsequent one, a screening examination. This procedure enables the school to select patients with varied dental problems.

Following the screening examination, the patient goes to the radiology clinic for full-mouth roentgenograms and then to the diagnostic clinic for a thorough oral examination, performed by a dental student working under the direction of an instructor. When the examination is completed, the patient returns to the appointment desk where he is referred for subsequent visits either to the general dental clinic or to one of the special clinics. On later visits, the patient reports directly to the waiting room of the clinic where he will receive treatment.

Reception and Screening Area The reception area in the main waiting room is the control center of the clinics, coordinating the flow of patients and records to clinics in the treatment area. In addition, the work of the appointment desk is closely coordinated with that of the clinic business office.

Frequently the information, registration, and appointment desks are combined, but they may be separate in large schools, or information and registration may be handled at one desk while appointments are made at a second. Similarly, one or more of these desks may be located either in the main waiting room or in adjacent rooms.

The reception area will require a records office. The convenience with which records can be dispatched to the clinics is an important consideration in the location of the area. However, storage space for inactive records need not be provided here, as these are frequently microfilmed or moved after two years to storage rooms in other areas of the school.

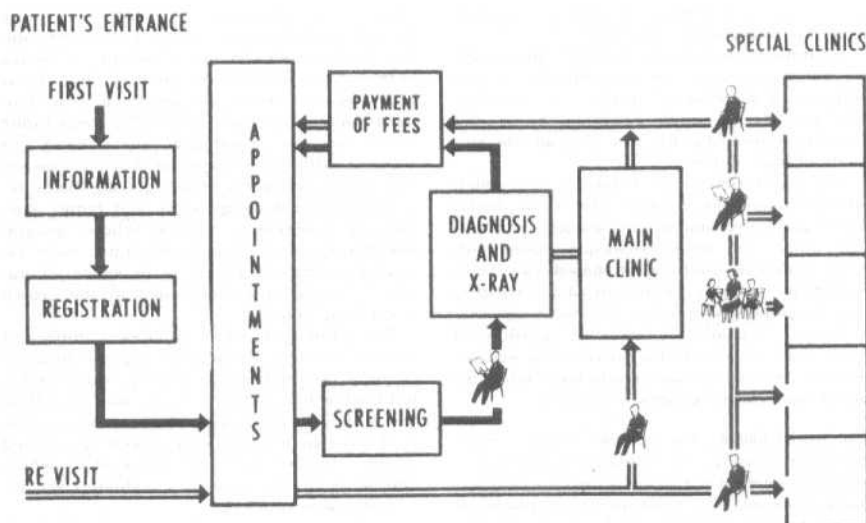

Fig. 9 Dental clinic flow diagram.

Screening. For the screening of new patients, an examination room separate from the diagnostic clinic is desirable. This room should be equipped with dental chairs. Dental units are not necessary unless the room will also be used for emergency treatment.

Emergency treatment rooms function as a part of the reception and screening area. Either a series of single-chair rooms or a large room with two or three dental chairs is practical. Although emergency treatment rooms are sometimes included in each of the clinics in the treatment area, the provision of central

facilities is more likely to assure that the rooms are not preempted for some other purpose.

Examination, Diagnosis, and Treatment Planning Area

It is in the diagnostic and radiology clinics that the incoming patient's need for dental care is determined and a plan of treatment formulated.

The Diagnostic Clinic Essential facilities in the diagnostic clinic include operatories or exami-

nation rooms, a clinical diagnostic laboratory, and a treatment planning and consultation room. Faculty offices and faculty research areas should be provided nearby.

Although multiple-chair rooms are sometimes used for examinations, a series of single-chair rooms assures privacy for the recording of patients' case histories. Each position should be equipped with an x-ray viewer. Estimating that 16 patients can be accommodated daily in each chair, an eight-chair facility could handle over 120 patients each day. In addition to dental chairs, the examination rooms should be furnished with desks for the convenience of those students who are recording case histories.

The clinical diagnostic laboratory is used for hematological and other diagnostic procedures. It is equipped with laboratory benches similar to those used for the low-bench basic science disciplines, but since students are assigned here in blocs, eight positions are usually sufficient. Air, gas, and electricity should be available at each position, and both hot and cold water are desirable. A hand washing sink should also be provided. One stand-up laboratory bench should be located at the outer wall. Because patients seen in this laboratory are referred directly from the diagnostic clinic, no waiting room is needed.

The treatment planning and consultation room, where students and instructors meet to discuss cases, should be equipped with a chalkboard, demonstration table, projection screen, and x-ray viewer, in addition to a dental chair and unit. The room can also be used for small-group demonstrations.

Radiology Clinic Because roentgenograms are made for every incoming patient, the radiology

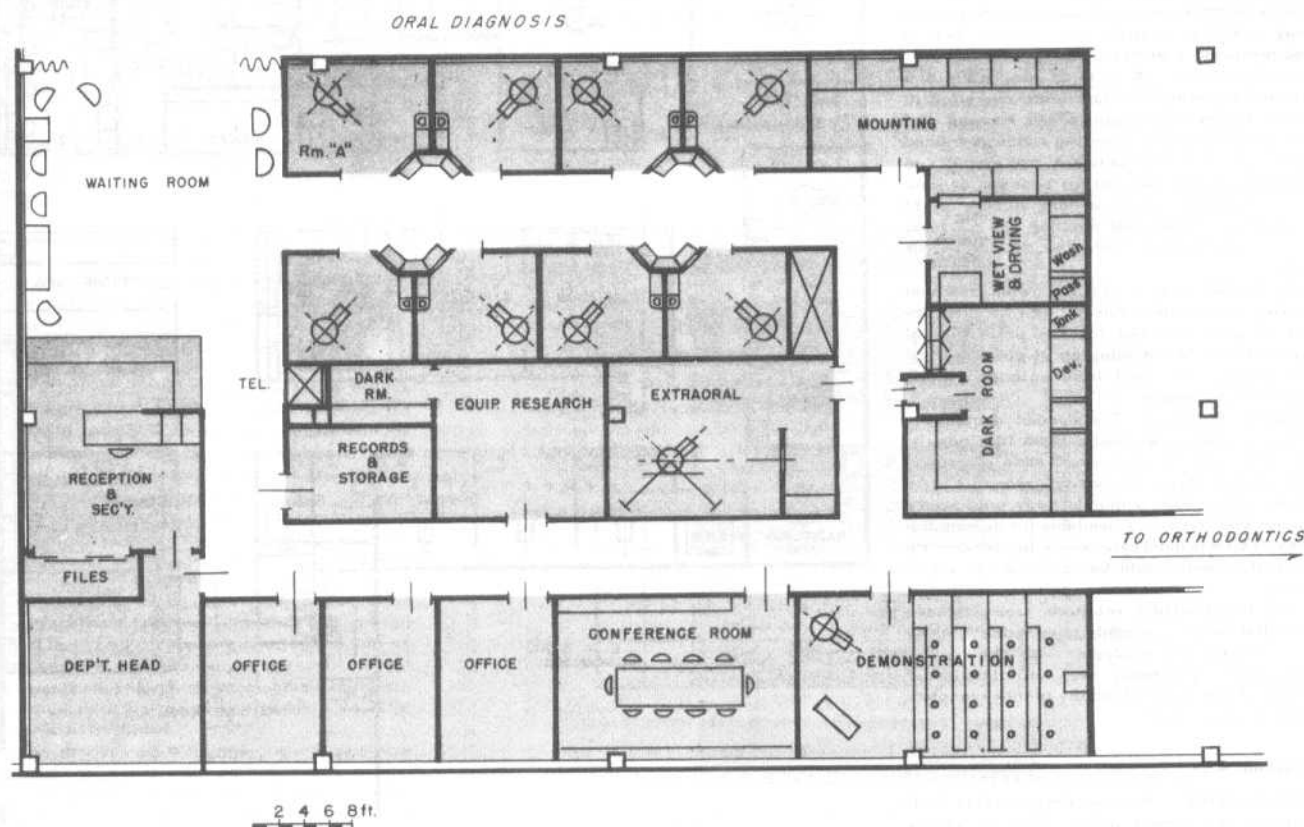

Fig. 10 Radiology clinic.

DENTAL SCHOOLS

clinic is included in the examination and diagnostic area. However, the radiology clinic also serves all the other clinics, and patients undergoing treatment are directed here for additional roentgenograms.

Shielding Against Radiation. Rooms containing x-ray machines must be shielded through the use of lead-lined walls and partitions or appropriate building materials of an adequate thickness. In addition, controls for x-ray machines should be located behind shielded partitions.

In general, shielding should be sufficient to limit the exposure of personnel to a minimum amount of radiation, certainly no more than 0.1 roentgen per week. In rooms equipped with 90 kvp x-ray machines, for example, the walls should be shielded with 1.2-mm sheet lead (3 lb per square foot) to a height of 7 ft. Stone concrete at least 3 in. thick should be used for ceiling and floor.

The Layout of the Clinic. Figure 10 shows the components and equipment of the radiology clinic. This plan includes eight rooms where the roentgenograms utilized in routine oral examinations are taken, and one extraoral radiology room.

In the radiology rooms, the machine is located behind the dental chair and up to 20 degrees to either side, the recommended position. Observation of the patient is made through a lead glass viewing window which has a speaking slot. Each of the rooms is equipped with a small chalkboard, illuminator, lavatory, and shelf. Room A, slightly larger than the others, has a 4-ft-wide opening to facilitate handling of wheelchair and stretcher patients.

The extraoral radiology room is of slightly greater depth than the intraoral, because a long-focus film distance is required for the facial-profile roentgenogram.

Each of these rooms is lead-shielded, and the x-ray machine controls are located behind lead-protected partitions.

Film Processing. A suite of rooms for film processing includes a darkroom, oversized to permit group instruction, a wet viewing and drying room, and a mounting room. A framed opening in the wall between the drying and mounting rooms is used for passage of film. The mounting room accommodates eight students. Each student position has a 14- by 17-in. view box built into the surface of the bench.

Air conditioning in the darkroom and wet viewing room is desirable not only for the comfort of personnel but for the protection of exposed film. Maintaining air at positive pressure will prevent dust from entering around windows and doors.

Ancillary Facilities. The special demonstration room, which accommodates 16 students, has provisions for movie and slide projection and closed-circuit television monitors. An exodontist's chair, a mobile x-ray unit, and a mobile lead screen are available for demonstrations. If ETV is used extensively for demonstrations, this room could be converted to a film library.

The departmental research area includes a small darkroom. A conference room, suitable for seminars and equipped with chalkboard, projection equipment, and an illuminated viewer, and a group of faculty offices complete the radiology clinic.

Treatment Area

The General Clinic Because the general clinic is typically the largest and busiest of all the clinics, the main waiting room and control

desks and many of the other elements already described are considered a part of it.

Treatment components include operatories, treatment planning and consultation rooms, supply and dispensing services, and sterilization and sterile supply facilities. Study and laboratory areas for the use of graduate students should adjoin.

The operatories, or work stations, into which all the clinics are divided, consist of dental chairs and units, instrument cabinets, sterilization units, and other necessary equipment. Each station should be large enough to accommodate the patient, the student who is treating him, the supervising instructor, and frequently a dental assistant. Several fully partitioned work stations should be provided to accommodate patients whose emotional reaction to dental care makes privacy mandatory.

The Special Clinics The special clinics—periodontic-endodontic, orthodontic, and others—are differentiated primarily by the type of treatment rendered. One, however, is distinguished by the type of patient treated—the chronically ill, the mentally disturbed, and others who are unable to receive treatment under regular clinical conditions.

The same departmental facilities and most of the treatment facilities required in the general clinic are needed for each of the special clinics. Every special clinic should have at least one fully partitioned work station. Generally, each will have a small waiting room with control desks separate from the main waiting room. However, related specialties such as pedodontics and orthodontics often share a waiting room.

Specific Requirements. Except for some variations in the design of the instrument cabinet, the basic equipment of the special clinics is the same as that of the general clinic. Most of the special clinics are equipped with standard dental chairs and units. The pedodontic clinic, however, requires a smaller chair and the oral surgery clinic special chairs or operating tables. And a few of the special clinics require additional components and highly specialized equipment. Clinics where general anesthetics are administered must have recovery rooms and toilets. A ceramics laboratory is sometimes maintained in the crown and bridge clinic.

The orthodontic clinic requires a number of special facilities. Among these are a measure room, a record room, a tracing room with a light table for routine tracing, and an office for technical personnel. This clinic usually contains two or more rooms with specialized equipment. At least one dental chair which can be used when general anesthetics are administered is required.

Frequently facilities for periodontic and endodontic treatment and for oral medicines are combined in one clinic. If x-ray machines are provided, the clinic must be shielded in the same manner as the radiology clinic or a lead-lined partition provided around the x-ray machines.

Oral Surgery Clinic: A Special Case. Perhaps the greatest variation in the components and equipment is found in the oral surgery clinic.

Figure 11 illustrates an oral surgery department planned to accommodate blocs of eight students. Eight of its nine operatories are equipped for surgery requiring local anesthe-

Fig. 11 Oral surgery department.

sics. Six of these, grouped in threes, are semi-enclosed. Folding partitions make full enclosure possible.

Of the three remaining operatories, the largest is equipped with an x-ray machine. Centrally located to the other operatories, this room is lead-lined. The demonstration operator is equipped for cases requiring general anesthesia as well as local. So is the adjacent operator (upper right). In addition, the demonstration operator is designed for closed-circuit television. A glass-enclosed gallery can be used for observation of treatment procedures, or as a control booth for television.

Both of the operatories equipped for general anesthesia are located adjacent to their supporting facilities. A scrub-up area is provided at the entrances. Nearby is the recovery area containing bunks and toilet facilities. A glass-partitioned nurse's station permits observation of patients. Also conveniently located are the sterilizing and sterile supply rooms, which serve only this clinic. Of the two rooms provided for storage of medication, one is used for narcotics and other medicines which must be kept locked.

Ancillary Facilities. Student facilities include a locker room with toilet, located near the secondary exit from the main operational area. The combination graduate student study area and laboratory accommodates four students. It contains desks, lockers, and a laboratory bench with a sink and electrical outlets. Locating the two administrative offices at the entrance to the clinic permits greater control and accessibility. A departmental research laboratory is provided, as in other clinical departments.

A patient waiting room seating 16 people would be adequate in a clinic of this type. Toilet rooms should be provided nearby. Although patients would normally enter and leave the clinic through the main waiting room, a secondary exit is provided for those requiring assistance after surgery.

Supporting Facilities

Central Supply and Dispensing Services Although each clinic in the treatment area will have its own small supply facilities, centralized service is necessary for the receiving and distribution of bulk supplies. Locating the central service near the clinics will permit greater efficiency. In a multistory building, stacking the smaller units on different floors will simplify the placement of service elevators and dumbwaiters.

Clinical Laboratories Most schools today believe the provision of two large general laboratories of full-class size—one for the juniors, one for the seniors—to be the most effective. Small separate laboratories in each of the special clinics are also a possibility. Schools should make every effort to see to it that each junior and senior student is provided with assigned, individually locked cupboards and supply drawers.

If the full-class laboratory for each of the upper classes can be provided, the design and layout will be approximately the same as that of the freshman-sophomore preclinical laboratories. Though no special demonstration position need be set aside, facilities for ETV should be included.

The processing laboratory, which contains special equipment such as heavy duty ovens, boilout tanks, and packing and curing units, must be large enough to accommodate not only students but the dental laboratory technicians employed by the school.

CLINICS: SPACE ALLOCATIONS AND RELATIONSHIPS

Dental educators today favor the adoption of the cubicle clinic. The privacy of the cubicle, a factor appreciated by patients as well as students, and the overall atmosphere of the cubicle clinic engender self-confidence and efficiency on the part of the student. (See Figs. 12 and 13.)

Planning the Cubicle Clinic

Influence of Dental Assistants Cubicles accommodating the student-assistant team must be narrower and deeper than those in which a

student works alone. The size (7 ft 6 in. by 7 ft 6 in.) and the arrangement of the cubicle in Fig. 15a, with the instrument panel at the right of the operator, is satisfactory for the dental student working alone.

The cubicles in Fig. 15b and c are planned for utilization of assistants. The cubicle in Fig. 15b, which is 6 ft 9 in. by 9 ft 2 in., is slightly narrower and deeper than the one in Fig. 15a. The added depth of the cubicle in Fig. 15b permits the location of the instrument cabinet and sink at the rear of the cubicle, convenient to the operator and the assistant. Figure 15c is another variation, adaptable to the 4 ft 8 in. planning module.

A cubicle clinic designed for utilization of

Fig. 12 Cubicle clinic.

Fig. 13 Variation of cubicle clinic.

Fig. 14 Cubicle clinic for utilizing dental auxiliary personnel.

auxiliary personnel is illustrated by Fig. 14. The location of the main and secondary aisles permits the instructor to move from one workstation to another without retracing his steps.

Cubicle Dimensions Cubicles in existing dental schools range in size from 6 ft 4 in. by 7 ft to 7 ft 8 in. by 9 ft 6 in. Where dental assistants will be used, a cubicle of 6 ft 9 in. by 9 ft 6 in. is desirable. For students working alone, a cubicle of 7 ft 6 in. by 7 ft 6 in. is adequate.

Cubicles may be either partially or fully enclosed. A partition height of approximately 5 ft is recommended for most cubicles. This provides privacy, yet allows for supervision and gives an impression of spaciousness. A 4-ft partition topped by a 1-ft-high translucent plastic panel may be used. Allowing an open space between partition and floor facilitates cleaning. However, one or two fully enclosed cubicles are desirable in every clinic.

Determining the Number of Clinic Positions

For the clinics as a whole, at least two operating positions should be provided for every entering class student—one in the general clinic and one in the group of special clinics.

Every school should also plan additional clinic positions for its graduate and postgraduate students. The equivalent of one student module is desirable in the general clinic for even a modest program of advanced study. Additional positions will also be needed in the special clinics, with the number dependent upon the goals of the school and the particular dental specialties emphasized in its graduate curriculum.

Estimating Space Requirements

Space allowances for each operating position will also vary in the different clinics. The diagnostic clinic will require 85 sq ft per position, an allotment also sufficient for oral surgery.

In the radiology clinic, 115 sq ft per position should be allowed, and in the clinic for the chronically ill and handicapped, 125 sq ft. For other clinics, an allowance of 100 sq ft per student position should be adequate.

Space allowance for some of the supporting facilities of the clinical departments will be fairly standard. For demonstration operatories, for example, a uniform allowance of 200 sq ft each may be used.

INSTRUCTION ROOMS, STUDY AREAS, AND LIBRARY FACILITIES

Seminars

The seminar is a room especially planned to accommodate small-group instruction for 16 students or less, usually at an advanced level of training.

In most schools, one or more seminar rooms will be needed for the use of each basic science department—at least one for instruction and perhaps one for departmental conferences.

In the clinical facilities of most schools, each of the special clinics will need one seminar room for treatment planning and consultation, and the general clinic will need more than one. In programming, a reasonable standard for the general clinic would allow four rooms for a class size of 96, increasing or decreasing the number by one for each 16-student module added or subtracted.

Allow a minimum of 300 sq ft for each seminar room, with increments of 75 sq ft for every four students beyond the 16 accommodated in the standard room.

Seating arrangements in seminar rooms are a matter of choice. Usually the instructor and his students sit around a central table, but some seminar rooms are furnished with standard tablet-arm chairs. Unitized folding tables and folding chairs permit maximum flexibility in seating arrangements, however, and their

use is increasing, especially in the seminar room used for showing slides, 16mm films, and other visual aids. If it is so used, a small adjoining room for storage of visual aid materials is also helpful. A seminar, like any other instruction room, should be equipped with a chalkboard.

Lecture Rooms

Although they accommodate a minimum of 50 people, all lecture rooms need not have the same capacity. The smallest should, however, seat at least a full class, plus an overrun of 20 percent. If the school expects a later expansion in class size, lecture rooms should be planned from the beginning to accommodate it, and the 20 percent overrun allowance should also be based on the larger figure.

A good rule of thumb is to provide seating capacity for one additional 16-student module beyond class size in schools with 96 ECS. An allowance of 12 sq ft per seat (roughly 200 sq ft for a student module of 16) is sufficient to permit an adequate aisle on either side of the seating area and, in a large lecture room, a center aisle as well.

A minimum of three lecture rooms should be provided, one for use of the basic science departments and located near them, one for clinical and preclinical instruction and accessible to the clinics, and one for special courses or for multiple use. In the school which will have no auditorium, the multiple-use lecture room might be designed to provide 2½ positions per ECS. All lecture rooms should be located so as to minimize noise and traffic congestion in the corridors.

Layout. It may be difficult to decide whether the lecture room should be long and relatively narrow, like the usual hall, or wider and shallower, like an amphitheater. Because of its wide viewing angle, the amphitheater is not particularly suitable for the showing of slides and films. On the other hand, instructors favor-

Fig. 15 (a) Cubicle for student working alone. (b) Cubicle for student and assistant. (c) Variation for student-assistant team.

ing the chalk talk technique often dislike a long room. Television monitors can be used in either type.

Every lecture room should be equipped with a large chalkboard; a minimum of 12 lin ft is recommended. If, because of the size of the room, a raised platform is provided, it should be long enough to extend 2 ft beyond each end of the chalkboard. Projection screens which can be automatically lowered and raised may also be a part of the permanent equipment.

The floors of lecture rooms should be sloped or terraced slightly to provide a good view of the chalkboards and projection screen.

Some larger lecture rooms are split level or have a balcony. Whenever possible, students should enter from the rear.

Furnishings. Fixed or movable tablet-arm chairs, or auditorium seats equipped with tablet arms, are commonly found in lecture rooms. If the latter are used, the aisle seat at the left of each row can be fitted with an outside tablet arm for the use of left-handed students. Writing counters with individual seats are also frequently used.

Auditoriums. For schools that have ready access to them, auditoriums sometimes serve as lecture or examination rooms. As a rule,

however, programming committees will find it difficult to justify a large auditorium solely for the use of a dental school, since it is generally more economical to rent a hall for occasions such as graduations which require large seating capacity.

If an auditorium is planned, it should be located on a ground floor. Direct entry from the outside is necessary, because the auditorium will often be used by the public when the remainder of the school is closed. Seating capacity should be sufficient to accommodate students enrolled in every program of the school as well as the total faculty.

Auditoriums must have public toilets and cloakrooms; a small lounge off the foyer is advisable. Areas for the preparation and storage of demonstration materials should be provided backstage, as should a toilet room.

Areas for Study, Reference, and Research

Study Areas Places for first- and second-year students should probably be located near the basic science laboratories, and those for third- and fourth-year students near the clinics. If possible, they should be so situated that students will have access to them at all times, even when the rest of the school is closed. **Space.** About 19 sq ft per ECS should be allowed in planning standard study places for a school providing one study place for every two students. This type of study place can be in a common room, and is usually unassigned. However, some schools may prefer the partially partitioned cubicle. Requiring approximately 48 sq ft per student position, the cubicles are furnished with a desk and chair, a coat locker, and storage space for books, microscopes, and school supplies. Because a cubicle is permanently assigned to each student, space requirements are based on the total enrollment.

Library Facilities The following guidelines, though general, may be helpful.

Reading and Study Rooms. The main reading room should accommodate from 25 to 50 percent of the total number of students. Reading room exits should be controlled by book

DENTAL SCHOOLS

charge-out or loan desks, and the card catalog and circulation desk should be nearby.

Carrels. Unenclosed desk areas of about 12 sq ft are useful for individual study and should be available in the ratio of one for every 10 students. Small study rooms reserved for graduate and postdoctoral students are also an advantage. Either they should be soundproofed or located far enough away from the main reading room to permit students to use typewriters without disturbing others.

Microfilm. Auxiliary facilities such as a microfilm reading room, a sound tape room, and a rare book room are also desirable.

Stacks. Stacks should be arranged to facilitate both storage and use of books. The stacks should be located as close to reading rooms as possible, preferably at or below the level of the main reading room.

Stack area varies in proportion to volumes. Generous allowances should always be made for future expansion. Stack sections are usually 3 ft in length and 7 ft 6 in. in height, with a shelf depth of at least 10 in. One single-faced section 3 ft long will accommodate approximately 100 volumes. Service aisles between stacks should be at least 3 ft wide, and the main aisles at least 3 ft 8 in. wide. A microfilm room for processing and storage may be associated with the stack area.

Other Facilities. Acquisition and catalog rooms should be near the public card catalog and have direct access to the stacks.

Offices should be provided for the head librarian and an assistant, with the head librarian's office accessible both to staff rooms and to readers. Storage space for office supplies should be available.

A library stocked with 25,000 volumes and amply supplied with space for reading rooms and auxiliary facilities would require approximately 10,000 sq ft for a school with 96 ECS.

EDUCATIONAL TELEVISION AND OTHER VISUAL AIDS

The location of the ETV department should be carefully chosen to hold distribution distances to a minimum. A top floor or penthouse would be a logical location. Preferably, the visual aids department should be nearby. The studio should not be less than 1,300 sq ft, completely visible from the control room. The ceiling height of the studio (13 to 14 ft) is another factor that must be considered in planning. One area of the studio should contain a dental operatory setup, with chair, unit, and instrument cabinet. A movable (on casters) laboratory demonstration bench will be required for demonstrations of experiments in the basic sciences. The televising of anatomical dissection will require a large overhead mirror. A smaller bench for dental technic demonstration, chalkboards, flip stand, and tack boards are additional requirements. Ample maneuvering area for the television cameras and operators must also be provided. Figure 16 shows an ETV department of approximately 2,500 sq ft.

The control room should be elevated and built as close to the ceiling as possible for maximum visibility. Entry into the control room should be possible without going through the studio.

Provision should be made for a film chain installation requiring a room approximately 12 by 15 ft. Kinescope recorders and videotape recorders should be planned for in areas adjoining the control room.

The amount of prop storage space required will vary with the emphasis placed on television and on the availability of other storage areas.

The director and assistant director will require office areas.

Visual Aids Department

The increasing use of ETV has not eliminated the need for a complete visual aids department, but has increased it. Figure 16 shows a visual aids department. In larger schools, 18 to 20 sq ft per ECS would provide centralized visual aids facilities for both the basic sciences and the dental science divisions.

Graphic Arts. Drafting tables, plan file cabinets, and a sink or lavatory should be provided.

Another room is needed for production of the three-dimensional models. A workbench with sink and utilities is required.

Photography. The room provided for the photographic section should be large enough to permit the photographing of patients, photomicrography, copying, film processing and printing, and print and slide finishing. It might also include equipment for preparing and projecting printed pages and similar opaque materials. The studio should be not less than 12 ft wide and approximately 35 ft long for making 16 mm motion pictures and for their projection.

Distribution and Storage of Visual Aids. Administrative offices are required for the maintenance of files and cataloging of material, control of distribution and the requisitioning of visual aids materials, and adequate space should be provided for storage of slides and films and for the storage, maintenance, and operation of all projectors.

SUPPORTING SERVICES FOR LABORATORIES AND CLINICS

The Feasibility of Centralized Laboratory Supply Services

Figure 17 is an example of a reasonable plan for a fully centralized laboratory service. Since the operation of four-student laboratories for all

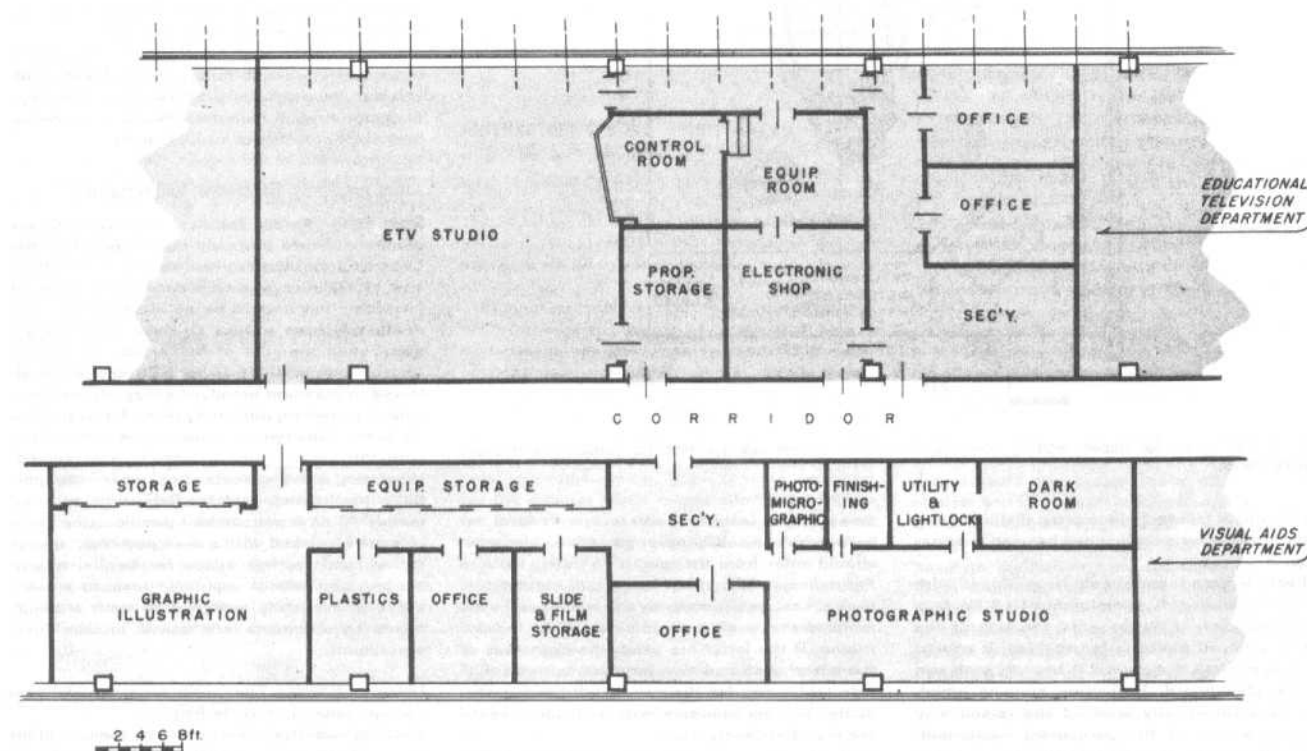

Fig. 16 ETV and visual aids departments.

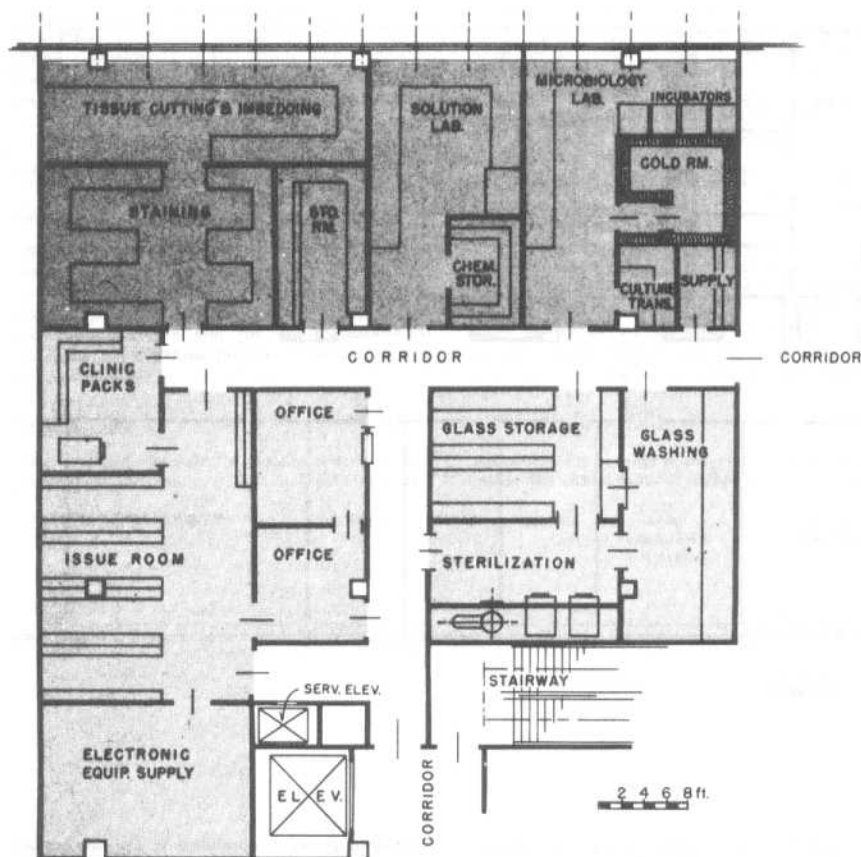

Fig. 17 Central laboratory services department.

basic science departments requires that equipment and supplies be in the individual laboratories prior to the beginning of a scheduled experiment, the central service facilities make delivery by placing each laboratory's equipment and supplies on trays. The trays are then placed on carts which circulate between the laboratories on regular delivery rounds.

Services Requiring Both Departmental and Central Facilities

Animal Quarters Although holding rooms for small animals adjoin research and teaching areas, a dental school must still provide one large and centrally located animal area.

To avoid the possible spread of disease, different species of animals should never be housed in the same room. Ideally, then, the central animal area should consist not of one large room but of a number of smaller ones. No room should be larger than 600 sq ft—a size which will amply accommodate 32 large dog cages.

Space requirements for smaller animals vary, and the following table provides examples of the net footage needed:

Mice	7 per sq ft
Guinea pigs	2 per sq ft
Rats	5 per sq ft
Rabbits	1 per 2 sq ft

In addition to this net space, allowance must be made for corridors and vestibules within the quarters, as well as for storage.

Storage places no major demand upon avail-

able space. Adequate facilities permit the storage of bedding, housekeeping supplies, and enough food for one day near the central holding rooms. Bulk storage is not necessary.

Ancillary facilities of the central quarters will, however, occupy substantial amounts of space. These should include a receiving or isolation room where animals can be held for observation during laboratory tests, and at least one adjoining small laboratory and perhaps more, depending upon the size of the school's research program.

There should be a small room for preparing food for the animals, and a much larger area for washing and sterilizing cages. The washers and sterilizers used here must be big enough to accommodate the largest cage. (Fixed cages, which must be washed within the holding rooms, are so arranged that refuse can be washed into a gutter and then into a flushing drain.)

Other facilities found in the larger animal quarters include animal surgery rooms, equipped with their own ancillary facilities for instrument sterilization and storage, recovery rooms, an autopsy room, an incinerator room, and a refrigerated storage area. Offices for a veterinarian and for an animal keeper are also provided.

The planning of the central animal area should not be undertaken without thorough consideration of such factors as insect and pest control, the reduction of noise and odors, and the sanitary disposal of refuse. Animal quarters should not be visible to the public, and they should be arranged so that the re-

ceiving of animals is simplified and the possibility of their escape minimized. The preferred location is on the ground level or in a properly air-conditioned basement area.

Technical Shops The technical shops are responsible for the upkeep and repair of the more complex equipment and devices employed by the various school departments. They also design and fabricate unique apparatus required for research and experimentation.

Though smaller shops of this type are attached to one of the basic science departments, the services of the central technical shops, with their larger staffs and more extensive equipment, should be available to all departments, including the basic sciences, of the dental school.

Even schools which do not require these specialized technical activities will need to provide the modest facilities required for the routine maintenance and repair of standard dental equipment, such as engines, lathes, and dental chairs. Because major repairs of this type are ordinarily made under contract, only limited equipment is necessary.

FACULTY FACILITIES

Office Facilities

A uniform allowance of 200 sq ft for each full-time faculty member will provide enough space to assure an individual office for each teacher with the rank of instructor or above as well as sufficient additional space for department heads and others with administrative responsibility.

Research Facilities

Space requirements for faculty research are particularly difficult to anticipate. An allowance of 100 sq ft for each full-time faculty member represents the equivalent of one small laboratory for each two teachers.

Function and Location

Faculty facilities are usually included in the area of major dental school activities, a location with obvious functional advantages (Fig. 18). If they are housed separately from undergraduate areas, however, future expansion of offices and research space is simplified. Also, if faculty facilities are grouped together in a separate area and their assignments controlled by the office of the dean, rather than by the department, the problem of transferring assigned facilities from one activity or faculty to another will be simplified. The relative merit of separate or departmentally integrated facilities should be carefully weighed before final decisions on exact locations are made.

GRADUATE AND POSTGRADUATE FACILITIES

In the basic science departments, an allowance of 150 sq ft per student will permit a two-module office and a four-module laboratory for each four graduate students. In the clinical departments, an allowance of 100 sq ft per student will permit one small combination study and research area for each four students. Additional operatories will also be needed.

Graduate programs should also be adequately provided with study cubicles and reserved library study rooms for the specific use of their students.

Fig. 18 Departmental office and research area.

AUXILIARY PERSONNEL

Training Facilities for Dental Hygienists

Dental hygiene students may share classroom space, facilities of the x-ray department, and the library, for example, with dental students. If ample laboratory space is available in the dental school, this, too, may be shared, although a separate laboratory for hygiene students facilitates class scheduling for courses like dental anatomy and prophylaxis techniques, which have heavy clock-hour laboratory requirements. The laboratory should be equipped with low benches having electricity, gas, and air outlets. Sufficient laboratory positions to accommodate an entire class are needed. A space allotment of 600 sq ft per 16-student module should be adequate.

The clinic space for the dental hygiene program may be either in a section of the main clinic or in a separate clinic.

If any increase in enrollments is planned for a later date, enough space should be allocated originally and utilities installed to provide for the added students, even though all space is not immediately equipped.

Hygienists will require lounge, locker, and toilet facilities. In some schools, they will share these facilities with other women.

The careful location of a hygiene clinic is one way of providing flexibility in school planning. If, at some later date, it should become necessary to expand the school's clinical facilities, the dental hygiene clinic can be relocated and its former facilities incorporated into other clinics.

ADMINISTRATIVE FACILITIES

One of the focal points of dental school activity is the administrative area. Though it should be readily accessible to visitors, it need not be

in a predominant location. In some schools, it is located on an upper floor, convenient to an elevator or stairway.

In general most dental schools will to some extent undertake duties which fall into three broad categories—academic policy, student affairs, and business and personnel management.

Academic Offices

In planning the office of the dean, space must be allotted for the dean's private study and for his secretary—with due regard paid to the need for bookshelves, filing space, and office supply storage. A conference room may also be necessary. In addition, offices will be required for an assistant or associate dean and his secretary. Whether or not the dean's offices should be grouped so that the secretarial staff may share a large single office is a decision for the individual school. In programming, approximately 1,500 sq ft should be adequate for these rooms. In larger schools, an office for another assistant dean may be needed.

Where the programs warrant it, graduate and postgraduate divisions will have their own officers and offices, and extensive research activity will require a research coordinator, who will also need an office. Schools training dental hygienists or dental assistants will need office accommodations for the director of these programs. Some schools also include an office for part-time faculty members in the administrative area. In programming, allow 200 sq ft for each office and 300 sq ft for each conference room required in connection with these programs.

Student Affairs

Schools which do not depend upon the university for such services will require a registrar's

office to process applications for admission, to supervise registrations, and to maintain student records.

Many schools also offer active programs of student assistance, including counseling and advisory services, and office space is required for the professional personnel who conduct them. In some schools, offices are provided for the chaplains appointed to serve their students. All schools will probably need space to house expanding scholarship and loan activities, and, in some, additional space will be needed to handle student housing services. In small schools or in schools with very limited responsibilities for directing student affairs, these activities will probably be combined with those of a business or personnel office.

Business and Personnel Management

Some schools have little more than a cashier's office and a minimum of clerical help. Others maintain a complex accounting and fiscal operation, headed by the office of the bursar.

A public relations department, personnel offices, and stenographic-dictaphone pools may also be needed in larger institutions. Adequate space for stock rooms and administrative records is always essential. The advisability of employing an administrative director of clinics should be considered, and some schools today strengthen this service by adding a social worker.

In some activities—printing and publications is one—the type of equipment largely determines space needs. Offset printing presses will be desirable in some schools; others need little more than mimeograph machines, and their space requirements will vary accordingly.

Mail rooms which consistently handle bulk mailing require a special space allotment.

The actual allocation of space for the various business functions and for the administration

of student affairs will vary widely. For the average school, however, total space needs for these two groups of functions will probably be adequately met by an allowance of 25 sq ft per ECS.

STUDENT FACILITIES

Bookstores

For most schools, an allowance of from 8 to 10 sq ft per ECS—with a minimum of 500 sq ft—is a good preliminary estimate of bookstore space. This will provide room enough both for open displays and for some storage. If possible, the store should be located near the student lounge or the cafeteria.

Student Lounges

The student lounge is important—perhaps indispensable—to a dental school, and the

availability of similar facilities elsewhere on the campus does not, in this case, reduce the need for a lounge in the dental school itself. The lounge is the students' social center.

Although the number of women enrolled in undergraduate dental schools is small, schools should provide separate lounges for their convenience. In some schools, women dental students will be able to share the lounges provided for student dental hygienists and dental assistants.

In programming, the committee should estimate lounge space at 23 sq ft per ECS for a class size of 96. For classes of different sizes, 200 sq ft should be added or subtracted for each group of 16 students. These amounts permit simultaneous occupancy by approximately 25 percent of the total enrollment.

Locker Rooms

Adjoining the lounge areas should be adequate toilet facilities and—if feasible—the student

locker rooms. Locker rooms should at least be convenient to the part of the school where the student spends most of his academic day—near the basic science and preclinical technique laboratories for freshmen and sophomores, near the clinics and associated clinical laboratories for juniors and seniors.

The locker room area required for male students can be estimated at 1,800 sq ft for an entering class of 48 (or three 16-student modules); this amount should be increased by 500 sq ft for each additional group of 16 students.

As to the lockers themselves, the types chosen should depend on the use to which they are put. If dental students are expected to keep their instrument cases in clothing lockers, the size of the case should be established and a prototype made so that the suitability of the lockers can be tested before they are purchased. The lockers chosen should also be large enough to accommodate other dental equipment.

INTRODUCTION

This section deals with design for the following nursing programs, respectively: the diploma, associate degree, baccalaureate and graduate degrees, and practical nursing. In each section, a description is presented of special aspects of each program. A hypothetical school has been described and space requirements determined. No attempt was made to compare the space requirements of one program with another, since each has its special needs, precluding a common basis for comparative purposes. For example, each program differs in purpose, curriculum, and graduation requirements.

The second half of this chapter sets forth planning considerations which will affect the architectural design of a facility. No attempt is made to outline finished plans since this should be the decision of the individual school, after a careful evaluation of various alternatives. Moreover, before the architect begins to develop his plans, the school must first establish its educational program.

DIPLOMA NURSING PROGRAMS

The diploma nursing program is conducted by a single-purpose school and may be either hospital-sponsored or independently incorporated. This program serves the interests and needs of qualified high school graduates who want (1) an education centered in a hospital, and (2) an early and continuing opportunity to be with patients and with personnel who provide health services. (See Fig. 1 and Table 1.)

Program Characteristics

Diploma programs emphasize the basic scientific principles of nursing care and of recognizing indications of diseases, disabilities, and patient needs. The curriculum is planned to equip graduates with the skills necessary to organize and implement a nursing plan that will meet the immediate needs of one or more patients, to be responsible for the direction of other members of the nursing team, and, to the degree possible, to promote the restoration of the patient's health.

Some graduates of diploma programs may wish to fulfill requirements for a baccalaureate degree in nursing. Admission is granted in accordance with the admission policies of the particular college or university they wish to attend.

THE ASSOCIATE DEGREE NURSING PROGRAM

The associate degree nursing program is generally established as a division or department of a community junior college, although some are in four-year colleges or universities. This program is designed to fulfill the educational

needs of qualified high school graduates who want (1) to prepare to practice nursing as registered nurses, and (2) to study in a college where they may share responsibilities and privileges as well as intellectual and social experiences with students in other educational programs. (See Fig. 2 and Table 2.)

Program Characteristics

The following characteristics identify associate degree nursing programs:

1. The college controls, finances, and administers the program.
2. The program conforms with the overall standards and policies of the college and operates within the framework of its organization, administration, interdisciplinary curriculum committees, and the student personnel program.
3. The policies and procedures promulgated for faculty in other college departments also apply to the nursing faculty.
4. Members of the nursing faculty plan, organize, implement, and teach the nursing courses. They select, guide, and evaluate all learning experiences including those in the patient care areas.
5. The college, by means of written agreements with hospitals and other agencies in the community, provides clinical facilities essential to nursing education.
6. Students meet the requirements of the college and its nursing department for admission, continuation of study, and graduation.
7. The nursing program is organized within the framework of the community junior college curriculum pattern leading to an associate degree.

Graduates of the associate degree nursing program are prepared to give patient-centered nursing care in beginning general-duty nurse positions. They are prepared to draw upon a background from the physical, biological, and social sciences in administering nursing care to patients. They relate well with people and are self-directive in learning from experience as practicing nurses. They are prepared to cooperate and share responsibility for the patients' welfare with other general-duty nurses, head nurses, supervisors, attending physicians, and others. As all other beginning practitioners, these graduates need to be oriented to new work situations and given time and opportunity to become increasingly effective in the practice of nursing.

The program is complete for its purpose. Some graduates from associate degree programs may later wish to fulfill requirements for a baccalaureate degree in nursing.

BACCALAUREATE AND GRADUATE NURSING PROGRAMS

Program Characteristics

Undergraduate Programs A nursing program leading to a baccalaureate degree is conducted by an educational unit in nursing (department, division, school, or college) that is an integral part of a college or university and is organized

and controlled in the same way as other units in the institution. (See Table 3.)

The baccalaureate degree program is designed to serve the needs and purposes of persons who want (1) to learn and practice the humanistic and scientific bases for care of patients, (2) to prepare for nursing at the baccalaureate level, (3) to share with students preparing for other occupations all the general advantages of a college or university preparation, and (4) to acquire a baccalaureate education as a prerequisite for graduate study to prepare to practice in such specialties as teaching, administration, or research.

Graduates of baccalaureate programs are prepared for nursing positions in community health services and may advance without further formal education to positions, such as head nurse and team leader, which require administrative skills. Graduates also have a foundation for continuing personal and professional development and for graduate study in nursing.

Some graduates of associate degree and diploma programs in nursing may wish to fulfill requirements for a baccalaureate degree in nursing. Admission requirements vary with different colleges and universities.

Graduate Programs A graduate nursing program is organized similar to other graduate programs within the university. With only few exceptions, these are offered in conjunction with a baccalaureate nursing program. (See Table 4.)

The graduate program is designed to prepare nurses for leadership positions in teaching and administration in all types of educational programs. Such a program also provides an opportunity to study for supervisory and administrative positions in nursing service. Consultants, clinical specialists, and research workers also require graduate study.

(See Fig. 3.)

PRACTICAL NURSING PROGRAMS

Seventy-five percent of the state-approved nursing programs leading to a practical nurse certificate are controlled by educational institutions or agencies. The majority are under state and local boards of education. The remainder are mostly under the control of hospitals, with the exception of about six which are under other community agencies. (See Tables 5 and 6 and Figs. 4 and 5.)

Program Characteristics

The practical nursing program which leads to a certificate or diploma is usually one year in length, self-contained, complete, and satisfactory for its own purpose, providing preparation exclusively for practical nursing. (California and Texas call these programs "Vocational Nurse Programs" and license the graduates as Licensed Vocational Nurses.) This program's objective is to prepare a needed worker in nursing service who will share in giving direct care to patients. Graduates of practical nursing programs perform two major functions:

TABLE 1 Space Requirements for a 3-Year Diploma Program with a Total Entering Class of 64 and a Total Enrollment of 148

Spaces	Nursing education area			Remarks
	Number of rooms	Group size, each room	Total net area (sq. ft.)

Students' health service.....	-	-	-	Shared with faculty.
Staff lounge.....	-	-	-	
Visitors' toilets:				
Men.....	1	-	40	1 watercloset, 1 lavatory.
Women.....	1	-	40	1 watercloset, 1 lavatory.
Supporting.....	-	-	1,580	
Students' toilets:				
Men.....	1	-	120	1 watercloset, 1 lavatory, including 10 full-size lockers.
Women.....	1	-	280	7 waterclosets, 7 lavatories.
Students' lounge.....	1	-	300	
Lockers.....	-	-	240	30 full-size lockers.
Janitors' closets.....	1	-	40	Or as required.
Coat alcoves.....	-	-	-	As required.
Vending machines.....	-	-	-	As required.
Telephone booths.....	-	-	-	As required.
Drinking fountains.....	-	-	-	Minimum of 4—recessed or as required.
General storage.....	1	-	600	
			14,847	Net area.
			9,808	For walls, partitions, corridors, stairs, and mechanical space.
			24,745	Total gross area.
			167.2	Area per enrolled student.

If the sciences are taught in the home school, add the following:

Teaching.....	-	-	4,368	
Classrooms.....	1	38	648	
Science laboratories.....	2	-	3,600	These should be added if the sciences are taught in the home school.
Storage and preparation room.....	1	-	120	
Faculty.....	-	-	500	
Offices.....	5	1	500	
			19,215	Total net area.
			12,810	For walls, partitions, corridors, stairs, and mechanical space.
			32,025	Total gross area.
			216.4	Area per enrolled student.
Assembly room.....	1	200	3,000	Flat floor.
			22,215	Total net area.
			14,810	For walls, partitions, corridors, stairs, and mechanical space.
			37,025	Total gross area.
			250.2	Area per enrolled student.

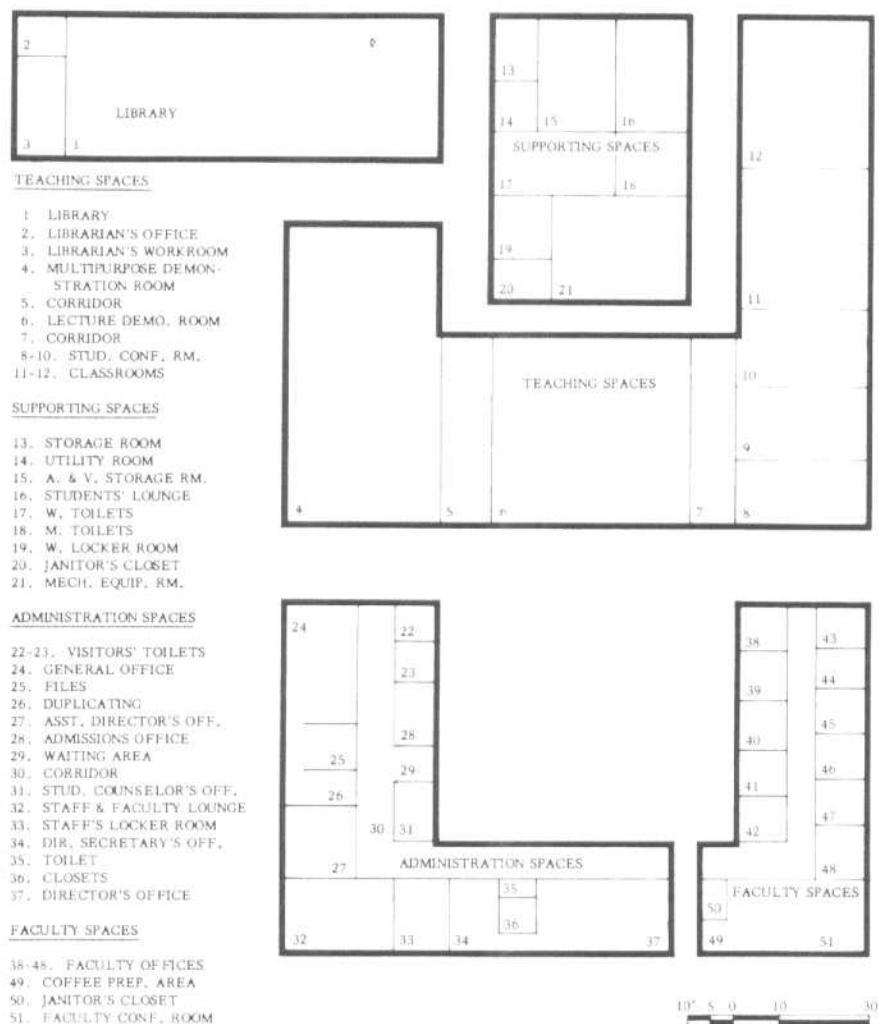

Fig. 1 Space relationships in the diploma program.

1. Under the direction of a registered nurse or physician, they administer nursing care in situations relatively free of scientific complexity.

2. In a close working relationship, they assist registered nurses in providing nursing care in more complex situations.

ARCHITECTURAL CONSIDERATIONS

The physical essentials of the various spaces required for any type of program of nursing education are briefly described in this section. All the spaces noted, however, are not necessarily required for all programs. Moreover, many of the spaces may be used in conjunction with other departments of a community college, a university, or institution to which the nursing education program is related. Where possible, variations are noted.

The diagrams of teaching spaces are only suggestive of one method of arranging these spaces. The final scheme used by a nursing education program will depend on its particular needs expressed in the written program. The

degree to which the architect can effectively design a facility depends largely on how thoroughly the functional program of the proposed facility was prepared.

Although each nursing education facility will find it necessary to determine its own space requirements in light of its own needs, the spaces required by most schools might be grouped under seven categories. These categories include teaching spaces, research facilities, faculty offices, administrative unit, students' facilities, supporting areas, and continuing education.

Teaching Spaces

Lecture-Demonstration Rooms The lecture-demonstration room (Fig. 6) is used for the purpose implied in its name. Factors to be considered in determining physical dimensions are requirements for the following: (1) teaching station, (2) demonstration area, (3) seating area, (4) projection space or room, and (5) storage closets. A brief description of each follows:

Teaching Station. The teaching station should be equipped with chalkboards, tack

boards, projection screens, and map rails above to support diagrams and charts.

Demonstration Area. The demonstration area in front of the teaching station should be large enough to permit the use of equipment such as an adult-size bed or movable sectional counter units which have locking wheels. These units, which have storage space underneath, provide greater flexibility than fixed counters, since they can be assembled into any arrangement or length and can be stored elsewhere when not in use.

A lavatory will be needed in the lecture-demonstration area for use whenever a patient care demonstration is presented. The doors into this room should be a minimum of 3 ft 8 in. wide to provide an adequate passageway for a bed and other equipment used during a demonstration.

Seating Area. Since good visibility of the instruction and demonstration area should be assured from all seats, a stepped floor should be considered. Steps should be so designed that each sight line misses the row ahead by 4 in. Fixed seats equipped with hinged or removable tablet supports for writing are recom-

TABLE 2 Space Requirements for a 2-Year Associate Degree Program in a Community College with an Entering Class of 64 and a Total Enrollment of 104

Spaces	Nursing education area			Remarks

General storage.....	1	—	600	
			9,840	Net area.
			6,560	For walls, partitions, corridors, stairs, and mechanical space.
			16,400	Total gross area.
			157.7	Area per enrolled student.

mended. Ten percent of the seats should be for left-handed students.

Projection Room. A projection room separated from the classroom is desirable because it eliminates such disturbing factors as noise and light. However, certain disadvantages of a separate projection room such as the need for an operator and for communication facilities between the operator and the instructor should be considered.

In lieu of a projection room, a console for projection equipment is a good compromise. This console will contain all lighting and projection controls and will have locked storage space for equipment when not in use.

If such a room is provided, it may also be used for editing and storing material to be projected. Provision, therefore, should be made for counters with storage space underneath. One of the counters should have a sink. Open shelves or wall cabinets with glazed doors may be provided above the counters.

The projection wall should have two small windows so that two projectors can show two images on the screens simultaneously. The width of the screen should be approximately

equal to one-sixth of the distance to the last row of seats. Projection screens can be the roll-up type, either manually or mechanically operated, or the fixed type. Mechanical operation, although noisy, prevents accidental damage to the screen.

Storage Closets. Storage closets with standard-height doors may be provided. Among other things, skeletons and full-scale models of the human body may be stored here if there is no centralized storage.

Classrooms. The classroom (see Fig. 7) should provide an optimum setting for communication between the instructor and the students.

The room's shape and size should permit easy visibility of written material on the chalkboard as well as the projected image on the screen. The need to maintain as close a verbal distance as possible between students and the instructor should also be considered.

Acoustical treatment to support verbal communication and sound insulation to prevent the penetration of outside noises must be considered in selecting structural and finish materials.

In addition to the floor area required for seating, space should be allocated for teaching and demonstration and for mounting a projector.

If central storage of such teaching aids as skeletons and full-scale models of the human body is not provided, storage closets will be required in classrooms.

A lavatory should be provided in the room near the teaching station so that it will be easily accessible for use whenever patient care is being demonstrated.

The classroom door should be a minimum of 3 ft 8 in. wide to permit easy transportation of an adult-size bed which may be required for demonstration.

Equipment which will be needed for classrooms includes chalkboards, tack boards, and projection screens. x-ray film illuminators, either portable or wall mounted, may also be used.

Multipurpose Room The multipurpose room (see Fig. 8) may be used for student practice of patient care as well as for classroom functions. Thus, the room should accommodate:

NURSING SCHOOLS

1. Adult-size beds which may be separated by curtains suspended from ceiling curtain tracks.

2. A medicine preparation area including movable sectional counter units and fixed counters located at the wall, with sink and storage cabinets underneath and wall cabinets with glazed doors above.

3. A handwashing demonstration unit and a minimum of three lavatory basins, with foot, wrist, or knee control.

4. Dressing cubicles. One method for providing privacy is through the use of curtains suspended from ceiling curtain tracks.

5. Storage closets for small equipment, linen, charts, and diagrams. These closets should have a full-size door and should be large enough to store skeletons and full-size models of the human body, if necessary.

6. Chalkboards, tack boards, projection screens.

7. Seating around tables for seminar-type lectures for 16 students.

8. Space for projector mounting.

X-ray film illuminators may be used in all teaching areas. They can be either wall mounted or portable. If portable, storage space should be allocated for them when not in use.

Utility Room. The utility room can either be a part of the multipurpose demonstration room or may be separated by a solid partition.

Although each facility must determine its own specific equipment needs, the following built-in features are recommended:

1. A counter with sink and storage underneath with wall cabinets above

2. Roughed-in plumbing to accommodate future fixtures

Students' Conference Rooms (Teaching) Student conference rooms will be required in all programs. (See Fig. 7.) The number of such rooms will depend on the anticipated enrollment. Major planning considerations include:

- Seating arrangement at tables for group discussions or lectures
- Placement of chalkboards and tackboards
- Adequate sound isolation from one room space to another

Science Laboratories Students enrolled in associate and baccalaureate degree programs in nursing attend science courses with other undergraduates. The trend in diploma programs is to purchase instruction in the sciences from a local junior college, a college, or a university. To avoid the unnecessary duplication of expensive facilities, diploma programs should plan science laboratories only if such facilities are not available from other institutions. (See Fig. 9.)

Library Library facilities are required in all nursing education programs. Wherever feasible, a library may be shared with other types of programs; however, the diploma school will usually have its own library. An example of library facilities for a diploma program is shown in Fig. 10.

The information presented is considered minimum for the needs of a nursing education facility whether it is part of a larger library or an independent library. In any event, future expansion should be a major planning consideration.

Principal elements to be considered in designing a library include (1) the library room; (2) the librarian's office; (3) the librarian's workroom; and (4) the storage area for audiovisual equipment and models.

Library Room

Reference and Study Area. Study space should accommodate a minimum of one-third of the total student body. Reference tables may be provided for one-half of these students and carrels for the other half. Teaching machines may be used in carrels.

The reference and study area should occupy 55 to 60 percent of the total floor space of the library room.

Service Area. Card catalog and circulation activities should be located near the library entrance and reading area.

Storage Area. All nursing programs should have an adequate amount of space for stacks to accommodate necessary titles and bound volumes of periodicals. Appropriate filing arrangements should be provided for reports, pamphlets, bulletins, microfilms, microcards, and programmed material for teaching machines. For the diploma program, stacks should be provided for a minimum of 3,000 titles and 1,000 bound periodical volumes.

TEACHING SPACES

1. CLASSROOM
2. MULTIPURPOSE DEMONSTRATION ROOM
3. PROJECTION ROOM
4. LECTURE DEMO. ROOM
- 5-7. STUDENTS' CONF.

SUPPORTING SPACES

8. UTILITY ROOM
9. STORAGE ROOM
10. MEN'S ROOM
11. WOMEN'S TOILETS
12. MECH. EQUIP. ROOM
13. A. & V. STORAGE ROOM

ADMINISTRATION SPACES

Conference room.....	-	-	-	Optional.
Lounge and reception area.....	-	-	700	
Toilets.....	-	-	-	
Men.....	1	-	130	1 watercloset; 1 urinal; 1 lavatory.
Women.....	1	-	130	1 watercloset; 2 lavatories.
Drinking fountains.....	-	-	-	
			24,044	Total net area.
			16,029	For walls, partitions, corridors, stairs, and mechanical space.
			40,073	Total gross area.
			166.97	Area per enrolled student, approximately 167 sq. ft.

Librarian's Office

The librarian's office should be separated from the library room by a glazed wall partition or a view window to enable the librarian to oversee activity in the library. The office should be sufficiently large to accommodate several people for an informal conference and should be equipped with necessary furniture including bookshelves, desk, and typewriter stand.

Librarian's Workroom

The workroom should be adjacent to the library room and to the librarian's office. Direct access should be provided into the corridor to permit easy deliveries by either a 3-ft 8-in. clear opening or double doors.

The room should include:

- Counter worktop with sink and storage cabinets underneath; part of the counter should have knee space underneath
- Storage shelves or wall cabinets above
- Adequate number of electrical outlets
- Space allocation for desk, worktables, movable book carts

Reference Reading Room

Nursing education programs which use adjacent library facilities may need only a small reference-reading room in the nursing education facility. Standard references and professional periodicals should be kept in this room, where study space should also be provided.

Equipment such as shelves, storage cabi-

nets, reference tables, and seats around tables for 16 people should be provided.

Storage Area

Some nursing education programs may wish to centralize all teaching aids under the librarian's supervision. Such a center is sometimes referred to as the Instructional Materials Center (IMC). If provisions for storing skeletons and full-scale models of the human body are not made elsewhere (i.e., lecture-demonstration room, classrooms, or multipurpose demonstration room), a central storage facility should be provided. This room should be placed close to the library and should be equipped with sturdy open shelving to hold heavy equipment. In planning the space to be

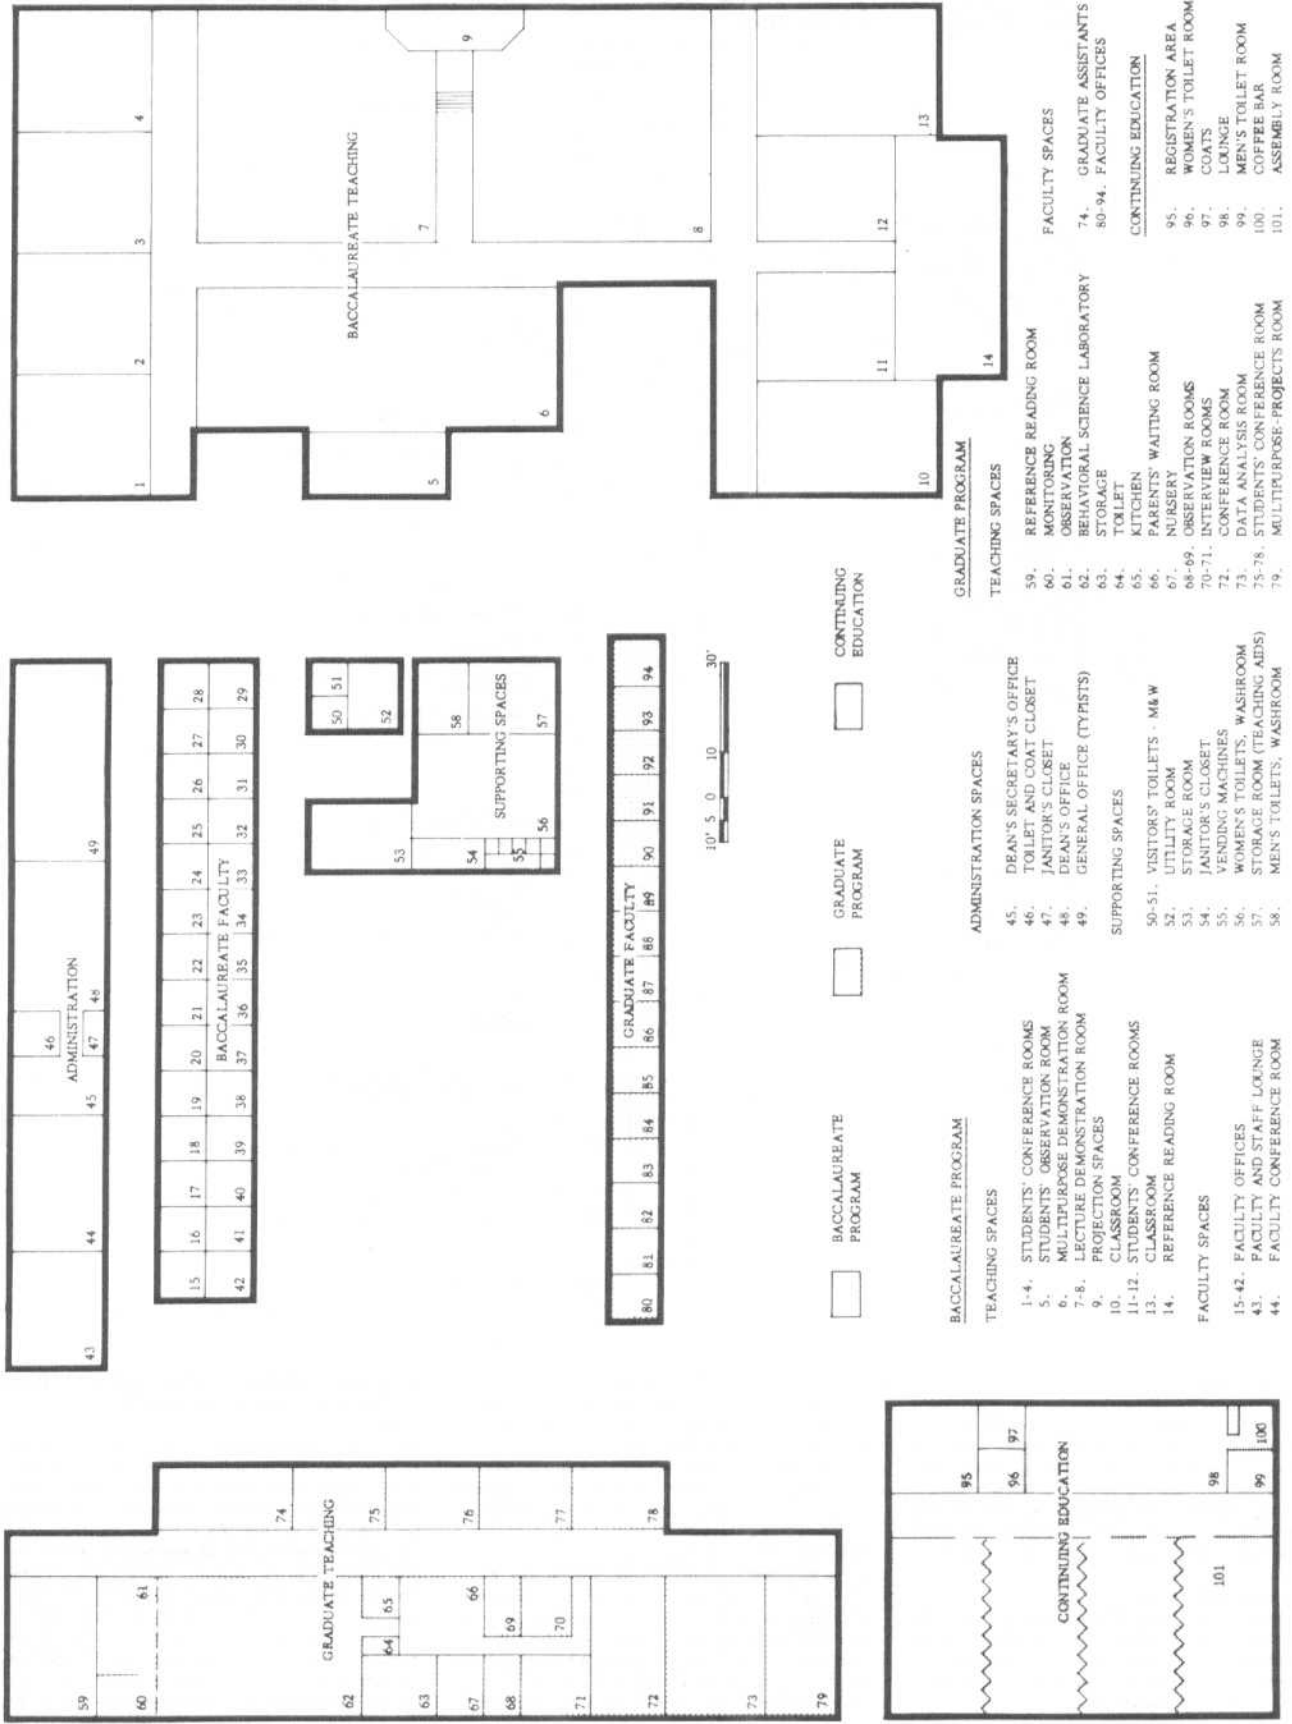

Fig. 3 Space relationships in baccalaureate, graduate, and continuing education programs.

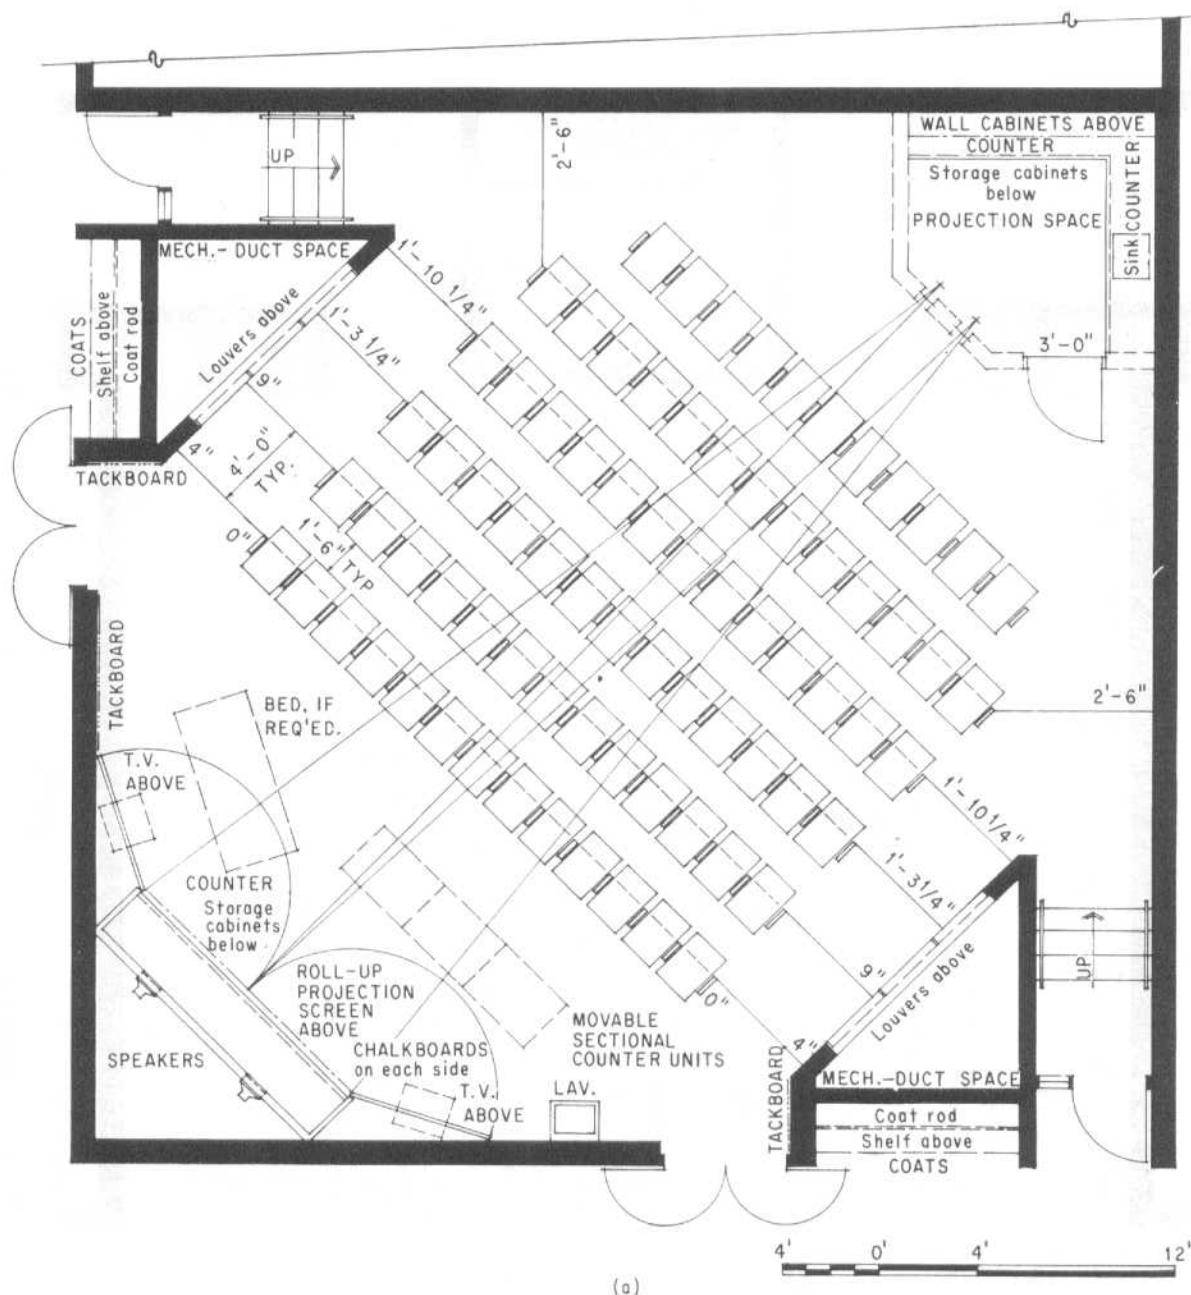

Fig. 6 Lecture-demonstration rooms.

provided for storing charts and diagrams, consideration should be given the need for easy identification and accessibility.

Full-scale skeletons and models of the human body, preferably mounted on a small cart for easy transportation, should be stored in full-size closets. Small models of parts of the human body may be stored in wall cabinets with glazed doors for easy identification. It may be preferable to store certain audiovisual items within the room in which they are used. In addition, a general storage area or room is required, and provision for storing teaching machines should be made.

A building with more than one story will need at least one service elevator for transporting heavy equipment.

Research Facilities

Research facilities will be required only by the baccalaureate and graduate nursing education programs. Typical laboratory arrangements are shown in Fig. 11.

In some instances, nursing education programs will need to develop research facilities either for graduate students or faculty members. The amount of laboratory space required depends upon the type of research program offered. Therefore, before architectural plans are developed, the needs should be carefully evaluated and defined by the faculty members and others who will use the laboratory facilities.

The building program for research facilities

will vary among schools since it must be based on each school's individual requirements. Research facilities may include:

- Biological science laboratories
- Behavioral science laboratories
- The data analysis room including offices and conference room
- Multipurpose project room(s)

Biological Science Laboratories Biological science laboratories will need the following spaces:

- Separate offices for each researcher
- Storage or supply preparation room to serve several laboratories, for equipment, glassware, and supplies
- Deluge shower and eye bath for emergencies

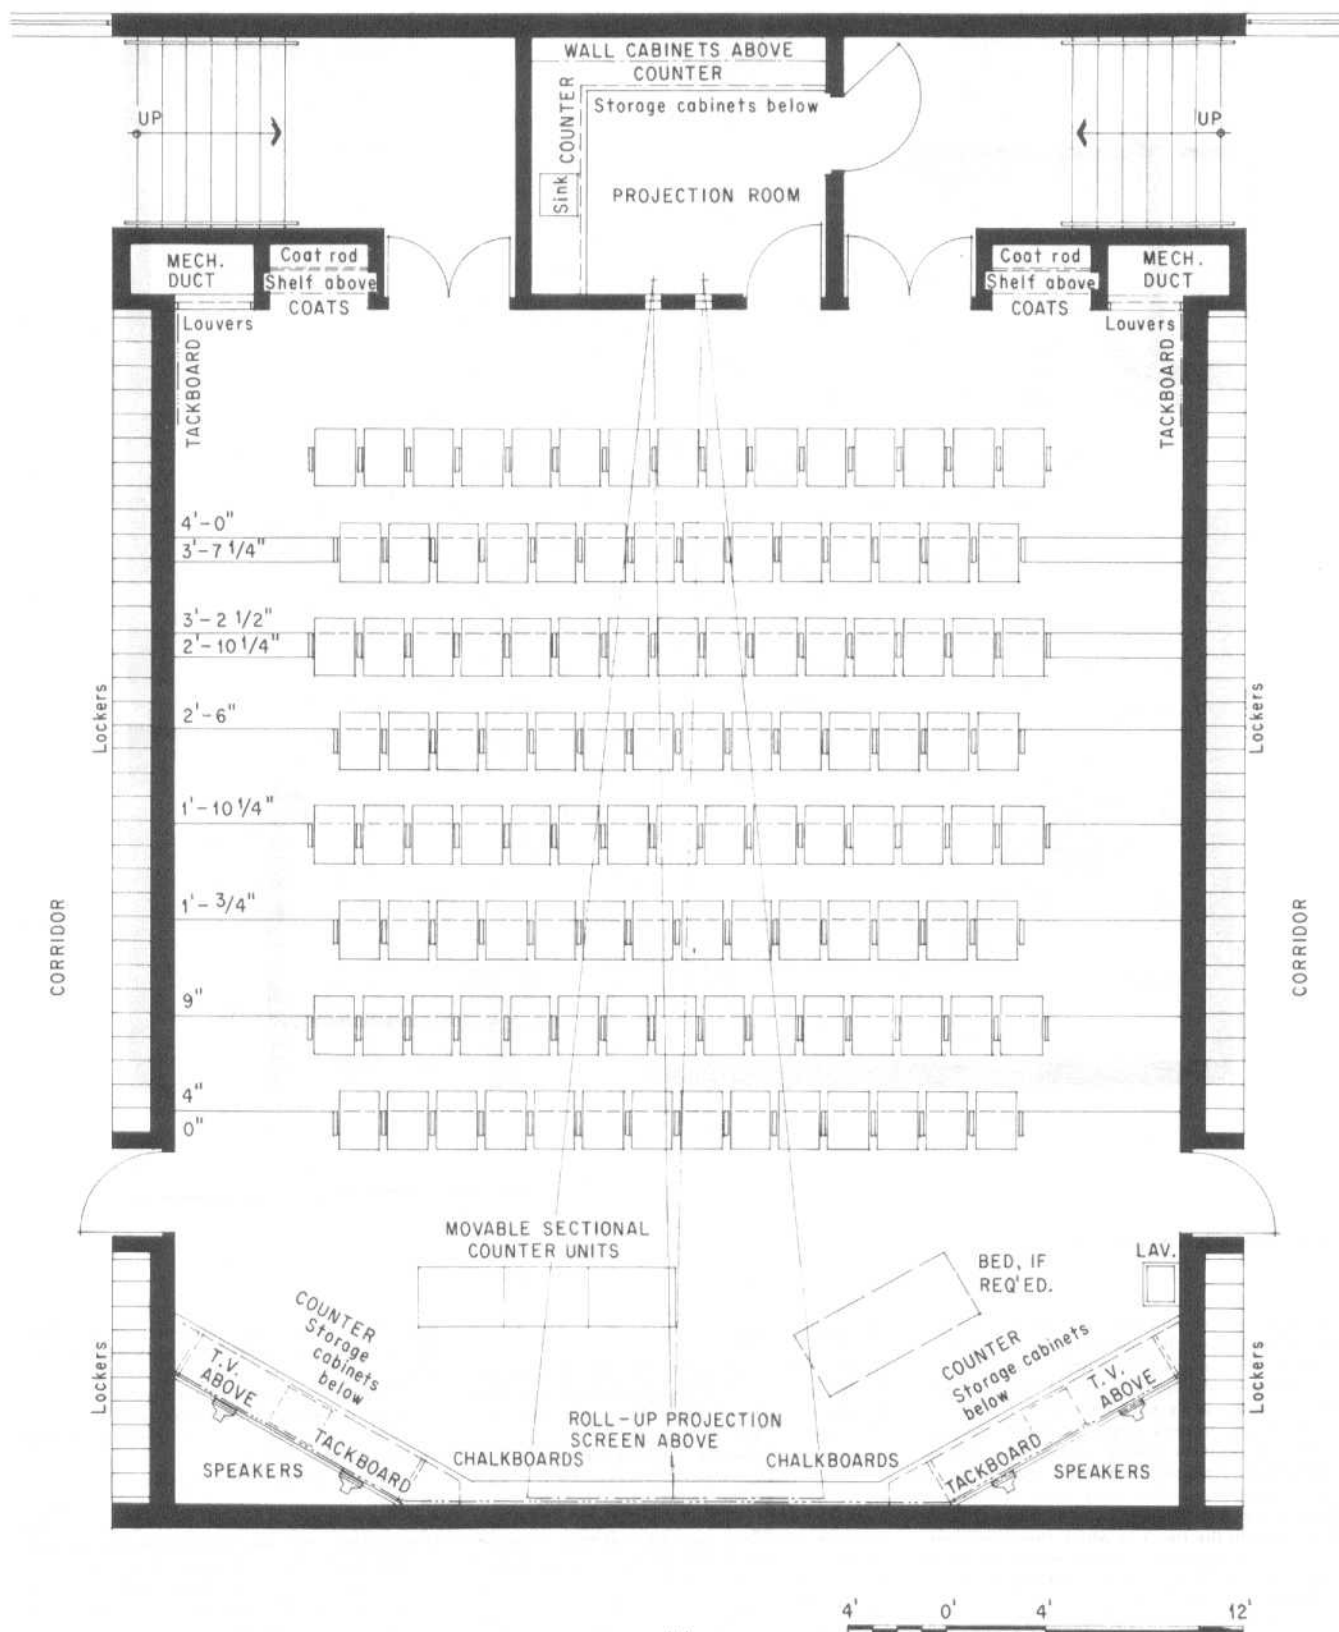

Fig. 6 (cont.) Lecture-demonstration rooms.

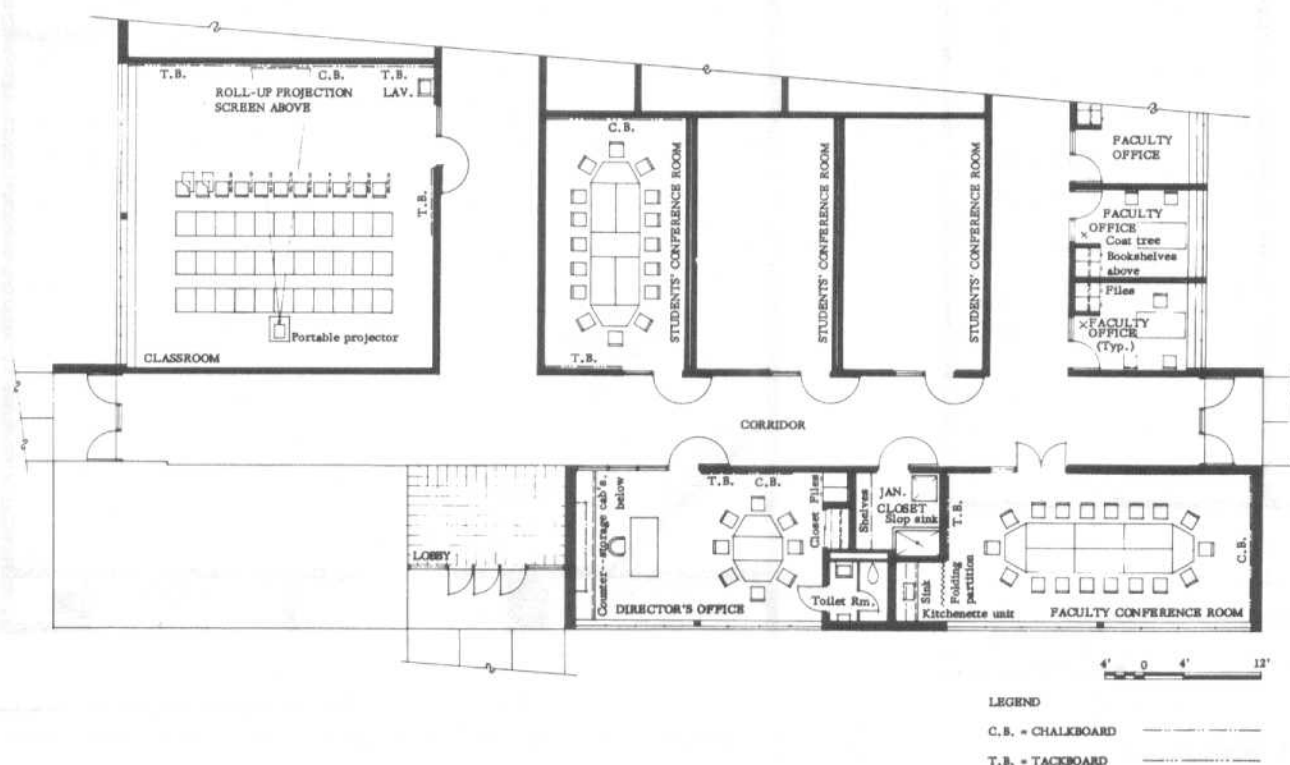

Fig. 7 Student-faculty areas.

NURSING SCHOOLS

Design factors to be considered for these laboratories are:

- Counters of different heights with knee space underneath and reagent shelf. These may be located along the walls or, if the space permits, an island-type counter similar to others should be provided.

- Chemical-resistant sinks with hot and cold water.

- Gas, air, and electrical outlets.

- Fume hoods with adequate exhaust system and sprinkler heads.

- A refrigerator or freezer may be needed for these laboratories.

It is assumed that the animals needed for research will be supplied from a central location, since it would not be economically feasible to construct special animal housing facilities within the nursing education unit.

Behavioral Science Laboratory The primary requirement in the behavioral science laboratory is that the human subject be observed unobtrusively by the students. (See Fig. 12.) Thus, the following design factors should be considered:

1. The laboratory should be large enough to accommodate a bed and various patient care activities. Space is also needed for research personnel and equipment.

2. An adjacent observation room with a one-way viewing glass partition will provide an overall view of the laboratory. The one-way viewing glass partition should be double glazed with sealed airspace between the glass to ensure sound isolation between the two rooms. The viewing screen should be unobtrusive floor-to-ceiling panels rather than a view window which in itself may suggest its purpose. Not all panels need be two-way glass—only those necessary for viewing.

3. The observation room should accommodate 16 students. A stepped seating platform, either permanent or temporary, might be considered to assure all the participants a good overall view of activities within the laboratory. Since the subject should not be disturbed while being observed, observation rooms should be carpeted and should have sound-absorbing materials on walls and ceilings.

4. Provision should be made for communication facilities between the two rooms as well as for concealed recording and audio and physiological factor monitoring equipment.

5. Both the behavioral science laboratory room and the observation room should be equipped with a dimmer switch to control the illumination level. Temperature and humidity controls are also important.

6. Facilities which should be directly accessible from the behavioral science laboratory include:

- Toilet room with lavatory for hand-washing
- Kitchenette or alcove with kitchen accommodations

- Storage room for storing equipment such as children's toys

In conjunction with behavioral science lab-

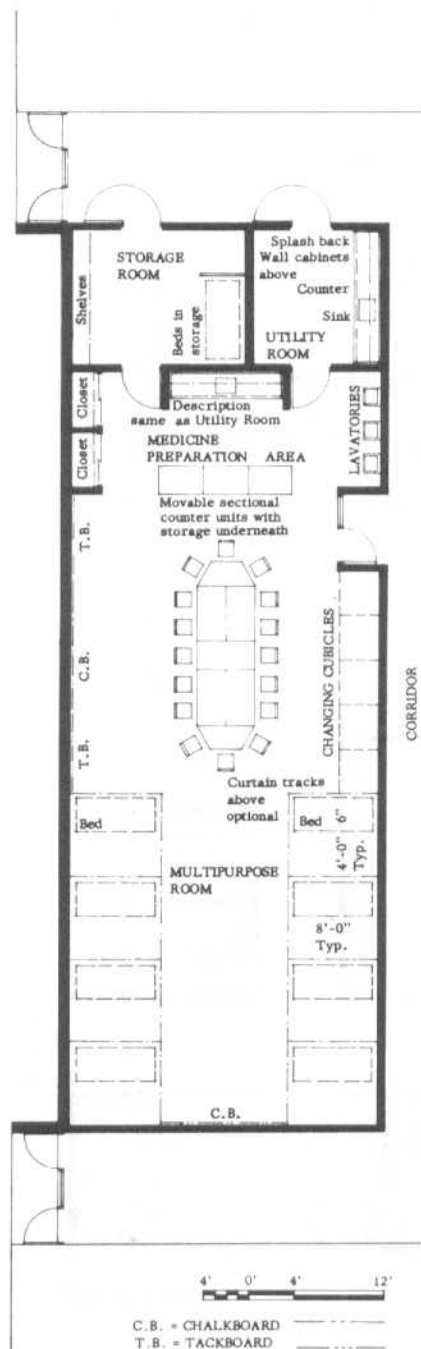

Fig. 8 Multipurpose room.

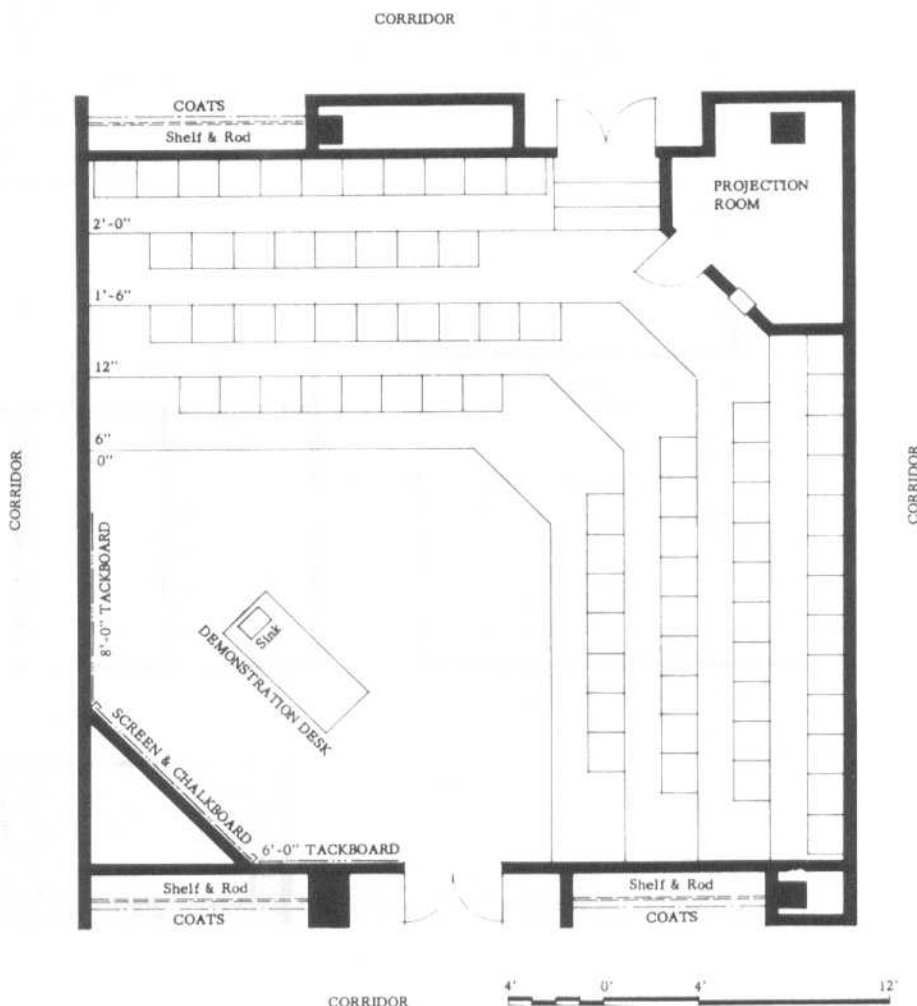

Fig. 9 Lecture-demonstration room at Texas Woman's University College of Nursing, Houston, Texas. (Freeman and Van Ness, Architects.)

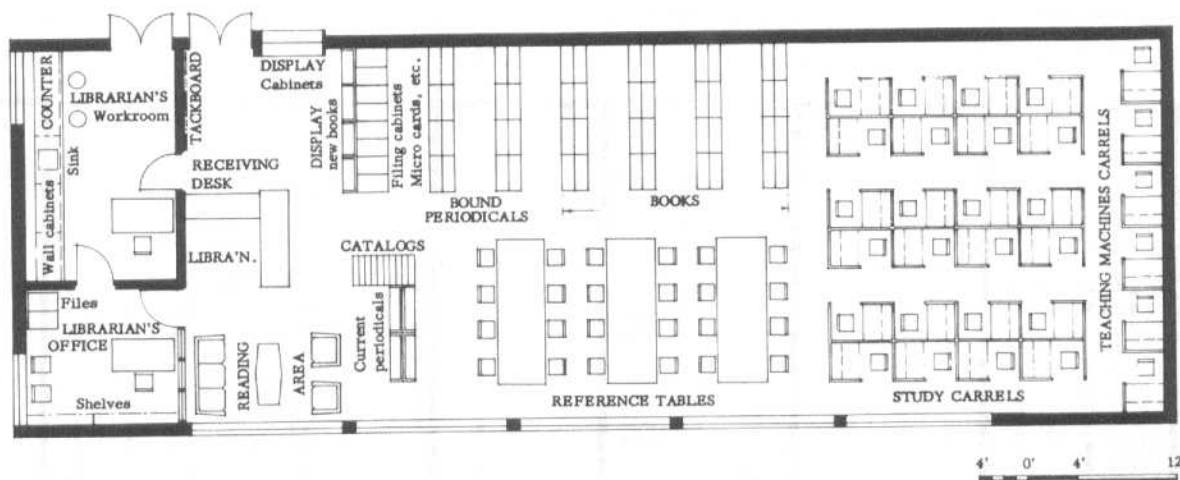

Fig. 10 Library facilities for a diploma nursing program.

oratories, the following should be considered:

1. Waiting room or area, suitably furnished for adults or adults with children.
2. Play nursery for children with provision to oversee the activities from the waiting room. Special attention should be paid to acoustical treatment of this room and its decor.
3. Interviewing rooms, with adjacent observation room, separated by one-way glass viewing partition. (Items 2-5 cited above also apply here.)

Faculty Offices

Faculty offices may be grouped together to form the faculty offices suite. In programs having a small faculty, administrative and business offices may be grouped together with faculty offices forming a unit that is separate in character from the teaching spaces. (See Fig. 7.) In addition to offices for each faculty member, one or more offices might be provided for guest lecturers or visiting faculty.

The faculty offices suite should include:

- Individual offices for each faculty member. Each office should have ample space for furniture, bookcases or shelves, and files.
- Conference room or rooms. The size of the conference room depends on the number of people to be accommodated. Chalkboards and tack boards are necessary in these rooms.
- Faculty lounge. An alcove or small room off the lounge may be provided to accommodate a kitchenette unit and a counter with sink and storage cabinets underneath.
- Toilet facilities including a washroom and locker room or lockers, located in proximity to the lounge or adjoining it. An alcove off the washroom or small room accommodating a sofa, cot, or other suitable furniture might be considered.
- Graduate assistants' office. This room should be furnished with desks for use of teaching assistants or graduate assistants.

In addition to the teaching machines located elsewhere in the school for students' use, some teaching machines may be needed in the faculty office suite for use by members of the faculty who may be engaged in developing programed materials.

Data Analysis Room The data analysis room will require space for calculating machines, tables, and office-type furniture. Area allocation should be made for storing data. Other requirements include individual offices and a conference room that can be used by research personnel.

Offices and Ancillary Supporting Areas Requirements for office space and for supporting areas and services will vary from school to school. Each program, therefore, should determine its particular needs. Some of the spaces to be considered include:

1. A lobby and reception area with an information desk as a point of control. The information desk or counter may be incorporated in the general office. In small schools the lobby or reception area may also be the secretary's office and the secretary may also be the receptionist. Toilet facilities for visitors should be conveniently located.
2. General office including space for secretarial staff. The amount of space needed will be based on the ratio of secretaries to faculty members established by the school's policy.
3. Space for filing cabinets for the students' active records. This may be either a part of the general office or a small room directly accessible from the general office. A storage area should be provided for inactive files. Programs organized under hospital control must provide space for permanent storage of student and school records.
4. Space for duplicating equipment including a counter with sink and storage cabinets underneath. This space may be either an alcove in the general office or a small room directly accessible from the general office.
5. Storage room for stationery directly accessible from the general office.
6. Small room for receiving, dispatching, and distributing mail and packages. This room also may serve as a message center for faculty members.
7. An intercommunication control system (switchboard) within the general office. Intercommunication between the rooms within the facility for nursing education is highly desirable. Outside calls should be handled by one

person who would transfer them to the party concerned or, when necessary, take messages.

8. Wall space should be allocated for official bulletin boards either in the lobby waiting area or outside the general office.

9. Storage room for miscellaneous office equipment or furniture.

10. An office for the dean or director. The office should be large enough to accommodate several people for small conferences. A private toilet room with handwashing facilities and a coat closet adjacent to this office is highly desirable. (See Fig. 7.)

11. An office for a secretary adjoining or accessible to the office of the dean or director.

12. Office or offices for assistants or associates of the dean or director. These offices should either be adjacent or in proximity to the office of the dean or director.

13. Office for registrar with ample space for filing cabinets.

14. Office for admissions officer with ample space for filing cabinets.

15. Students' health service and observation area.

16. Office for students' counselor, incorporating waiting area.

17. Office for graduate assistants and fellows, each of whom should have a desk.

18. Janitors' closets and storage space of housekeeping supplies.

Students' Facilities

Provision of student facilities should be governed by such factors as enrollment and the school's physical setting. Whether the facility is a self-contained unit or is a part of a larger education complex is an important consideration. The needs should be evaluated and established individually for each program.

Spaces for the following should be considered:

- Toilet room and washroom for women students with adjoining room or alcove to accommodate a sofa or cot.
- Toilet room and washroom for male students, if any.
- Locker rooms or lockers in corridors.
- A student lounge may be found desirable.

Fig. 11 Typical research laboratory arrangements.

Fig. 12 Behavioral science laboratory for a nursing graduate program.

particularly if no other lounges in the facility are available to nursing students. A lounge may be provided in the students' residence, which may be physically connected with the nursing education facility. In some facilities, students' lounge or lounges are provided, either in the student union building or elsewhere on the college or university campus.

Supporting Areas

Listed below are planning considerations for supporting areas:

- The provision of coat alcoves in corridors may be desirable.
- The need for general storage rooms should be determined by each program.

- Housekeeping and maintenance rooms, including janitors' closets and storage areas for housekeeping supplies and equipment, will be needed.

- Space should be allocated for vending machines either in alcoves of corridor or centralized in one room assigned for this purpose.

- An adequate number of public pay telephone booths should be located in strategic locations in alcoves off corridors so that traffic will not be obstructed.

- An adequate number of drinking fountains or water coolers should be placed in alcoves off corridors or recessed in the wall so that traffic flow will not be obstructed.

Continuing Education

Continuing education is usually a part of the overall school facility. However, for the purposes of nursing education, it would have the following elements:

- Assembly room to seat a large group
- Conference rooms
- Lounge room and space for coffee service
- Reception and registration area
- Men's and women's toilets
- If warranted, offices for the continuing education director and staff

Assembly Room The number of people to be accommodated in the assembly room will depend upon the individual facility. In general, provision should be made for 100 or more persons, seated along rows of tables or groups of sectional tables. A movable platform to elevate the speaker should be considered.

If found desirable, this room may be subdivided into from two to four conference spaces by means of folding partitions which should preferably stack up in a wall alcove designed for this purpose. They should be selected for maximum sound-retardant properties to limit the passage of sound from one space to the other. Sound reduction of at least 25 to 30 decibels is considered minimum. These conference spaces should have chalkboards and tack boards.

Conference Rooms In some institutions it may be desirable not to subdivide the assembly room, in which case four or five small conference-type rooms should be provided, each to accommodate from 20 to 25 persons. These rooms should have separate entrances, should be equipped with chalkboards and tack boards, and should be arranged with seats around tables for face-to-face conferences.

Reception and Registration Area Definite allocation for the reception and registration area should be made. Coat room or alcove for depositing the outer garments should be incorporated.

Lounge Room. A lounge room should be provided large enough to accommodate the anticipated number of participants in the Continuing Education Program. An alcove accommodating a kitchenette unit, counter for coffee service, and vending machines may be considered desirable.

An adequate number of toilets should be convenient to this area.

YOUTH TREATMENT CENTERS

By Kenneth Ricci, Architect

BACKGROUND

The residential treatment concept has its foundation in the *halfway house* program originally developed for men returning from prison to the outside world. Residence in the halfway house, as its name implies, was an intermediate stage between prison and freedom, during which the ex-convict could readjust to normal responsibilities, look for a job, and resume an independent life, all within the security of the house. It was a temporary situation providing bed, board, advice, and company. From the halfway house the newly freed man was expected to begin an independent, constructive life.

The basic attribute of the halfway house was that it provided independence within a framework of emotional and financial security. The house was used for adults as well as juvenile ex-offenders. Perhaps the most famous house for adolescents is the Highfields House, established in New Jersey in 1948. Highfields was the model for virtually all the initial juvenile halfway houses. The concept has spread widely because of its humane approach and its recorded successes, until presently the residential treatment concept is being used for narcotics treatment, youth offenders, probation cases, and social service shelters.

Unlike the original halfway house, which was a way station between prison and the outside, the residential treatment centers presently are operated for ex-offenders as well as for those with no criminal conviction who are referred to the program. The efficacy of this approach is considered to lie in the residential, as opposed to the institutional, character of the facility—maximum size is usually between 25 and 30—and in the *treatment* of residents rather than their punishment or neglect.

TARGET POPULATION

Community-based residential treatment centers are now being operated for a variety of programs. Correction, narcotics, and probation agencies now include residential, neighborhood-based programs as part of their treatment spectrum. Youth agencies, on both municipal and state levels, operate programs for adjudicated youths as well as youths referred from family court as a condition of probation or referred from public or private agencies with parental consent.

Private agencies also operate residential facilities for young people referred from their family counseling bureaus with attitudinal or behavioral problems. Among private drug treatment programs, the "house" concept is widely used, with many variations ranging from in-city programs to monastic retreats.

Whatever the program, the target population includes those young people who express a desire to improve their life; those who can relate to people—adults, peers—either negatively or positively, but who are willing to deal with others; those who can recall their past and are willing to discuss it; those first offenders who

would be brutalized by a large institution or even those who are not convicted of crime but need a release from pressures in the home environment.

GOALS

The basic goal of this type of program is *treatment*, rather than punishment, for antisocial behavior. Other goals usually are *control* of activity within the facility and in the immediate neighborhood, *services* for the residents (i.e., medical, educational, employment, recreation), and proper *administration* of the total program.

The purpose of this report is not to delve into the conceptual foundations too deeply, especially since these vary from agency to agency, but to set forth some general goals and examine how these can be translated into an architectural approach (see "Architectural Considerations," below).

Treatment in these centers is currently focused on peer group interaction. Through the use of pressure from peers in group therapy

sessions, individuals are forced to deal with their behavior, its motives, and its consequences. These therapy groups, with no more than 10 to 12 members, are led by staff members. Ideally, members of the group should share living and sleeping areas in the program. This becomes an important design concern. Individual *counseling* is also done by various staff members, from ex-residents through psychiatrists. An important aspect of treatment comes through coping with the simple routine of daily living with peers, neighbors, employers, teachers, and staff. Exposure to nonprofessional staff, like the woman cook or custodian, provides important links to parental or big-brother figures. Often the cook is the only woman accessible to the young resident in the facility.

Control in the residential center is not applied as it is in the prison, with walls and barriers, but instead it is implied through behavior standards set by the staff and peer group. In this way, self-control will hopefully become internalized and remain active while the resident is out of the facility and especially

Illustrative Area Requirements

(Typical Program for 21-bed unit—intended only as a guide)

Space	Area, sq ft	Remarks
Administration:		
Director's office	175	
Secretary, reception, files	200	Preferably near entry for control.
Assistant director	150	
Interview offices, 2, at 100 sq ft each	200	For private interviews between resident and caseworker.
Kitchen	350	
Food storage, garbage room, and receiving room	250	Depends on purchasing patterns and delivery schedule of supplies.
Dining room (capacity: 30)	600	Family-style service. No serving counter. Staff and residents share dining room.
Lounge	600	Quiet activities.
Recreation	600	Active activities.
Public toilet	As required	Men's and women's lavatories accessible to above spaces.
Bedrooms, 21 at 100 sq ft each	2,100	
Residents baths	As required	5 W.C., 5 lavatories, 5 tubs or showers.
Counselor's bedrooms, 2, at 150 sq ft each	300	
Laundry room	As required	
Linen storage	As required	
Director's apartment	1,500	Should have private entrance.
Net total	7,025	
Gross total*	10,725	

*Gross = 1.5 net; includes mechanical equipment space, corridors and stairs, toilets and baths, janitor's closet, custodian's room, construction thickness.

YOUTH TREATMENT CENTERS

after he has left the program. Of course, audio and visual control are necessary for general security. Ease of supervision should be built into the building so that staff can generally see and hear what is happening without deliberate snooping.

Access is usually through only one door, and this will have to be controlled in order to keep track of who comes and goes. Electrical security devices include remote sensors for doors, closed-circuit television, smoke detectors, etc. These devices are used only with utmost discretion, especially the television eye, since they could seriously compromise the treatment approach.

Services such as medical care, education, employment, and recreation may be supplied by the facility but should ideally be accessible in the community. Since most programs stress learning to adjust to "real life," education, recreation, and employment in the neighborhood are encouraged. Larger facilities may have to provide these services; the more community services are available, of course, the more economical and effective the smaller program will be, insofar as it simulates home environment.

Administration varies according to the facility. Basic staff usually includes a director, assistant director, secretary, live-in counselors, visiting counselors, and cook. According to the type of program, teachers, social workers, and work supervisors may be included as optional. Since therapy groups include all or half of the residents, they are usually run by the director or his assistant with the aid of the counselors. This minimizes staff numbers and maximizes interaction.

Quarters are often provided within the facility for the director and/or assistant director (sometimes including family) as well as the live-in counselors. The director's quarters ought to be distinctly separate but adjacent; live-in counselors reside within the facility, adjacent to their respective groups. Live-in directors are a departure from institutional precedents but are quite frequent in this type of program. When staff and residents live together, confidence and stability are encouraged. The architect should keep in mind the privacy requirements of the family in residence. Since programs are located in a community, isolation of the live-in family is less a problem than it would be on the grounds of an institution.

With regard to the tabulated area requirements, it should be noted that

- Twenty-one beds is an arbitrary size, used here for illustration only. Any program with a few less residents will not efficiently utilize the facilities listed; any program with a larger number of residents might lose the residential quality. Numbers will vary from agency to agency, but rule of thumb puts optimum size between 21 and 30. The total population should ideally be a multiple of a therapy group.

- Making efficient use of administrative staff while maximizing residential milieu is the rationale for the seven-bed-unit approach. Three physically separate seven-bed units are each run by a pair of houseparents, all under the supervision of one administrator. Neighborhoods apparently accept seven more readily than twenty or thirty new young residents, especially since seven youths plus two houseparents can move right into an existing two-family home. Renting the home keeps it on the tax rolls. One seven-bed unit was set up in an apartment in a New York City housing project. The seven-bed unit operates like a private household and has just about the same type

of residential requirements that a family of nine has.

- Certain spaces, like lounge or recreation spaces, can be made accessible to community groups for their use. These spaces should have access directly from entry and should adjoin public toilets. Directors like to make their facilities available to neighbors in order to build good relations.

- The irreducible design element in this type of program is the therapy group. The residents who share the same group therapy sessions are usually grouped together in sleeping areas, so that throughout the design the group's size and integrity ought to be reflected in the layout of the various spaces.

SITE SELECTION

The entire concept of community-based residential treatment hinges on the location of the facility in a neighborhood setting similar to that to which the resident will return.

Each locale will have different criteria for site selection. Each will have specific problems. The most common problems are zoning restriction, building code restrictions, and the opposition of local residents. Local resistance can be quite intense initially; one architectural reaction to this problem is to purchase and renovate an existing building in order to keep low visibility. For such purposes programs should be kept to smallest size feasible (see table, above, showing area requirements), like the seven-bed unit. Leasing a building keeps it on the tax rolls. Renovation can be a trap if the building is not sound; examine foundations and floors, and especially plumbing, electrical wiring, and heating. Client's patience can be worn very thin and extras can mount on a bad choice. (See "Special Considerations" below.)

Programs should be near transportation to schools, jobs, recreation. The more outside services are accessible to the residents, the

less services the program itself needs to provide. Likewise, proximity to transportation will make it easier to attract staff personnel and for visitors, family, university consultants, etc., to reach the program. On-site parking spaces may be compulsory in some suburban neighborhoods.

Where conditions permit, an outside recreation area is desirable. In the urban facility, the rooftop of a new building can be made to fill this function provided that it meets local codes. Too much land around a program can, however, isolate it from the community and reinforce an institutional attitude on the part of residents and staff. The spatial distance between community and facility can often be overcome by mechanical means; the social distance between the two must be overcome by staff and residents in order to allow the program to bear fruit. Making spaces available to local groups, for example, decreases the social distance between home and neighborhood. Proper site selection can accomplish much in reducing social distances.

ARCHITECTURAL CONSIDERATIONS

This discussion of some typical areas of the building designed is intended to be illustrative, not definitive. It gives an indication of the various interwoven considerations—economic, behavioral, administrative—that play upon the design process.

Territory and Status

For the architect, two key conceptual tools in arranging spaces in a facility like this are *territory* and *status*. The provision of clearly defined territorial boundaries—private, semi-public, public—in institutional situations is an aid to residents in guiding themselves and their actions. Certainly territory—one's room, one's den—is at issue even within a family, and still more so in a program, regardless how intimate

Fig. 1 Kitchen planning concepts in a suburban residence.

In this enlarged plan of a kitchen it can be seen that location near the entry yields several benefits: the cook has full-time view of entry and parking lot; ease of deliveries; interaction of woman cook with boys—boys do chores in return for snacks and recognition. Visual control: view of parking and entry. Aural control: vending machine noise, door hinges tell of activity at door. Interpersonal control: most boys use entry at kitchen side while staff and secretaries use entry at office side. Kitchen has more action, more status, more snacks.

YOUTH TREATMENT CENTERS

or small-scale. As intimacy and trust increase, the pressure to defend territory seems to decrease. That is the point when some programs remove locks from personal belongings—to test out the group's attitudes.

Likewise by sharing territory, one shares an extension of oneself. When the cook asks residents to help, to do favors, run errands, she returns the favor by sharing her territory—her status—with the youngsters. By the same token, some spaces have no status. The notoriously empty "lounges" in some facilities bear witness to this, while young people crowd into the room of a favorite counselor. The spaces in these cases have a certain value because of the status of their inhabitants, while other spaces have little or no status. In so intensely social a situation as the residential center, the design of spaces must be modulated by acute behavioral considerations such as territory and status. Each person ought to be able to easily identify his territory—room and belongings, office or kitchen—while at the same time he should be able to share all or part of it with another. This goes for both staff and residents. Often staff use their authority to control or lock off certain spaces, and in the process they convey the sense of dominance so often associated with institutions. The architect cannot control the inhabitants, but he can make himself aware of the issues and learn to modulate the design of space to account for their relation to behavior. These concepts—territory and status—are only two among many. Further reference vectors are found in "Information Resources," below.

Kitchen

In the smallest facilities (seven-bed), the kitchen is simply residential in design. Since program sizes vary, it is not constructive to enumerate kitchen equipment or kitchen area. General performance criteria for kitchens are as follows:

- Residents almost universally help in the kitchen. This is part of the responsibility of all residents to lend support to the house. All equipment, furnishings, and detail should therefore be of extra heavy-duty construction since it will be exposed to hard and inexperienced personnel. A safe and easily maintained design could have tiled surfaces, floor drains, and metal pan ceilings for fire retardance, washability, and sound dampening.
- Relation to dining room can be informal, since family-style service is often used.
- The cook, often the one accessible woman in the facility, should not be isolated by the kitchen design. The kitchen should be, if not central, at least conveniently located in regard to the common and entry areas.
- In smaller programs the kitchen can be designed as a control point near the main entry in order to capitalize on the full-time presence of the cook during the day. This is economically wise from the staffing viewpoint. Young people will gravitate toward the kitchen for available snacks. Figure 1 illustrates a kitchen serving several goals in a 20-bed program: food preparation, entry supervision, and interaction of boys and cook.

Bedrooms

- Single room occupancy is usually preferred in these programs. For many residents this will be the first time that they have had a private room, private territory, of their own. For economy, bedroom sizes are usually minimal. While the value of privacy is considered

Fig. 2 Schematic plan—basement.

The basement lets out onto the open yard. Dining, recreation, and circulation connect with the outdoors. Kitchen connects to the street side. Open stairwell communicates sights and sounds to the first floor.

Fig. 3 Schematic plan—first floor.

The first floor is the hub. Use of the lounge by local folks can reduce social distance between program and community, so it is placed near entry and toilets. Office near entry has a view of inside and outside, of upstairs and downstairs. The eye and the ear replace the foot for control.

YOUTH TREATMENT CENTERS

great, it is important to arrange the individual rooms so that the resident cannot deliberately isolate himself from the activities of the program.

Dormitories and four-man rooms are often used, while two-man rooms are often discouraged because of aggression, turnover rates, and homosexuality. In the dormitory situation, the strains of daily communal living are multiplied. The supply of private "territory" is at a minimum and constantly subject to aggression, theft, damage, etc. In dormitory design, therefore, it is important to give thought to provision of easily identified and defensible territory in the form of furniture, storage, shelving, bed, textured or colored floor surface or changes in floor levels, ceiling heights, etc. (see Furnishings, below). For most residents, their sleeping area and belongings constitute their entire worldly possessions; therefore the maintenance of these becomes very important. The diagram (Fig. 5) indicates an approach to creating an immediate private zone around the bed, providing easily defined space and lockability and meeting personal storage needs.

Control

Residential, community-based programs usually require no overt physical constraints on residents. No walls. No locked doors. Instead of physical control, these programs aim initially at developing a sensitivity to social control in youths and ultimately at a sense of self-control. The mechanisms for creating these internal controls are group therapy sessions, individual counseling, exposure to community living from a stable, supportive residential base, and a frankness and intimacy among staff and residents. In short, the aim is to simulate a domestic environment with responsibilities shared by youths and staff. For this reason, residents must help in the kitchen, residents and staff eat together, and staff lives on the premises (with family or without).

Physical controls in the traditional sense are usually not used. Nevertheless, a certain measure of supervision by the staff must be pos-

sible, just as a well-designed house enables a mother to keep track of her children, either indoors or out. The architect has at his disposal three unobtrusive supervision methods: aural, visual, and movement supervision. The relation of corridors, windows, and key rooms like kitchen and offices, will enable staff persons to hear if not see the activity of the house. Open stairwells (building codes permitting) and courtyards carry sounds. Sounds carry messages. By locating vending machines properly, the cook in the illustrated kitchen (Fig. 1) can keep track of activity near the door. Visual supervision is the most difficult to achieve without resorting to long corridors, view panels on bedroom doors, etc. By using hard materials in key areas, sounds can be reinforced and transmitted. The control of movement through architectural design can enhance supervision. Judicious placement of entry, kitchen, and lounges—the natural gravitation points of hungry teen-agers—can ensure a view of moving people by staff. A window overlooking a parking lot or an office by a stairway are effective means of supervision in a small center. See accompanying diagrams (Figs. 2, 3, and 4).

SPECIAL CONSIDERATIONS

Renovations

Renovations are attractive to many agencies because of the public pressure for action and the budget restrictions on capital construction. When operating with a tight schedule or a tight-fisted comptroller, the lure of renovation is strong. Under such conditions, renovation should not be extensive. Mechanical, electrical, and plumbing facilities should be in good enough condition to remain, otherwise cutting and patching for a new system will drive up the cost. Extensive renovation is exceedingly time-consuming and contractors competent in such work are scarce and expensive. The only reason to consider renovation on a large scale would be if the building has special historic or esthetic value to the community or the program.

While the cost per square foot of major renovation can be 20 to 30 percent less than new construction, a well-planned new facility often needs less square feet than an existing building. Ultimately the total costs of renovation and new construction will not be far apart. As a rule of thumb, say that if renovation cost is 75 percent or more of comparable new construction, new construction is preferable since it can be completed faster, will have less contingency costs, and can be designed much more efficiently.

Mechanical Equipment (H.V.A.C., electrical, plumbing, elevators) Saving existing equipment may be false economy for two reasons. First, it may inhibit efficient, effective planning. Second, the original equipment may be faulty. Check existing maintenance and expense record if available; this will give an inkling as to past performance. Installing new mechanical equipment in an existing structure is costlier than installation in a new structure; add 15 percent of equipment cost for cutting and patching.

Code Checklist When considering the renovation potential of an existing building, some basic factors ought to be considered.

a. Multiple dwelling codes and/or social service regulations may place restrictions on the number of occupants per room, regardless of room size. Check applicable codes to determine the building's capacity for sleep-in occupants.

b. The required fire protection devices (alarms, smoke or thermal detectors, sprinkler systems) are based on the construction classification of the building; its area and height; and the number, age, and physical condition of its residents. When considering renovation, check the area, height, and construction class of your building against the fire protection requirements of the building code as well as municipal or state social service regulations. Fire protection regulations for public agencies are strict even when there are as few as seven or nine residents in a standard residential dwelling; certainly they are far stricter than requirements for one-family dwellings.

A new water service and sprinkler systems can be expensive in urban areas. Additional expenditures for a pump to provide adequate water pressure may be needed. In some areas, a water meter must be attached to the sprinkler system by law.

c. Egress requirements are usually stringent. The entire building (especially if multi-storied) should have two means of egress via fire-rated corridors and openings. Assembly areas (dining, auditorium, lecture) should also have direct, unobstructed egress. One egress may be acceptable if protected by sprinklers, smoke or heat detector, and alarm system.

d. Local fire departments may also have rules calling for special equipment for group occupancy structures: smoke detectors, alarm systems, fire extinguishers, and perhaps persons trained in emergency techniques.

e. Rooftop areas, especially in urban sites, often have the potential for excellent recreation areas when proper protection, egress, and area requirements are met. Rooftops may require separate certificate of occupancy.

f. Floors should be capable of carrying the large live loads required for assembly areas (dining, auditorium, recreation, corridor). It is often difficult to prove live load capacity to a building department if the original plans of an old building are lacking. Replacing existing floors with capable floors is tricky and expensive.

Fig. 4 Schematic plan—bedroom floor.

The concept illustrates a group of private areas or rooms around a common territory, the open yard. Open stairwell gives a view down each corridor. A counselor lives on each floor. The plan is open, yet each territory is defined.

YOUTH TREATMENT CENTERS

(a)

(b)

private semi-private private

private semi-private private

(c)

Building Codes These can be flexible. If a particular building is well suited to your needs and yet cannot be made to comply with local codes in certain categories, a reconsideration may be requested based on need and on a willingness to provide extra safeguards or concessions in other categories of the code.

Leasing

The leasing of small, sound residences ready for immediate occupancy has been done for seven-bed units. This is the quickest and least obtrusive means of filling the architectural needs of a program, since the houseparents and residents move right in without disturbing the physiognomy of the neighborhood. The decision to lease or buy will be made according to the agency's financial policy. Leasing keeps the property on the local tax rolls; this can be a benefit when developing rapport with the community. The relatively modest investment in such a situation gives the agency great freedom to cope with a changing neighborhood, changing treatment concepts, or budget fluctuations by returning the lease or allowing it to lapse when the facility is no longer viable.

CONSTRUCTION, FURNISHINGS, AND SPECIAL EQUIPMENT

Construction

• Generally, surfaces should be finished to provide ease of cleaning or painting, resistance to heavy wear and defacement, fire retardance, and noise dampening. The general starkness of such surfaces in bedrooms, corridors, stair halls, etc., can be relieved with use of chromatic colors and, in the lounge areas (for example), by use of carpet on floors and walls. Youngsters usually respond to unusual textures and strong colors. Administrators usually

shown in open position

shown in closed position

(d)

Fig. 5 Graphic concepts of territory in group living.

(a) Undefined territories. Definition of territory varies from occupant to occupant, depending on his status within the peer group. (b) Defined territories. Definition of public, semi-private, and private areas is accomplished by using architectural elements. Therefore, size and shape of private territory are not dependent on individual's status. Private areas can be defined as zones within a dormitory or as individual rooms along a corridor. See accompanying diagrams. (c) Dormitory with defined territories. Bed and lockable storage units (see enlarged sketch) form private territory zones along semi-private walkway. Walkway can be defined by using space texture, color. (d) Private territory.

YOUTH TREATMENT CENTERS

do not. Sound dampening increases the intimacy of a room and lessens the institutional feeling.

- *Glass areas* should be kept small; large areas ought to be tempered or wireglass. Window dimensions—opening size, height above finished floor—should reflect the more intimate scale required for children in a domestic setting.

- *Hardware.* The open nature of residential treatment usually calls for nothing more than a sturdy grade of domestic hardware. This will depend on the program director. All individual bedrooms and offices should have key locks; provide a master key for staff personnel. Bathroom privacy is kept intact normally, with doors on all toilet stalls.

Furnishings

Domestic furniture, sturdy, ample, and colorful, fills the bill for most areas, including dining, lounge, and group rooms. Bedrooms are discussed below. In many programs residents build their own furniture as an economy measure. Some administrators believe that residents take better care of such furniture and equipment than of ordinary institutional furniture. Administrative areas require file cabinets, typing desks, etc., all of which should fit into the domestic scale.

Individual Bedrooms These should have a writing and reading surface, clothing storage (hanging and folded), suitcase storage, seating for two or three, and a single bed. Storage areas should have key locks, as should the room doors. Seating and storage might be built in and/or incorporated in the architecture (a window seat, for example). Ample tack board and shelves should be provided for pinups, posters, etc. For many residents, especially young people, this will probably be the first time they have had a private room; the room is considered an individual's "territory" and as such should be susceptible to some rearrangement according to his/her idiosyncrasies—often the arrangement of a room will give the staff an indication of the occupant's character.

Group Bedrooms or Dormitories These should provide the same basic "territorial" needs as the private rooms: sleeping, sitting, writing/reading, locked storage, display surfaces (tack board, shelves). The necessity for easily identified and defensible territory is acute in institutional programs, especially in communal living arrangements, since there is less privacy in these circumstances. Conflict between residents is lessened when personal belongings can be securely stored. Some programs remove locks when they feel that intragroup trust has been built up. The architectural solution to this territorial question has an important impact on group living. In a dormitory situation, compact, foldaway territory provides one type of solution. See Fig. 5.

Special Equipment (Optional)

- Intercom between staff areas
- Emergency lighting and power system
- Central smoke detection system and/or fire alarm system

- Closed circuit television and videotape facility for group therapy sessions
- Master antenna system
- Elevator
- Garbage disposal or condenser

INFORMATION RESOURCES

Agencies

The following agencies either operate community-based, residential treatment centers themselves or advise on and regulate the operation of such centers. Contact agencies of a similar nature in your area for material, permission to visit, and interviews with staff and administration. Most programs are quite enthusiastic about visitors. Those listed are intended only as examples of such agencies. The persons named are those with whom the author has been in communication.

New York

New York State Division for Youth
2 University Place
Albany, N.Y. 12205

Operates rural and urban programs ranging from 7-bed units to 60-bed camps.

New York State Department of Social Services
1450 Western Avenue
Albany, N.Y. 12203

Responsible for designing and operating public programs and for regulating and licensing private programs of various sizes.

California

State of California
Department of Corrections
California Rehabilitation Center
P.O. Box 841
Corona, Calif. 91720

Operates many treatment modalities within a large compound and has experimented with concepts in innovative institutional living.

Florida

State of Florida Division of Youth Services
311 South Calhoun
Tallahassee, Fla. 32304

Operates youth programs on a residential scale at several urban and suburban locations and is expanding these facilities rapidly.

Ohio

International Halfway House Association
2316 Aubercroft
Cincinnati, Ohio 45219

Organization representing halfway houses of many modalities, run for many types of individuals by both public and private agencies. A good central source for locating programs in practically all the states of the Union.

Federal

National Clearinghouse for Criminal Justice and Planning
Department of Architecture
University of Illinois
1102 W. Main St.
Urbana, Ill. 61801

National Institute sponsors inventories of current correctional programs, research into correctional modes, and demonstration projects. Contact the Institute for list of projects and publications.

Publications

Most agencies produce many unpublished but informative papers, monographs, memorandums, etc., dealing with their particular approach. These are valuable and should be ferreted out. A representative sampling of published material follows:

Design for Change

Model Treatment Program
Bradley, Smith, Salstrom
National Council on Crime and Delinquency
Crocker/Citizens Savings Bank Building
Sacramento, Calif.

A project, sponsored by the Ford Foundation, which studies the restructuring of the entire treatment milieu—staff, clients, administration, architecture.

The Non-Prison

A New Approach to Treating Youthful Offenders
Bruce Publishing Company
Milwaukee, Wis. 1970
Introduction by Richard McGee,

Book version of Model Treatment Program.

Survey of Halfway Houses in the United States

Oliver J. Keller
Center for Studies in Criminal Justice,
Chicago, Ill., 1968.

Youthful Offenders at Highfields: An Evaluation of the Effects of Short-Term Treatment of Delinquent Boys.

H. Ashley Weeks
Ann Arbor, University of Michigan Press,
Ann Arbor, Mich., 1958.

The Hidden Dimension

Edward T. Hall
Anchor Books, Doubleday & Company, Inc.,
Garden City, N.Y., 1969.

Study of proxemics, the distance regulations in the animal world and in man's culture. A good, basic book on spaces and their messages.

On Social Control and Collective Behavior

Robert Ezra Park
Selected papers, edited and with introduction by Ralph H. Turner,
University of Chicago Press, Chicago, Ill., ca. 1967.

A good sampling of this sociologist's work and views, including concepts of social distance and human ecology, both basic and vital to architectural design.

Others Basic readings in "social ecology" and behavior can be found in the works of Erving Goffman, Humphrey Osmond, Robert Sommer, et al., both in book form and in periodicals.

MULTIPHASIC HEALTH SCREENING CENTERS

GENERAL HISTORY OF MULTIPHASIC SCREENING

Present multiphasic screening programs could be considered an extension of the mass chest x-ray program begun in the 1940s. As the incidence of tuberculosis declined, the usefulness of these particular screening units diminished. However, in the 1950s with the control of most acute diseases, there was a renewed interest in chronic disorders and mass-screening for them.

Today, not only the medical profession but also business and industry are beginning to realize the importance of preventive medicine. Some examples are: the Kaiser Foundation, an industry-founded trust in California, offers computerized screening to its 1.5 million members; the Metropolitan Life Insurance Company plans to provide automated tests for over 50,000 employees; and the Cannery Workers' Union in California, which can screen 20,000 workers during the three-month canning season, makes multiphasic screening available to its members in three 60-ft long trailers.

This use of comprehensive screening both in specialized clinics and in mobile units is the beginning of providing preventive medical care and health education for all people.

FUNCTIONAL ANALYSIS

The following is a resume of tests that could be performed in a multiphasic screening unit. Some procedures are more sophisticated than others and, therefore, might be more difficult to adapt to this situation. The more common tests are enumerated; however, this order does not necessarily reflect proper test sequence. Equipment necessary for the various stations has been included with the appropriate test description.

The screenee presents his appointment card to the volunteer or receptionist. This may be in the same area as registration or it may be in a separate location.

History

A semienclined cubicle or private room is desirable for registration in order to obtain an accurate medical history. The screenee may be reluctant to answer personal questions in an area where others may overhear him. One solution to this problem is to have the screenee fill out a history questionnaire at home before his appointment; however, those who do not read or speak English fluently and those who are illiterate may need help in answering these questions. During return appointments, screenees should fill out an interval medical history.

Relocatable Multiphasic Health Screening, Research and Graduate Center, School of Architecture, Texas A & M University, College Station, Texas Health Services Research, Federal Health Programs Services.

Dressing Area

Dressing areas may be provided for use before or after cardiopulmonary tests, chest x-ray, mammography, thermography, pap-smear, and proctoscopy/sigmoidoscopy. The screenee removes all clothing to the waist and dons a radiolucent disposable gown.

Anthropometry

At this station, the screenee's height, weight, and temperature will be measured and recorded. Various other body measurements may be taken at this time for anthropometrical research projects. A skinfold thickness test (subscapular and triceps) is performed to determine the degree of obesity. (See Fig. 1.)

Vision

The screenee may be examined for visual acuity with a Snellen chart or various types of stereoscopic screening devices may be used to test for fusion, acuity level, color and binocular vision, thus eliminating the need for a Snellen chart. (See Fig. 2.)

After receiving proparacain HCl eye drops or a similar medication as a topical anesthetic, he is tested for glaucoma, increased intraocular pressure, by means of a tonometer. If the electronic tonometer is used, no drops are needed.

He is prepared for retinal photography with phenylephrine HCl or similar drops in one eye 20 minutes before the test to dilate the pupil.

If photography is not used, he may be examined with an ophthalmoscope; however, this requires trained personnel.

Retinal Photo

A fundus camera is used to take a 35 mm photograph of the retina 20 minutes after mydriatic eye drops are instilled to detect any pathology (e.g., disc changes, retinal arteriosclerosis, hypertensive angiopathy, diabetic retinopathy, etc.). Depending on the type and strength of mydriatic drops used, the 20-minute limit may be exceeded. (See Fig. 3.)

Hearing

Hearing perception is tested through measurement of tone thresholds. Various frequencies are tested using increasing and decreasing tone volumes. Audiometric testing may be primarily self-administered by means of a special audiometer. Quality of the earphones is more important than the degree of soundproofing. (See Fig. 4.)

Glucose Ingestion

The screenee is given a 75 gm glucose medium to ingest. This may be dispensed in bottles or in a refrigerated carbonated beverage unit. The time of administration is recorded on the appropriate card. At the end of one hour (determined by the screening unit), a blood sample will be drawn and tested for glucose. Testing exactly on the predetermined hour is vital to this test's accuracy.

Fig. 3 (a) Fundus camera. (b) Portable fundus camera.

Fig. 4 Audiometer.

Dental

Cardiopulmonary

Electrocardiogram An electrocardiogram is taken to detect abnormal cardiac rhythm, conduction disturbances, myocardial damage, coronary insufficiency, and other conditions which alter the normal electrical activity of the heart. The most common method of electrocardiography in this country today employs twelve leads (I, II, III, aVR, aVL, aVF, V1, V2, V3, V4, V5, V6), taken sequentially. An EKG may also be recorded using a single oblique chest electrode. Cady has described a method by which he determined that the "ordered importance of standard electrocardiographic leads were leads V6, V2, and III." An EKG chair has been developed, but it is not yet in production. It consists of an electrocardiograph and an ordinary artificial leather reclining chair with lithium chloride impregnated electrodes. (See Fig. 6.)

Graded Exercise Tolerance EKG A preliminary EKG is recorded. If this is normal and there is no prior history of significant myocardial damage or ischemia, an exercise EKG may be performed to help detect coronary insufficiency. This should not be done without a physician present because of complications that could arise in performing such a test on older patients and members of other high-risk groups.

Phonocardiogram This test is done to record and detect heart murmur and abnormal heart sounds. (See Fig. 7.)

Spirometry The screenee is shown how to use the spirometer (or vitalometer) to determine lung capacity. He exhales into the disposable mouthpiece of a vitalometer tube or into the large double-lumen catheter of a spirometer. The amount of exhaled air and the flow rate indicate the degree of respiratory impairment. A more basic test consists of measuring the screenee's chest circumference before and after inhalation. If inhalation does not increase the dimension properly for age and sex, there is some degree of respiratory impairment. (See Fig. 8.)

X-Ray

Chest A 70-mm posterior-anterior chest x-ray is performed to determine pulmonary, cardiac, or neoplastic conditions. High speed processors currently on the market can be used to develop films in approximately 90 seconds. If 70-mm x-ray is used, a radiologist familiar with such films must be used for their interpretation. (See Fig. 9.)

Flat Plate of Abdomen A flat plate x-ray may be taken to visualize any abdominal pathology. (See Fig. 10.)

Fig. 5 (a) Dental chair. (b) Light, instrument table, cuspidor. (c) Sterilizers. (d) Light and cuspidor.

Fig. 7 Phonocardiograph.

Fig. 8 (a) Spirometer (portable). (b) Spirometer (connectable to computer).

MULTIPHASIC HEALTH SCREENING CENTERS

Dental Both panoramic and apical films of the anterior incisors may be taken at this station. (See Fig. 11.)

Mammography Various x-ray views are taken of each breast to visualize neoplastic conditions in menopausal women. (See Fig. 12.)

Thermography

This test is performed on menopausal women to determine the presence of breast tumors, which are shown by an increase in thermal level at the tumor site. It is more time consuming than a mammogram, since a "cooling down" period of approximately 10 minutes is required (in order to obtain accurate thermal patterns of body heat emitted from the skin's surface). The screenee then sits on a stool 10 ft from the infra-red scanning camera, in which the natural thermal radiation from the breast is recorded and converted to thermal patterns on the cathode ray tube. These patterns may be photographed. Three thermograms (one AP and two oblique) and approximately five isotherms (superimposed pictures which map thermal levels) may be taken. (See Fig. 13.)

Laboratory Tests

Blood Blood chemistry tests can be performed by means of automated multichannel analyzers using a minimum of sample. Techniques such as automatic reagent addition to sample, synchronous flow techniques, reagent-sample mixing by centrifugal force, time-controlled incubations in self-enclosed plastic packages containing chemical reagents, and automatic presentation of sample plus reagents to a colorimeter or spectrophotometer are all available at the current state of the art. Automatic sample blanks and removal of protein or other interfering substances by dialysis can also be accomplished. There are a large number and variety of clinical tests available in different combinations and these comprise almost all of the commonly requested chemical parameters. All multichannel devices currently available possess the capability of interfacing to computers either directly or indirectly (paper or magnetic tape, data cards, etc.) and independently produce bar chart or printed output.

CBC (complete blood count) and STS (serological test for syphilis) should be done on all specimens. Automated equipment is available for both of these tests. The blood sample may also be checked for the presence of the rheumatoid factor (indicative of rheumatoid arthritis) by means of latex fixation test. (See Fig. 14.)

Urinalysis The urine specimen is obtained in the unit. Toilet facilities may be provided near the lab. It should be tested for color, specific gravity, pH, sugar, albumin, acetone, and bacteria.

Parasite Detection Depending on the needs of the screening group and the geographical location, tests to detect parasites may be necessary. Gross examinations of the feces may reveal the presence of worms; however, a microscopic examination may be necessary to detect parasite eggs and small worms. (See Fig. 15.)

Immunization

Space may be provided for administering immunizations against communicable diseases

Fig. 14 (a) Compact multiple channel analyzer. (b) Blood count unit. (c) Centrifuge.

such as diphtheria, measles, polio, smallpox, tetanus, typhoid, and whooping cough (pertussis). Those which are given depend on individual, area needs and age groups. (See Fig. 16.)

Tuberculin Skin Testing

This method of testing for tuberculosis is better than a chest x-ray for preliminary case finding in low risk groups. If the examinee develops a positive reaction after 48 hours, he may then be given an x-ray to confirm or rule out active pulmonary TB.

Pap Smear

Pap smears to detect cervical cancer may be done on all married women, single women over 21, those who have been pregnant, and those under 21 who have proper consent. The exceptions are those in the last trimester of pregnancy. Disposable vaginal specula are available. (See Fig. 17d.)

Proctoscopy, Sigmoidoscopy

Examination of the rectum and the sigmoid (lower portion of the descending colon) by means of a lighted instrument (scope) may be done to detect polyps or cancerous lesions. Disposable sigmoidoscopes are now available which eliminate the need for autoclaving or sterilization (See Fig. 17f.)

Achilleometry

Achilles Reflex This is a test to detect hypothyroidism. The examinee places one knee on a chair or stool with his foot and ankle extending over the edge. His Achilles tendon is struck with a percussion hammer. The reflex action (plantar reflex and extension) is similar to that of the knee jerk. It is exaggerated in upper motor neuron disease and absent in lower motor neuron disease. A photomicrograph may

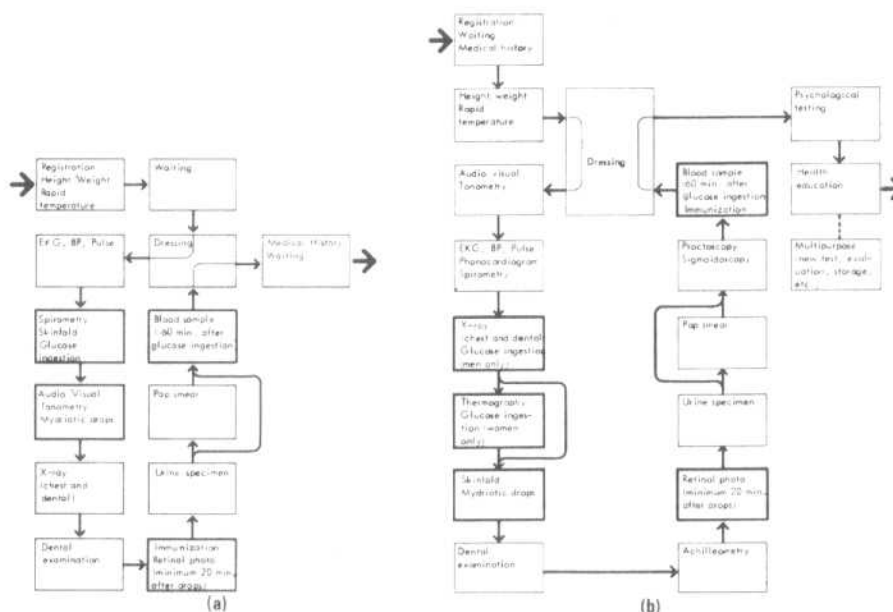

Fig. 21 (a) An enlarged data collection sequence for multiple health evaluation, usable in either a dual automobile or a small transportable unit (12 phase). (b) A comprehensive data collection sequence for multiple health evaluation, usable in a complex transportable unit (17 phase).

be used to record the test results. (See Fig. 18.)

Pressure Tolerance This test is performed on the Achilles tendon to determine the pain threshold of each examinee in order to test for neurological damage. (See Fig. 19.)

Psychological Questionnaire

The examinee either fills out a psychological questionnaire or uses prepunched cards, placing them in yes or no, true or false slots where the results may be tabulated by computer. This test may be performed to evaluate the examinee's mental processes (association, intelligence, imagination, emotion) as well as his responses to various stimuli. Various tests can be used.

Health Education

All examinees should receive specific health counseling at each screening station during or after each test. In addition, provision could be made for a special health education station at the end of all testing procedures for (1) any further questions that may have arisen, (2) guidance regarding the follow-up process, and (3) general health information. This instruction could be done by persons such as physicians, registered nurses, health educators, or trained volunteers.

Visual Aids At this same station, provision should be made for showing health related slides and films and using a rear-screen projector. (See Fig. 20.)

Library A small library area should be provided in which printed health brochures are made available for the examinees to take home. Health related magazines as well as basic books on health and hygiene should be made available for reading in the unit.

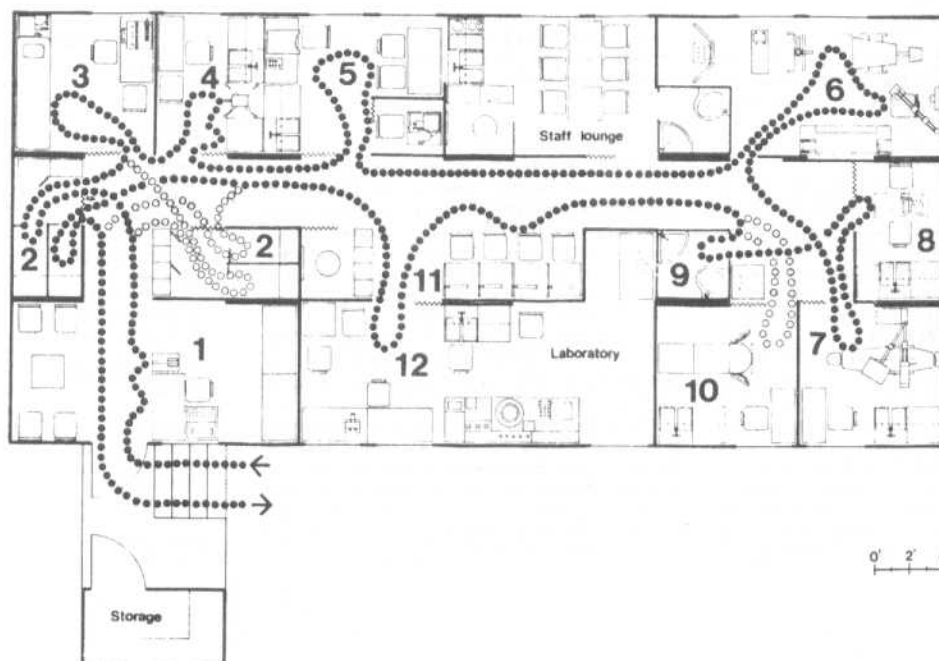

Fig. 22 Work flow of unit with 18 stations. Square and diamond symbols indicate critical interdependence between tests.

MULTIPHASIC HEALTH SCREENING CENTERS

(a)

(b)

Fig. 23 Circulation plan (a) 12 stations, (b) 18 stations.

MULTIPHASIC HEALTH SCREENING CENTERS

First Aid

Space for this station should be provided for the physician or RN to handle any emergencies that might arise during the screening process.

Basic Test Sequences

Basic patient flow charts are represented in Fig. 21a and b. The individual health evaluation tests are grouped according to the ease and convenience of administering each one, and according to equipment size and/or similarity. Functional body systems were given only secondary consideration where grouping of tests was concerned. Each testing group is referred to as a phase, with different numbers of phases comprising a complete data collection sequence. Testing sequence was determined by convenience of arrangement and by required time intervals between phases, e.g., 20 minutes between instilling mydriatic drops and taking the retinal photograph. Phases which are heavily outlined are those whose position in the data collection sequence may not be altered because of critical interdepen-

dence with another phase. All other phases may be rearranged as long as the number of phases between those marked as invariable remains constant. (See Fig. 22.)

Test Durations

Individual test durations have been estimated. After consulting the USPHS, staff members of operational multiphasic screening units, nursing personnel, and medical literature, the following list of assumed times was compiled. Actual times will vary depending on factors such as the type of examinee, staffing pattern, and type of equipment used.

Entrance and exit for the examinees are combined, but the unit provides a separate personnel entrance. The health evaluation process consists of 18 phases. Characteristics of this unit are the separate corridors for men and women and many separate screening stations to use during those tests which require their wearing disposable gowns. After these tests they will undergo the remainder of the test sequence together. The unit also contains a consultation room. (See Fig. 23.)

CHURCHES—BUILDINGS FOR WORSHIP

Church design, which for many years followed long-established rules governing the organization of the space, has been affected by the liturgical renewal all denominations are currently undergoing. In fact, each particular building committee is confronted by some quite disturbing questions and doubts. There are those who ask "Why build?" as well as being concerned with "fixing the form of worship," so that future change is, at best, difficult.

Assuming that these questions are satisfactorily resolved, the building committee and architect can commence developing a program. The church is essentially a gathering place for worship and other congregational activities. There is a functional need not only to provide a comfortable environment but also a special quality that makes worship possible as well as meaningful. It is precisely this search for quality which makes church design so challenging to most architects.

The Site

The "house of worship" is by its very nature an important public building. It speaks to the entire community about the beliefs and aspirations of the congregation. Unfortunately, some congregations worship in churches considerably more "triumphant" than their creed, and it is advisable to strive for simplicity and subtlety.

The church's position on the site will be somewhat determined by this "public image," but some functional considerations also exist. On a limited urban site the church may occupy so much of the land that only building entry and egress are possible. However, if there is room on the site for parking spaces, these will be useful even if the majority of the worshippers walk. The possibility of pulling wedding and funeral cars out of the stream of street traffic as well as dropping off worshippers during inclement weather is worth investigation. The suburban or country church site is usually larger and, with a dispersed congregation, the car parking capability is no longer optional, it is indeed essential. Ample parking areas reached by convenient driveways are functional necessities. There is a stronger entrance relationship to the parking areas and driveways than there may be to the street. Many otherwise successfully designed churches are flawed by the fact that most of the congregation is always coming in the back door. The more generous site permits the consideration of outdoor worship as well as other outdoor activities. The building program must consider these possibilities very thoroughly.

The Plan

The basic determinant of the plan is the programmed relationship between the congregation and the altar area. The emphasis of all faiths is on the involvement of the congregation in the action of the worship service. Plans which suggest an auditorium, with the altar platform viewed through a proscenium arch,

have an unfortunate "performance" aspect. Likewise, plan forms which destroy the oneness of the congregation are less favored.

Since all faiths place emphasis on the spoken word, it is important to consider the ability of the preacher to maintain eye contact with the congregation. "Theater in the round" is not a recommended approach for this reason. Great care must be exercised if the structure requires columns or piers within the worship space for obvious reasons having to do with the sight lines. Although there is no liturgical requirement for seating, the length of most services requires the utilization of a seating device. It is in this particular aspect that the concept of flexible use collides with reality. The church pew has in its favor its relatively modest cost and its orderly appearance. The much more flexible individual chair generally requires more space per person and, even when ganged, requires straightening by custodial help. The desire of the congregation for nonworship uses of the church will determine the type of seating. It is worth noting that some church plans, with the assistance of movable altar platforms and chairs, permit more than one arrangement of the congregation. This is an attractive possibility for church groups interested in innovation.

Plan types are discussed below. All other elements of the church building are related to the worship area. Listed below are the required supporting facilities.

Entry The minimum function of the entry area is as a vestibule from the out-of-doors. However, this space must be sized in relation to the number of occupants, as it will oftentimes act as a lobby. Coat storage may be located here, as well as any required toilet facilities or usher's room and janitor's closet. Pamphlet racks, bulletin boards, and memorial plaques or books are wisely located here rather than in the worship room.

Vesting Room or Sacristy Although each denomination favors a particular nomenclature, the function remains the same. The celebrant requires a room for robing and the storage of vestments and the ceremonial utensils. It is prudent to consider a toilet connected to this room. Often this room will accommodate a guest speaker or another clergyman. Vestments should be stored flat or hung no tighter than three per foot.

It is important that this room be located thoughtfully in relation to both the entry and the worship space. While it is convenient to consider a position close to the altar platform, it will work at a disadvantage if the worship ceremony involves procession through the congregation or if the minister is to greet or bid farewell to the congregation at the entry. Acolytes or altar boys also require a vesting space, which should be near the vesting room for supervision.

Work Sacristy This room may also have many different names, but its function is to provide space for flower arranging, the storage of altar cloths (sometimes also their washing and

pressing), ceremonial utensil storage and cleaning, and candle and candlestick storage. A sink is required, as well as storage cupboards or closets. This room is best located near the altar platform if at all possible.

Optional Support Facilities

Choir Robing Room Depending on the size of the choir, this room may have to be very spacious. Closet space for robes is essential, and it will serve the coats of the choir also. Choir robes should not be stored more densely than four per foot of hanging. Provide a lockable closet for women's handbags.

The choir room can also serve as a rehearsal room if acoustic isolation from the balance of the building is provided. A piano or small electric organ would be necessary.

Church Meeting Room Depending on the congregation, the requirements for a meeting or conference room will vary. A small kitchenette is also desirable.

Expansion Space The sometimes great fluctuations of attendance at worship can be overcome by programming for expansion space. The relationship to the worship area should be planned to ensure good sight lines when in use. If the two spaces are utilized for separate functions at the same time, an acoustic separation is essential.

Plan Types

Rectangular The most commonly utilized plan form is the rectangular, with the altar platform at one end and the seating oriented in rows looking toward the single focal point. A central aisle is usual. This plan is simple, and as long as the altar platform is within the congregational volume, there is no excessive "performance" quality. The primary difficulty arises when the seating capacity exceeds 500, because the viewing distance becomes overly long and worshippers in the rear seats experience a diminished sense of participation.

The illustrated plan (Fig. 1a) shows an entry stair within the seating from an on-grade vestibule. The rear pews are on elevated steps for good sight lines. The choir in this case is part of the altar area. The vesting room is on the vestibule floor level adjacent to the main doors. While the plan is very simple, the movement is almost into the middle of the worship space. This arrangement has some aesthetic impact as well as counteract the tendency for worshippers to concentrate at the usually more convenient rear seats.

Cruciform Plan forms which have symbolic significance are not unusual. The altar area is often in the head of the cross or at the crossing (see Fig. 1b). Depending on the seating arrangement within the arms of the cruciform plan, there may be a loss of a sense of congregational unity.

The church shown in Fig. 1b is constructed with glass walls looking into walled gardens. The altar platform is at the transept. Note that

Religious

CHURCHES, GENERAL

there are numerous entrances, which are related to parking areas.

A fairly large congregation (600) is accommodated without a "gymnasium" effect or very large structural spans. Many times the cruciform plan is chosen less for the inherent symbolism than for the smaller scale imparted to the building exterior.

Central Plans based on the concept of an encircling congregation are to be found in quite ancient churches. Liturgical reevaluation has generated renewed interest in this concept. In addition to the previously discussed problem concerning loss of eye contact by the preacher, certain nonreligious activities taking place in the church may also suffer. Not all the seats will have good viewing angles for motion pictures or slides. Likewise, a lecturer may also find an audience distributed for a span of 270° around the lectern an unusual condition.

Nevertheless, the sense of intimacy and oneness is very great and may overcome all objections. While the accompanying example (Fig. 1c) is hexagonal, many geometric forms are possible. The portion of the space not utilized for seating in this example is used for support facilities. There is the immediate problem that the external form is not internally complete, and this can be a grave fault. The architect should be equally concerned about the deleterious effect on a clearly expressed worship space form when a multitude of small support facility spaces are "tacked on."

"L" or "T" Expandable As stated previously, the varying requirements for worship space seating have caused a variety of plans that are expandable to be developed. The most compelling argument for this type of plan is that the space can be tailored to the number of participants. Unfortunately, this argument has resulted in the building of many churches that are flexible, but in which those who worship in the overflow area feel like outsiders. The ceiling height, floor and wall finish, and lighting of the expansion space should be in harmony with those of the smaller worship area to which it is joined. Worshipers in the expansion space should not get the feeling that they are looking through a doorway. Undoubtedly the best approach is to design the total worship area and then to introduce dividing partitions.

Figure 1d illustrates a church for over 600, of which only 120 are accommodated in the permanent chapel. The expansion space is

sized for basketball, with a small stage platform at one end. The orientation of the seats is deliberately reversed from performance to worship. The enclosed garden visible from the chapel is related more to the expansion space than to the chapel. The altar is rotated depending on the size of the congregation.

Multiform Current interest is focused on a rather random deployment of the congregation around the altar platform. The plan then reflects this arrangement by articulating each group of pews. This nonrigid plan is informal and invites innovation if a movable altar platform and seating are used.

Figure 1e is the plan of a small interfaith chapel with parking on two sides and vesting space for the three chaplains. Fairly conventional wood framing is supported on columns so located as to avoid interference with viewing angles.

Multifocus A relatively new liturgical innovation has been included in the illustrations since it may develop into a significant plan form. Here the thought is to move the focus of interest with the liturgical actions around the space. Fixed seating is not compatible with this approach, nor is it likely to be used for large congregations because of the possibility of confusion.

The Dutch church plan (Fig. 1f) shows the seating used for preaching and singing, with a large standing space about the communion table for that part of the service.

Parallel Seating While not entirely unique in the history of church design, parallel seating is not a common arrangement. As illustrated in the synagogue plan (Fig. 1g), this approach is worthy of thoughtful examination. The problem of expansion is also neatly solved.

Organ and Choir Location

For many years, the choir has been located in the church either in monastic fashion before the altar or in the "voice of angels" position in the choir loft. Due in no small part to the relocation of the altar so that the celebrant can face the congregation, the choir location is being rethought.

Possibly just as worship service is losing its performance quality, so too the choir is being asked to lead the congregation's singing rather than to perform before it. Hence locations of

the choir within the congregation are being considered.

Illustrated are five alternatives:

1. Behind altar (Fig. 2a), the choir is less visible but still easily heard. Unfortunately the members of the choir are not part of the congregation and have poor opportunity to worship properly or to feel that the sermon is also directed to them.
2. Before the altar (Fig. 2b). Here, the choir is segregated but part of the congregation.
3. Rear of the church (Fig. 2c). The choir is part of the congregation, but this situation is not much different from that in the choir loft.
4. Choir alcove (Fig. 2d). This arrangement has many variants, and it can be very effective.
5. Within the pews (Fig. 2e). A simpler version of the "before the altar" arrangement. The significance of the choir is very much reduced.

It should be emphasized that in all cases the organ will be best located where the organist can see the action at the altar as well as cue the singers by virtue of being seen when giving signals. The organist is a potential distraction to the rest of the congregation, and it is therefore prudent to construct low walls about the instrument.

Pipe organs are too expensive and take too much room to be treated as an afterthought. A church which expects to install a pipe organ must plan for that instrument, since introducing an instrument later without proper provisions is almost always unsuccessful. While other musical instruments have been successfully used in churches, the advent of sophisticated electronic organs permits even very small congregations to consider their use without sacrificing quality.

Other Planning Considerations

Acoustics Small churches seldom have acoustic problems if the space is "live" (i.e., somewhat reverberant). More errors are committed by excessive use of sound absorbing materials than by restraint in their use.

Echoes and "dead spots" will have to be anticipated in churches sized for more than 600, but even then reasonable precautions will suffice.

Public address systems are recommended

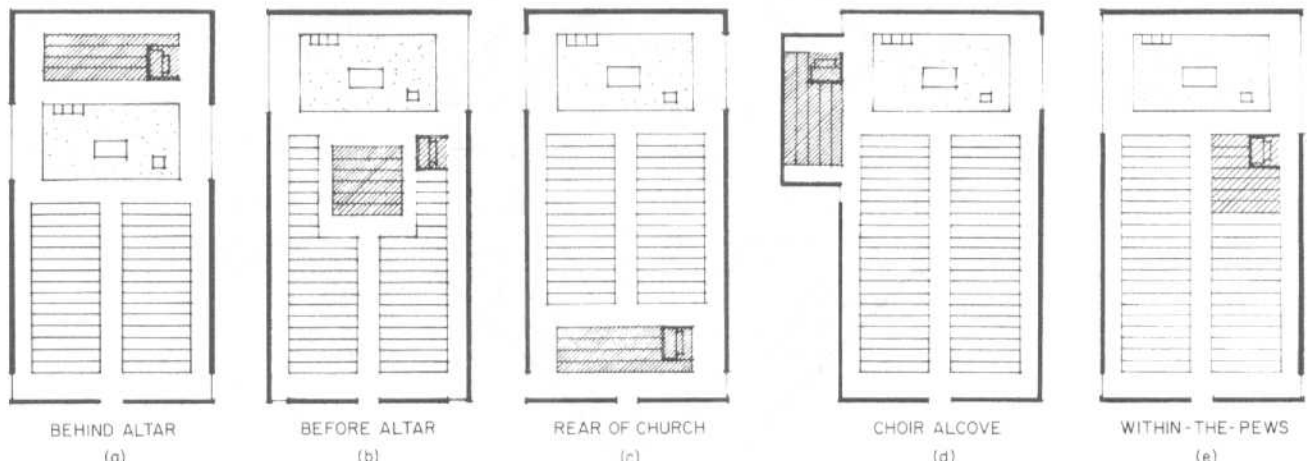

Fig. 2 Possible locations for the choir.

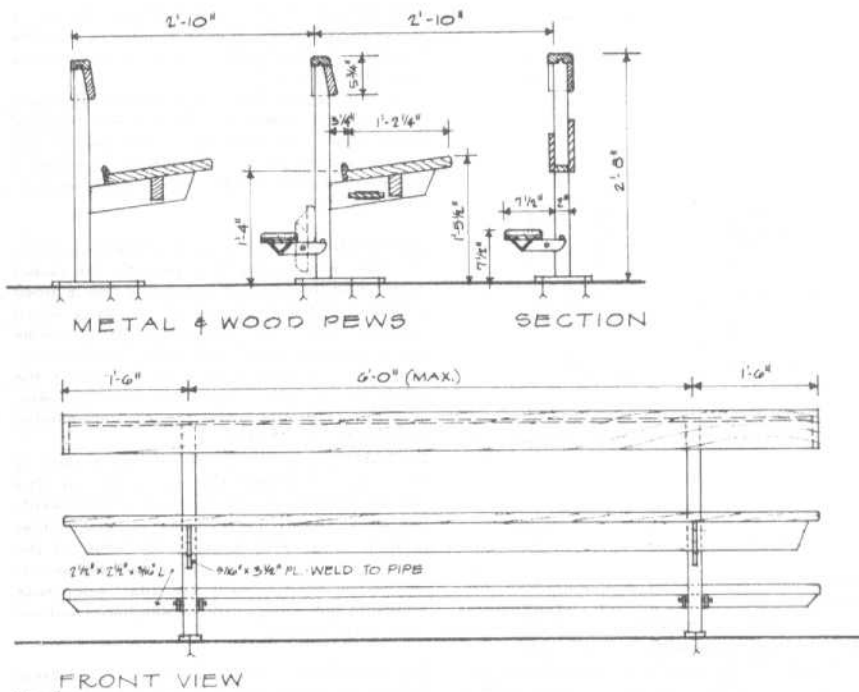

Fig. 3

for all but the smallest churches. A trained speaker can usually be very well heard, but amplification is a help to the many untrained and unaccustomed speakers using the lectern. If an ambitious music program (chamber groups or recitals) is programmed, then a competent consultant is recommended.

Air Conditioning In an age when every public space is usually air-conditioned, it is imprudent to overlook this aspect of providing a comfortable environment for worship. The use of the church during the summer months, the hour and length of the worship service, and the

anticipated size of the congregation will determine the best type of system. However, it is imperative that the architect and his consultant give due consideration to equipment and air noise. A church with a high background noise generated by poor equipment and register selection has failed to provide a proper environment for worship.

Lighting Natural The introduction of natural light into a worship area can animate the space and create that sense of the unique which should be part of the architect's goal. The programmatic and liturgical emphasis will

Fig. 5

Fig. 4

dictate how natural light will be admitted and what it is to do.

One word of caution: avoid the common pitfall of forcing the congregation to look into the sun. If the celebrant is silhouetted against backlit glass (even diffused or stained), it will create considerable discomfort. Although most worship services are in the morning hours, there will be weddings, etc., which can make low-lying westerly sun a great problem.

Artificial High light levels are not required in worship spaces. Thirty to fifty footcandles are quite adequate for most visual tasks in a church. Hanging fixtures in churches are not mandatory and are potentially distracting if there are too many or if they are too ornate. It is prudent to consider how the fixtures will be relamped, since the life of an incandescent lamp is relatively short and the pews make ladder erection difficult. Locate lighting controls so that proper control is possible for non-worship uses. Outdoor lighting is also important, since the church will be utilized at night and the access paths to the building must be defined.

Churches have been the targets for some of the increasing vandalism all buildings have experienced. Therefore outdoor security lighting, controlled by a timer, is recommended.

Sizes

Gross Area For purposes of establishing pre-

Fig. 6

Religious

CHURCHES, GENERAL

Fig. 7

liminary space requirements, allow 10 to 12 sq ft per seat. This would include moderate space for altar platform, work sacristy, vesting room, and vestibule. If only the seating area is considered (including aisles), allow 8 sq ft per person.

Seating If pews are utilized, some building codes will gauge capacity on the basis of 18 in. of pew length per person. Actually, this density will only rarely be achieved, and the usual space per person will be 22 to 24 in. Back-to-back dimension will average 36 in., with a minimum of 33 in. (especially if a kneeler is contemplated) and a maximum of 42 in. The widest

spacing will actually be uncomfortable for kneeler use. It is wise to provide storage space for prayer books or hymnals on a shelf below the seat ahead or mounted on the seat back. The foregoing dimensions will hold true for folding or stacking chairs. Allow space in the aisle for funeral catafalques and candles. (See Fig. 3.)

Altar Size varies from 5 ft-6 in. to 8 ft long by 28 to 48 in. wide by 40 in. high. The altar need not be rectangular, but in any event its historical beginning was as a table and it is reasonable to retain some of that image. (See Figs. 4 and 5.)

Altar Platform Four to six inches in height is generally sufficient. It is imperative to plan the platform for the furniture and the movements of all those on it.

Weddings are often performed on the platform and space between the altar and the platform edge will have to accommodate the clergyman and the nuptial couple (sometimes kneeling at a prie dieu or kneeling device). (See Fig. 6.)

Confessional In those churches requiring them, the custom is to provide a space for the seated priest with the penitent kneeling within a small cubicle and speaking through a heavily veiled opening at the priest's ear. It is also possible to use a more natural conference room setting, but the arrangement must be such that the confessor (priest) cannot see the penitent, in order to preserve the required anonymity.

Candlesticks Candles varying in size from 1 to 2½ in. and in length from 9½ to 33½ in. The holder can be on the altar or on the floor beside the altar. Overly tall candlestick and holder combinations may obstruct the view of the clergyman. It should be mentioned that an airstream directed toward the altar will cause annoying flickering of the candle flame and uneven wax burning.

Lectern or Pulpit Provide a sloped (adjustable height) surface with lip to retain a book placed on the surface. The pulpit width varies from 24 to 36 in. Depth measured horizontally is a minimum of 16 in. (See Fig. 7.)

Communion Rail If a rail is required, the height should not exceed 36 in. The communion rail is considered to be a symbolic extension of the altar table, and as such it is desirable that it have a broad top (6 to 8 in.).

By MAURICE R. SALO, AIA, Consulting Architect to the Lutheran Church in America

THE SELECTION OF THE SITE

The selection of the site is the most important decision to be made by the building committee, since it sets limitations for the potential area and volume of the proposed church structure and profoundly shapes its character and determines its future growth, development, and importance to the community and parish. The following factors are major considerations:

1. The character and stability of the environs of the site
2. Accessibility to the site for the membership
 - a. Relationship to highways and secondary roads
 - b. Coordination into the regional plan and traffic pattern of area affected
 - c. Provision of ample parking area
 - d. General contours of the property
 - e. Soil characteristics
 - f. Presence of rock and ledge outcroppings
 - g. Presence of water problems
 - h. Availability of utilities

The practical elements and component spaces required by the church are as follows:

1. The church room (liturgical center) areas for intimately related activities
 - a. Narthex (entrance vestibule)
 - b. Chancel (including altar, pulpit, and lectern)
 - c. Choir and organ facilities
 - d. Baptismal font and facilities
 - e. Sacristy
 - f. Minister's study
 - g. Church tower
2. Administration
 - a. Secretary's office
 - b. General office
 - c. Mailing, printing, and reproduction rooms
 - d. Minister's office
 - e. Assistant minister's office
3. Church school
 - a. Kindergarden
 - b. Intermediate classes
 - c. Junior classes
 - d. Senior classes
 - e. College group facilities
 - f. Adult facilities
 - g. Family counseling facilities
 - h. Visual education facilities
 - i. Boy Scout rooms
 - j. Brownie rooms
 - k. Library facilities
4. Social hall
 - a. Auditorium with stage or dais
 - b. Kitchen facilities
 - c. Coat rooms
 - d. Toilet facilities
 - e. Storage rooms (generous for materials, seats, and equipment)
 - f. Lobby or foyer
5. Church parlor with fireplace
6. Kitchenette
7. Parking
8. Landscape—gardens and similar features

Note: The above facilities are desirable for complete church activities. However, each parish has its own special requirements, which

are specified in the building committee's brief. There some elements can be omitted and some areas may be assigned to multiple use. All these elements are critical in determining the design and establishing the cost of the building program.

After the selection of the site, the following practical elements and spaces required for a church structure must be considered by the committee and incorporated into their program or brief. (See Fig. 1.) Administration is centrally located for control. Other elements are related but adapted to dictates of site, to the architect's interpretation of the problem, and to suggestions of building committee.

THE NARTHEX

The narthex is the vestibule or entry into the church room. Its shape is, of course, suggested by the basic plan of the church complex. It is recommended that it be at least 10 ft wide to permit facile movement of the congregation and the usual personal greetings to the parishioners by the minister. It is well to locate toilet facilities, coat rooms, and similar conveniences discreetly off the narthex or in other accessible areas, since there is no rigid rule except convenience to determine their disposition.

THE CHURCH ROOM

The church room on the main body of the church today may assume many forms due to the demands of site and the architect's interpretation of the building committee's brief.

Essentially the space must have dignity and strength to carry out the spirit of worship and logically contain the twelve elements outlined subsequently in this article.

A center or direct aisle from the seating area is essential to permit weddings and similar activities to function properly. The center aisle should not be less than 5 ft wide. Side aisles should not be less than 3 ft wide.

Sculpture, painting, and stained glass may be used, but with good taste and properly placed to enhance the room and to express its special character. Art has always been a basic vehicle of man to express the beauty and logic of the universe and for a moment's escape from the sometime prosaic reality, and therefore, it is a fitting agent to bring about the awareness of divine truth.

The church room (liturgical center) and appurtenant areas for intimately related activities are as follows.

UNICAMERAL SPACE (CHANCEL)

The chancel is the climactic point of the churchroom and the main center of liturgical activities. Therefore special attention should be given to all its elements and appointments. The chancel or unicameral area in today's church is an integral part of the church room. A distinct separation of these elements should

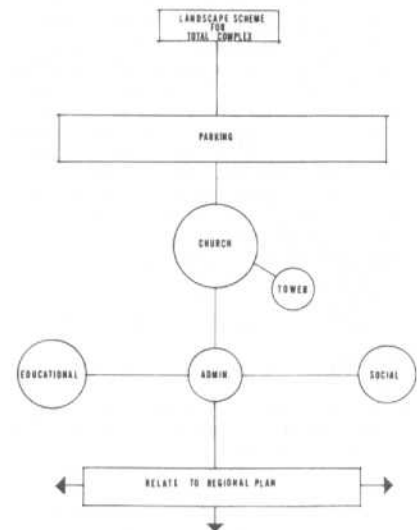

Fig. 1 Diagrammatic relation of elements of the Lutheran church.

be avoided and the clear separation of celebrants and worshipers should not be stressed. It follows that the chancel space should extend as far as practical limits permit into the church room, so that all can equally participate in corporate worship.

It is the present feeling that all liturgical centers are equally holy. The historic liturgical center with its concentration of worship at the altar and reredoes as an essential element in the church room, is changing, although some Lutherans still preserve an attachment to this traditional treatment.

There are great possibilities in the placement of the chancel and its elements. It may be located centrally or asymmetrically as long as its activities are within a comfortable vision range.

The chancel should be raised three steps, each of which is not more than 6 in. high, with treads a minimum of 16 in. wide. A clear aisle with a minimum width of 5 ft should be provided for convenient circulation around the perimeter of the chancel. We are not illustrating characteristic arrangements since the range of possibilities is too great. However, in the discussion of the choir arrangements, some suggestions will be made.

ALTAR

The altar is the most sacred element in the chancel, traditionally as well as in terms of today's worship. It usually reflects the concept of the Last Supper and should bear the character of a table. Its design treatment should reflect dignity and should have meticulously thought out details. The special treatment of this element must be the responsibility of the architect. He must properly relate its material and character to the total church room design. Figure 2 is a sketch of an altar, with dimensions to be used solely as a guide.

CHURCHES, LUTHERAN

THE PULPIT

The pulpit is the most actively used element in the chancel. It is dynamic, as opposed to the more static holy appointments. It is a setting from which the preacher brings the Gospel and the word of God to the worshipers. It should be prominently placed in the chancel without obscuring the view of the altar and other elements of the chancel. The centrally placed pulpit in a circular room, in the author's opinion, is not sound, since it does not permit the preacher to be seen by all. It should be comfortably located, seen by all, so that the preacher's visage, movement, and use of hands can be viewed, enabling him to deliver his message forcefully and to have complete communication with every worshiper. We suggest that the pulpit be raised two or three steps to raise the preacher's stature—to give him greater dignity—for at these moments he is the apostle of God and more than an ordinary man.

The pulpit must be provided with the following elements:

1. Bible rest
2. Shelf under Bible rest for notes and papers
3. A light over the Bible rest for reading purposes
4. Microphone—with all its conduits and devices shrouded in the construction of the pulpit

The design character should be left to the architect, as a standard form is not possible due to the variability of the church room design. Materials are optional, but they are related to the church design and should have inherent dignity and strength. Figure 3 is a sketch of a pulpit with critical dimensions to be used solely as a guide.

THE LECTERN

The lectern is a smaller reading desk and is an element in liturgical activities. It is used in conjunction with the pulpit during services.

It may be omitted at the discretion of the building committee. This is particularly true in the design for smaller churches. The following elements are essential to the lectern:

1. Bible rest
2. Reading light over the Bible rest
3. Microphone (electrical elements to be concealed)

Figure 4 shows the lectern's critical dimensions, but this sketch is not to be taken as a criterion for its design.

THE COMMUNION RAIL

In many Lutheran churches the communion rail is omitted and the communion elements are served directly from the altar table while the communicants are standing.

In such instances where a communion rail is desired, it should not be more than 2½ ft high and located around the elements of the chancel to permit maximum participation at one time with easy movement flow to the rail and to the pews. The step before the rail should not be less than 2 ft wide. As in the case of the other elements of the chancel, the design should reflect and be in character with the design idiom of the church room. Figure 5 shows critical dimensions, which may be used as a guide.

CHOIR AND ORGAN FACILITIES

The particular location of a choir is usually determined by the minister, choirmaster, and

organist for its suitability to the required services. The decision on its placement must be made by the committee early in its deliberations and the architect must be advised as soon as possible, since the choir is a major element affecting the shape of the church room.

There are five possible arrangements for the choir and many interpretations for each type. These five basic choir locations are as follows:

1. Split choir in the chancel
2. Choir centrally located behind the altar
3. Asymmetrically located choir placed on one or the other side of the chancel
4. Choir placed in the seating area of the church room
5. Choir in the rear balcony

An analysis of the five basic locations of the choir and their relative merits follows.

The Split Choir in the Chancel

This type of choir setting (see Fig. 6a) is traditional, but most churches today have found it the least suitable for present-day needs. It has the following advantages:

1. The members of the choir are a visible part of the congregation and participate in the total worship.
2. The altar, placed between the ranks of the choir pews, has a dominant focal position.
3. The service is enriched by the color of the choristers' vestments, by their trained behavior, and by their organized singing.
4. Musically, this arrangement creates some problems, since the singers cannot be centrally directed. The organist needs the aid of mirror devices to see the singers perform in unison.
5. It creates further a sense of separation between the singers, the professional clerical celebrants, and the laic worshippers, reflecting

the complete separation of these functions which was characteristic of the medieval church.

6. This scheme frequently forces the location of organ pipes to be opposed on the side wall, since it implies a central reredos. Musically, the organ should speak directly to the worship room. Although this side arrangement can be reasonably handled, it would be a compromise. As stated earlier, this scheme is not sympathetic to today's church concept. There are other approaches to the problem which should be studied for their suitability to the congregation before type of choir plan is decided upon.

Choir Centrally Located

The choir may be located centrally, behind the altar. Theoretically this is sound. This arrangement permits a central position for the organ console. It enables the choirmaster to face the choir directly and to conduct the music properly. (See Fig. 6b.)

However, it places the choir personnel behind the altar and the pulpit, which can distract from the serenity of the service. A number of devices can be used to offset this difficulty. For instance, the choir stalls may be lowered, so that singers are not too visible when performing. Another possibility would be to use perforated screens to make the choir's movements less conspicuous.

The organ screen, of course, is best located behind the altar, so that it voices directly to the church room. This arrangement has many advantages, but it makes the organ conflict and compete with the altar and pulpit. With a disciplined choir, however, this plan has interesting possibilities.

Fig. 2 (a) Schematic altar elevation. (b) Schematic altar plan.

Fig. 3 (a) Schematic plan of pulpit. Minimum dimensions. (b) Schematic section of pulpit.

Fig. 4 Schematic lectern elevation. (a) Front. (b) Side.

Fig. 5 Schematic section through communion rail.

Choir Located Asymmetrically

This arrangement (see Fig 6c) places the choir facilities at the front of the church next to the chancel area. It causes the design of the church itself to be asymmetrical in plan and volume, and it poses a difficult problem for the architect who seeks to develop a design of proper repose with ecclesiastical dignity. This plan has the advantage of avoiding direct competition between the choir and the chancel and placing all liturgical activities within comfortable vision range of the congregation. It permits good musical direction and provides a control position for the console and organist.

Choir Placed in the Seating Area of the Church Room

This (see Fig. 6d) is a novel departure from tradition. It has the advantage that the choir and parishioners worship in concert. Perhaps it also deemphasizes the choir and its colorful role in the worship ritual. The decision for this arrangement must be based on the minister's attitude toward the service and on the feelings of the building committee. The console of the organ can be membered into the pens of choir area and so arranged that the organist faces the choir and has complete control of the singing. The organ space and its elements must be closely related to the choir's location.

Choir in the Rear Balcony

This (see Fig. 6e) arrangement is ideal from the

musician's point of view since the direction of the music is good and the organist can be so placed as to be in perfect control of the singing. The organ can be effectively located behind the choir. From the point of view of the worship, the choir is remote from the main church room and not visible.

This arrangement will provide an effective musical background for church services, and many successful examples of this scheme exist. It does, however, conflict with the present-day concept of corporate worship. The committee must decide to what extent its ideas on worship conflict with this musically excellent arrangement.

THE ORGAN

The organ is a major element in the design of a church space, and adequate volume for its housing, air supply, and electrical elements must be provided.

Often today, pipes are exposed in the interior walls of the church room and become an interesting part of the church decor. We noted earlier that an organ builder must be consulted in the earliest stage of church planning as the organ cannot be installed as an afterthought. The form of the church must be designed to ensure maximum purity of tone and to provide the proper acoustics. The excessive use of sound-absorbing acoustical material will strip the overtones of the various pipes—particularly double reed stops, bases, and tones in the treble clef.

THE BAPTISMAL FONT

This unit is an important part of liturgical activities and must be placed in a prominent area of the church room—that is, in the chancel or in a space conveniently close to it. It must be in the visual range of the congregation so that all can participate in the baptismal rites.

The baptismal font may be a fixed element or it can be a movable unit which can be placed conveniently when required. If it is a fixed unit, a proper setting must be provided.

Figure 7 gives some basic dimensions to be used as a guide for its design. The concept can be simple or elaborate, but it must be related in character to the overall design of the church room.

THE SACRISTY

The sacristy is a room located adjacent to the chancel. It is a practical space for flow arrangement, for the preparation of communion elements, and for the storage of items required for the activities in the chancel. It generally contains a double sink with hot and cold water, a refrigerator, and base and wall-hung cabinets. Its design may be simple and materials may be chosen as economically as desired as long as they are in good taste.

No illustrative drawing is required for this space since it varies in so many instances, but it must function smoothly. At least two people must be able to work here at the same time. It must have direct access to the chancel and a secondary exit to a hall or corridor outside the church area.

MINISTER'S STUDY

A minister's study or room is adjacent to the chancel, with direct access to the chancel and egress to a hall or corridor. This room should provide space for a desk and a number of chairs, files, coat closet, toilet, and a shower bath. It is convenient for last-minute reviews of his sermon, guest speakers, conferences, and similar purposes.

This room should be a dignified space and should have a reverend atmosphere. Since this area varies a great deal in its form—because it is related to the particular church form of which it is a related element—no sketches will be provided.

CHURCH TOWER

The church tower, though not an integral part of the church room itself, will be discussed herein since it is a symbol of the church and expresses the religious character of the total church complex.

Today it is often felt that the church tower involves an unnecessary expense and that a properly designed church is sufficient to express the spirit of Christian worship. However, a church tower or campanile has long been associated with ecclesiastical structures and to many it has a symbolic value beyond its cost or its logic. Perhaps it does conflict with the criteria of present-day attitudes. But it is an understandable symbol of worship and an abstract witness to the Christian spirit; therefore it may justifiably be used.

It does provide an opportunity for abstract sculptural expression and keynotes the total spirit of the church building complex. This is a matter for the building committee to decide. We believe that it is a valuable device to proclaim positively that this is a church. No sketches are provided, for there are infinite possibilities in its design. It has another positive value in that it can house a carillon.

ADMINISTRATION

Administration consists of elements outlined earlier in this article. These rooms are sized to meet the specific requirements of the committee's brief.

Special attention should be given to the minister's offices, to give them ecclesiastical char-

acter. The minister's office should not be less than 12 by 20 ft clear and should contain closets, bookshelves, and toilet facilities.

CHURCH SCHOOL

Classrooms should not be less than 24 by 32 ft. Small rooms are too restrictive and are not adaptable to program changes. It is best that adequate natural light be provided, and light areas should not be sacrificed for design effects.

The kindergarten should provide 30 sq ft per pupil because of the nature of kindergarten activities.

The architectural treatment should reflect the rhythm and character of the church building.

SOCIAL HALL

This should provide seating equal to that of the nave. It should be a pleasant area and well correlated to the exterior landscape features if possible. The ceiling should not be less than 14 ft clear if possible.

CHURCH PARLOR

This is a very desirable space and serves many functions. It should not be less than 24 by 14 ft in plan dimensions and should have a ceiling at least 12 ft high. The room should have a clublike character with suggestions of its basic religious relationship. It should be comfortable and pleasantly furnished and decorated.

PARKING

Parking should provide one parking space for every five persons in the church room seating. Its arrangement necessarily is a function of the total landscape pattern.

LANDSCAPING

The landscape is an integral part of the total architectural concept and should properly relate to building plans and mass. It is recommended that a professional landscape architect be consulted to achieve the best results.

CHURCHES, UNITED METHODIST

ORGANIZATION

The main entrance to the building should be easily accessible from the parking area, and should be designed with a drive up and canopy entrance. This permits covered access to the building during inclement weather.

The building should be organized so that people can easily orient themselves once inside the front doors. A key feature in this kind of arrangement is a large, centrally located narthex that serves as the circulation hub of the building. A person should be able to proceed directly from the narthex to the sanctuary, fellowship hall or classrooms. For convenience, the church offices and restrooms could also be located off this area. Not only does this make them more accessible, but it also enables the secretary to monitor the main entrance from the church office. Fig. 2 illustrates this kind of arrangement.

SANCTUARY

Basic Premises on Which the Recommendations Are Based

- I. The purpose of erecting a building is to provide a place where people may assemble for worship, fellowship, education and prepare for service.
- II. People and what they do are the major concern of the church. The building forms a background for the action and is secondary to the gathered congregation and the liturgy.
- III. The essential elements for worship consist of a place for the preaching of the word and the right enactment of the sacraments.
- IV. The aim of worship is "to focus attention and to suggest and direct appropriate human responses to the divine-human encounter."^{*}
- V. Theology does not directly influence architecture. Theology (or beliefs) does influence liturgy (what we do). Architecture is a result of efforts to provide a setting for the liturgy.
- VI. Our church buildings should celebrate the conviction that God is present in our lives in this age.

WORSHIP ROOM

The worship room is to be designed to assist the liturgy. The liturgy consists basically of provisions for the preaching of the word and the sacraments of baptism and holy communion. Since the ministry of the word and the sacraments are of equal importance, the architectural plan should give emphasis and stress to the pulpit, table and font.

The worship room may also be used for other functions such as: confirmation and reception of members, weddings, funerals, choir programs, drama, education, and fellowship. Because of this, the pulpit, table, and font should be portable.

^{*} Professor Albert C. Outler, "A Methodist Comment About Methodism," *Worship and Christian Unity*, April 19, 1966, p. 2.

Materials taken in part from publications of the Office of Architecture, National Division, Board of Global Ministries, the United Methodist Church. For further information write Douglas Hoffman, Office of Architecture, United Methodist Church, 475 Riverside Drive, Room 307, New York, New York 10027.

The design and arrangement of the worship room should reflect the fact that the minister and congregation come together in a corporate act of worship. The platform on which the pulpit, table, and font are located is a distinct area because of the functions involved, but it should not be separated from the congregational seating space.

Since the major emphasis is upon preaching, baptism, and communion, architectural features such as windows, reredos, or dorsal should not distract from the liturgy. The seats for the minister

should also be located so that they do not compete visually with the more liturgical centers unless used as such.

Sermon

The pulpit is a place designed specifically for the preaching and reading of the word of God. This does not exclude the possibility that in some instances this function may take place elsewhere in the room.

The location of the pulpit affects the relation-

Fig. 1 Site location.

Fig. 2.

CHURCHES, UNITED METHODIST

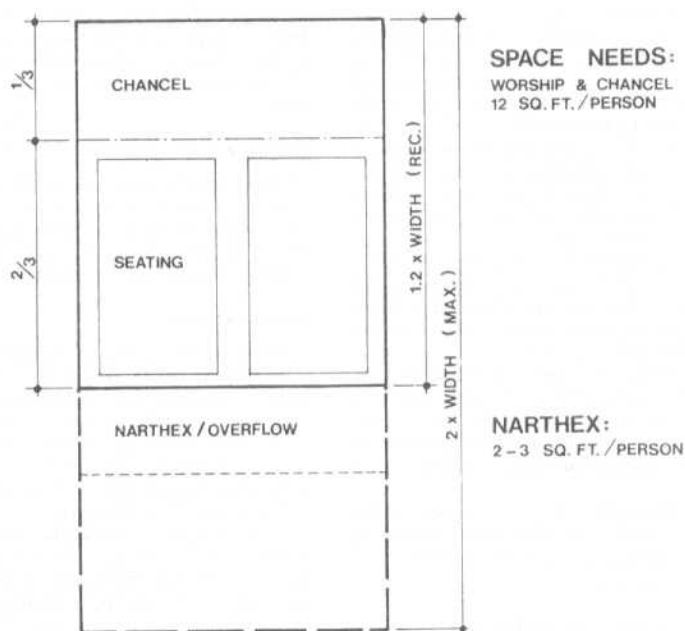

Fig. 3 Worship.

ship between the sermon and the congregation. The minister must be able to see the congregation and the congregation must be able to hear and see the minister.

Listening to a sermon is a corporate activity. The minister must be aware of the response of the congregation to the sermon even though the response is unspoken. Conversely, the congregation needs to see the minister. They need to see his facial expressions and his gestures. This can be achieved by elevating the pulpit, so that even those seated in back of the room can see the minister.

The rapport between the minister and congregation can be destroyed, however, if the pulpit is raised too high or if it is located at too great a distance from the congregation. If raised too high, the viewing angle becomes oppressive for those seated nearby. If placed too far from the congregation, the contact between the minister and the people is lessened.

Choir

The function of the choir is to lead congregational singing (hymns), to sing to the congregation (anthems), and to sing on behalf of the congregation (choral responses). In addition, many choirs offer sacred concerts on special occasions. The choir should be located so as to best fulfill these functions.

The choir should not be placed behind the pulpit or table facing the congregation or in divided choir stalls in a deep chancel where they may be a visual distraction during the service. Their task is to lead worship, not to be performers of musical acts.

The organ console should be located so that the organist can direct the choir. The organ chambers should be located so that the organist may balance the music of the organ and choir. The director should be easily seen by the choir without being conspicuous to the congregation.

Space should be allowed in the design of the worship room for the use of instruments or unusually large choir groups on special occasions. If

chairs instead of pews are used in the choir loft, this space may then be used for the placement of musical instruments.

Congregational Space

The worshiping assembly should be situated so as to suggest their active role as participants in worship. Worship is a corporate activity. It involves the minister, the choir, and the congregation. It does not represent a performer-spectator

relationship. The size, shape, and arrangement of the room should emphasize the understanding that worship involves the entire congregation in the service. This can be achieved by bringing the congregation closer to the liturgical centers and by planning for a level floor. Conversely, long narrow rooms which place a large number of the congregation at a great distance from the minister and rooms which have sloping floors and balconies which emphasize the spectator-performer relationship should be avoided.

In order to provide as much flexibility as possible in adjusting the seating for different occasions, services, numbers of worshippers and future trends, chairs are recommended instead of pews. The chairs should be comfortable, attractive, durable, and reasonable in cost. They should be firmly linked together when in use and designed to be stacked when not in use.

Chairs are recommended for the following reasons:

1. For some services, such as those which emphasize preaching, there may be advantages in eliminating the center aisle so that the congregation sits together as one group, further emphasizing the corporate aspects of worship.
2. For those occasions when the attendance is lower, the number of seats may be reduced, the aisles may be made wider, and the spacing of the seats and rows increased.
3. For some communion services the church may desire to place the communion table in the congregational seating space with the people grouped around the table.
4. The church may desire to use the sanctuary for youth or adult church school classes. Chairs would allow several groups to meet and arrange their seats in a circle or small group.
5. Different functions require aisles of varying widths. For a choir or offertory processional, a 5-ft aisle is usually sufficient. A wedding processional could use a 6-ft aisle, and a funeral processional needs a 7-ft aisle. (See Fig. 4.)

Fig. 4 Aisle widths in the sanctuary: the minimum recommended sanctuary aisle widths needed for the various liturgies.

CHURCHES, UNITED METHODIST

Order of Worship

The normal service for most churches places emphasis on the spoken word—invocation, prayers, reading of the scriptures, responsive reading, affirmations, sermon, and benediction. The worship room should be designed to provide the best possible acoustical environment for these functions. It is imperative that the minister be able to communicate directly with the congregation without having to resort to artificial aids such as a public address system. The size and shape of the room and the materials employed should contribute to the effectiveness of the spoken word.

The Order for the Administration of the Sacrament of Baptism

The baptismal font should be located so that it is convenient for all to see. The ceremony should be visible to the entire congregation. The candidates should be able to approach the font if baptism by pouring is desired, and there should be sufficient space for the minister, parents and sponsors. The basin should be sufficiently large to make pouring possible (no less than 15 inches in diameter), and the use of water should be visible and audible. The font should be of sufficient size and prominence to remind people of their baptism and to suggest the importance of this sacrament.

The Order for Confirmation and Reception into the Church

The service should take place in view of the entire congregation. It might be helpful if the candidates step up into the raised chancel area so that they may be easily seen when they stand or kneel. There should be sufficient space for a considerable number of candidates to kneel, only one row deep, and space for the minister to conveniently lay his hands upon their heads while they kneel.

The Order for the Administration of the Sacrament of the Lord's Supper or Holy Communion

Traditionally, Methodists have served the elements to those who kneel at the communion rail. Because of the time this method may consume if individual table dismissals are considered necessary, many large churches serve the elements to those seated in the nave.

Both methods will probably be continued, and in addition it may also be possible to consider serving communion to those who stand around the table. Apparently this was one of the methods used by the early church.

If communion is to be served to those who stand around the table, a rail is no longer needed. In this case the table should be easily accessible to the congregation, and there must be sufficient space around the table for the minister and his assistants as well as a large number of communicants. The entire congregation should be accommodated in at least ten tables and five would be a better goal, either standing or at a rail.

The communion rail was originally designed to protect the table from profane and irreverent treatment. It now serves as a rail for support while people are kneeling and to hold the empty cups. It should no longer be designed as a barrier to prevent one from entering a "holy of holies."

The architectural solution should not determine whether the elements will be offered in the chancel or in the nave seats. The church should decide how the service is to be conducted and the architectural plan should be a result of efforts to provide a meaningful setting for the liturgy.

Ideally, the room should be designed to accommodate both methods of serving communion. This will allow communion to be served in the pews now, if this be the wish of the church, and yet it will permit others to conduct the service in the chancel if this be their desire.

The Commission on Worship of The Methodist Church does not recommend self-service communion. With this method, the elements are placed at the rail before the start of the service and each person serves himself.

The communion table provides a surface for the placement of the communion elements. It is essentially a table. The size of the table should be scaled to the person or persons involved and the liturgical action about it.

The table should be free-standing so that the minister may stand behind the table and face the congregation for parts of the service. The table may also be used to receive the offering and provide a place for a small, portable book rest.

It is often desirable to provide a small table or credence shelf to hold flowers, empty offering plates, the communion cloth, lids, or other items while not being used.

The Order for the Service of Marriage

The aisle leading to the chancel should be of ample width (6 to 7 feet) for the procession of the wedding party. There should be a way to signal the organist when the bride is ready to make her entrance.

There should be sufficient space at the front cross aisle for the wedding party. If the ceremony takes place on the raised chancel area, the wedding party will not block the congregation's view of the couple. There should be provision for the couple to kneel after the ring ceremony.

The Order for the Burial of the Dead

There should be sufficient space for carrying the casket from the front door of the church with a minimum number of stairs and slopes. The doors should be sufficiently wide. The aisle leading to the chancel should be at least 6 feet, 6 inches wide and 7 feet is better if pallbearers are to walk alongside of the casket.

SUPPLEMENTAL DATA**Balcony**

Balconies are not generally recommended, especially in churches of moderate size, because those seated in a balcony tend to become isolated from the rest of the worshiping congregation. Balconies emphasize the spectator role of the worshiper rather than his participation in the service.

In larger churches a balcony is often a useful device for seating a greater number of persons within an effective radius for seeing and hearing.

If those seated in the balcony are to see the chancel it will be necessary to step succeeding rows up from the front. These steps should not exceed 6½ inches each in height, and the risers should extend across the full width of the balcony, including the aisles. The balcony should not extend out over more than two rows of the nave pews. There should be two separate sets of stairs to the balcony.

Candles

If the communion table is to be free-standing, the candles could be placed on a credence shelf on the rear wall of the chancel, behind the table;

but large candles standing free on the floor might be more in scale with the chancel. Candle splicers or joiners may be used, so that only the top part of the candle is burned and replaced when necessary.

Chancel Rail

There is a trend today to modify or eliminate the chancel rail in order to reduce or eliminate the effect of separation between nave and chancel. Its height is usually the same as the choir screen, approximately 36 inches.

Chancel Window

A chancel window facing the congregation, while it may be an aesthetically satisfactory solution, creates a problem of diverting attention from the cross and table to the window, or what is beyond the window. If it is a well-designed window it draws attention to itself. If it is clear glass, it could draw the attention of the congregation to a point outside the sanctuary.

Clear or lightly colored glass may create a problem of excessive glare which impairs the visual contact between the worshipers and the minister. Even the darkest chancel windows under certain conditions may be a problem.

If the intention of the church is to focus the attention of the congregation upon the liturgy and the physical symbols of worship, such as the cross, table, pulpit, etc., we question the desirability of a chancel window.

Credence Shelf

To provide a definite place for the candles, flowers, and/or empty offering plates, etc., we suggest an adaptation of the ancient credence shelf in the chancel. This shelf could be placed on the wall behind the communion table, and it should be large enough to accommodate the above pieces and high enough so that they can be seen by the congregation. The credence shelf does not replace the communion table but is an addition to it.

Cross

As late as 1920 the cross was unheard of in nearly all Protestant churches in America, but in a generation it has come back into almost general use. The problem today is not *whether* there should be a cross, but rather *how many* and *what size*. No church should have more than two crosses—one on the exterior and one in the chancel. The tendency to treat the cross as a decorative symbol to be used with abandon throughout the building is regrettable.

Flags

We do not recommend placing flags in the chancel for the following reasons:

1. We live in a day of growing stress on ecumenical Christianity. At the same time, our missionaries are hindered in preaching the gospel because Christianity has become so closely identified with western culture, "Yankee imperialism," etc. To correct an error of the past, it might be a wise and discerning policy not to permit flags (or any other secular symbol) to share the honor which attaches to the symbols of the Divine Presence.

2. Flags in the chancel create separate and static centers of interest in competition with the action of the liturgy and such essential physical centers as the cross, table, and pulpit.

3. Aesthetically, the colors of the flag often

CHURCHES, UNITED METHODIST

clash with the liturgical colors of the paraments and the chancel itself.

Hymn Boards

Hymn boards have been used to indicate to the congregation the numbers of hymns to be sung and the responsive reading for the day. Since nearly all churches now use a printed bulletin to give this information, we feel that hymn boards are no longer necessary. They cost money, and like the flags, create unnecessary centers of interest.

Lectern

The pulpit, table, and font are all that is needed for worship in most of our churches. There are times, however, when it may be advantageous to have a small portable lectern. Some ministers prefer to reserve the pulpit for preaching only, and use the lectern for the reading of the Scriptures, etc. This leaves the pulpit bookstand free of a large pulpit Bible, more easily usable for sermon notes or manuscript. Announcements and addresses or talks other than sermons are delivered from the lectern. Also if more than one minister is involved in the service, an additional place from which to speak or conduct the service may be helpful.

Offering Plates

Apparently there are two basic ways of receiving the offering. In most cases the offering plates are in the chancel and the minister hands them to the ushers who come forward to receive them. In other churches the empty offering plates are kept at the rear of the room and are brought forward by the ushers, only after the offering is taken. In any case, empty offering plates should never be placed on the table. After the offering has been received, the minister or ushers places the plates upon the table. If the empty plates are kept in the chancel we suggest that they be placed on the credence shelf, or on a small table provided for that purpose.

Organ Grille

If the organ pipes are located prominently on the chancel wall (so that they would become the visual center of interest if left exposed), we recommend that the pipes be screened from view by an organ grille. The screening material should be acoustically transparent. If an electronic organ is used, the grille will conceal the speakers and other electronic equipment. Exposed pipes are acceptable on side walls or at the rear.

Pews

If pews are used, provide for a center aisle and two sections of pews. Local building codes may specify the width of aisles and the seating space per person. We recommend side aisles in all but the smallest churches so as to provide direct access to both ends of the pews. On special occasions when additional seating space is needed, a row of chairs can be placed in the side or cross aisles, providing the local fire regulations are not violated.

Unless local ordinances require otherwise, allow a maximum of 14 persons per pew when both ends open out onto an aisle, and a maximum of 7 persons per pew when there is access to only one aisle. For pews to seat up to 8 persons the minimum pew spacing is 32 inches back-of-pew to back-of-pew. For pews to seat 9, 10 or 11 persons allow 33 inches and for 12, 13 or

14 persons per pew allow a minimum spacing of 34 inches.

Width of seat per person:	18" minimum 20" good 22" excellent
Spacing of rows of pews:	32" minimum 34" good 36" excellent
Spacing of screen in front of first pew:	36" minimum 38" good 40" excellent
Height of seat above floor:	17"

Aisles

Center aisle minimum requirements:	4' small church 5' medium church 6' large church
Side aisle minimum requirements:	2'-6" small church 3'-6" medium church 4'-6" large church
Front cross aisle minimum requirements:	5' small church 6' medium church 7' large church
Rear cross aisle minimum requirements:	4' small church 5' medium church 6' large church

Prayer Desk

A prayer desk (prie-dieu) provides a place for the minister to kneel. Since it is portable, it may be placed in front of the clergy seat or out in the chancel in front of the table. Here it is sometimes used for the wedding service. It should not compete with the more important liturgical centers.

Predella

The predella is a raised floor area or platform beneath the communion table. It is usually 6 inches or so higher than the rest of the chancel floor. Its function is to elevate the table so that it can be seen by the entire worshipping congregation. Many planners forget that virtually everything below head height (approximately 48 inches) will be masked from view by the heads and shoulders of people seated in the first few pews in the nave.

There should be a minimum of 36 inches and preferably 42 inches between the edge of the table and the edge of the predella. In larger churches 48 inches is desirable. This allows ample space for the officiating minister to present the offering or administer holy communion.

The steps leading up to the predella and/or chancel should be broad, 14 to 18 inches in width, with 6-inch risers.

Reredos and Dossal

The reredos is a vertical screen of wood or carved stone in back of the altar, usually ornate in design and intended to enhance the appearance and focal importance of the altar. The reredos developed in the Middle Ages as a successor to the ciborium when the altar was moved to the rear wall of the chancel.

Since we recommend a free-standing commu-

nion table, not an altar, the reredos becomes a distraction and an unnecessary item of expense.

The dossal is a fabric hanging on the wall in back of the altar or table. Like the reredos, its purpose is to give visual prominence to the worship center and its appointments. In fact, it is in fabric what the reredos is in carving.

The main disadvantage of a dossal (beside the danger of drawing attention to itself) is that it creates a large sound-absorbing surface in an area where you would normally want a hard surface to reflect sound out into the nave. We do not recommend its use.

FELLOWSHIP HALL UNITS OF VARIOUS SIZES

A Fellowship Hall and Lounge Seating Approximately 100 (70 + 28)

The floor plan below (Fig. 5) illustrates how a small fellowship hall may be used as a first unit for a congregation expected to eventually number 300-350 persons.

Space for dining in this building:

70	at tables in the fellowship hall
28	at tables in the lounge
98	total seating capacity

Assembly seating for worship:

81	in the temporary sanctuary
10	in the choir
32	overflow seating in the lounge
123	total seating capacity

Church schoolroom assignment and capacity:

Kitchen:	5	Younger children at 30 sq ft per person
Lounge:	17	Elementary children at 25 sq ft per person
Fellowship hall rear	20	Youths at 20 sq ft per person
front	28	Adults at 15 sq ft per person
up to	70	Total average attendance

A Fellowship Hall-Lounge Unit Seating Approximately 200 (144 + 48)

The floor plan in Fig. 6 shows a somewhat larger fellowship hall for a congregation eventually expected to number 700-750 persons.

Assembly seating for worship:

66	in the temporary sanctuary
16	in the choir
110	overflow seating in the rear of the fellowship hall
66	additional seats in the lounge
258	total seating capacity

Space for dining:

144	at tables in the hall
48	at tables in the lounge
192	total seating capacity

Church schoolroom assignment and capacity:

Kitchen:	15	Younger children at 30 sq ft per person
Lounge:	26	Elementary children at 25 sq ft per person
Fellowship hall rear	36	Youths at 20 sq ft per person
front	55	Adults at 15 sq ft per person
up to	132	Total average attendance

CHURCHES, UNITED METHODIST

Fig. 5.

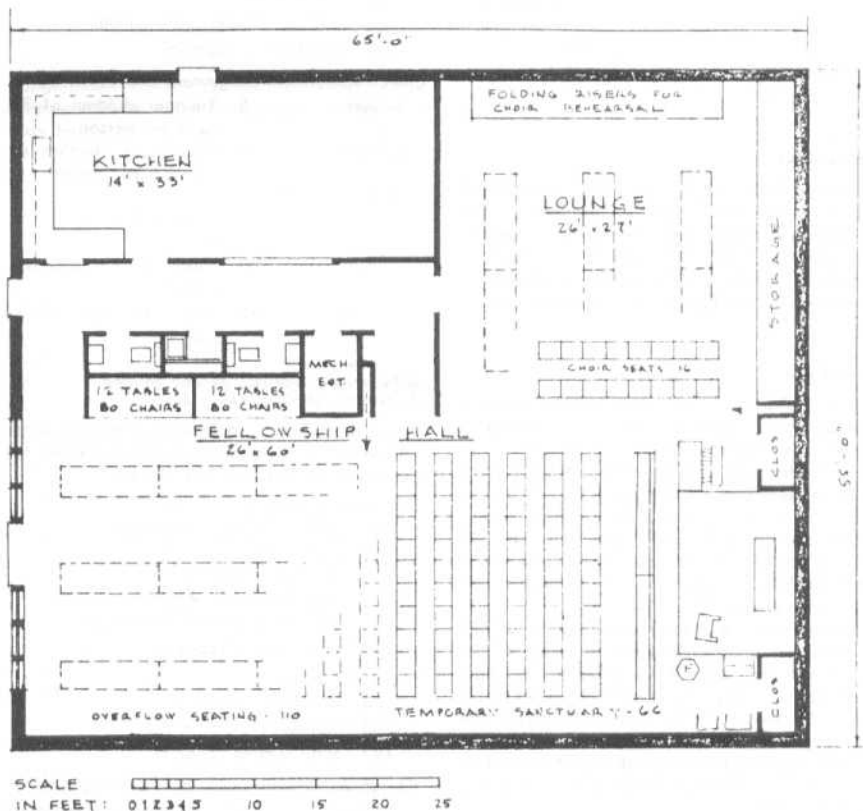

Fig. 6.

UTILITY, SIMPLICITY, FLEXIBILITY AND INTIMACY

In planning buildings designed to meet the needs of present and future generations, it is questionable whether we should continue to treat worship as something apart from the rest of life requiring a special place for this sole purpose. This approach presumes that all other activities are secular in nature and must take place elsewhere. In practice this has led to the building of one room for worship and other rooms for education, fellowship, or community services.

The early Christian church apparently made no such distinction. Homes were used for formal rites as well as a full range of domestic activities. A church building is essentially a house to permit the Lord's people to gather for worship and witness. The building itself is neither sacred nor holy. It is only the relationship between people that can be considered in these terms.

In addition to the more important question of what activities may take place within the church, the demand for adequate facilities for both new and old congregations in the inner city as well as in suburban and rural areas, places a heavy burden on funds available for building. In many instances it would be better to invest financial resources in program and additional trained personnel rather than continue to build single purpose structures.

At a recent meeting of the Commission on Worship it was suggested that churches be planned around the following axioms:

Utility A church should be designed for the several types of worship which will be used.

Simplicity Concentrate on the essentials and eliminate the superfluous.

Flexibility A church should be adaptable for many different services and occasions.

Intimacy Our buildings should foster a sense of oneness in the doing of our work.*

The sketches in Fig. 8 illustrate ways of accomplishing these means. Apparently maximum use can be made of a rectangular room with a level floor. Not shown in the sketches are such facilities as narthex, sacristy, organ space, choir room, kitchen, or storage areas which would normally be needed. The size and location of these spaces would vary with each architectural solution. To change the character or atmosphere of the room, movable wall panels, light cloth hangings or other devices might be used. The following abbreviations are used:

- T = Communion table
- P = Pulpit
- L = Lectern
- F = Baptismal font

* Professor James F. White in paper prepared for the Commission on Worship, Dallas, Texas, April 11, 1967.

CHURCHES, UNITED METHODIST

A. This arrangement for maximum seating at table in the Fellowship Hall shows 192 places with 72 additional in the lounge—or 264 total. If tables are placed perpendicular to the platform, the diners will have maximum visibility of an after-meal speaker or program. Tables for 8 are shown. Per person, this is the least expensive size and the one most commonly used. Storage: At (a), tables and chairs for hall; at (b) are tables and informal furniture for the lounge, scouts' storage; at (c) recreational equipment, speaker's stand, drama props, etc., for platform use, and materials for the adult classrooms (see arrangement K following).

B. Tables for 6 are better—they place everyone in conversational range. They are also lighter to handle, more flexible in usage; but they are slightly more expensive (about 8 percent). We recommend the smaller size, if possible. In this arrangement, the hall holds 120, comfortably seated. The lounge is shown arranged as an assembly and waiting space for diners, with desk for tickets, coatrack brought in from other area, and chairs. The piano could furnish dinner music or be used later in leading singing. Storage: At (a) 24 tables for 6 with 120 chairs over; at (d) is space for choir robes, recreation equipment, schulwerk [sic] or rhythm-band instruments.

C. Round tables (48-in diameter) seat 6 comfortably or will accommodate 8. They are best for placing diners in face-to-face contact, and they cost slightly less than the 8-ft rectangular tables. At 6 per table, the arrangement shown seats 156; at 8 per table, 208. In the lounge, informal furniture about a fireplace provides the living-room atmosphere which many churches desire. Storage: at (a) there is space for 36 round tables or carts, 120 chairs over, and church-school or recreational materials in the extra closet; at (b), additional tables, lounge furniture, etc.; at (c) and (e), materials for classroom and platform use.

D. Here the tables in the Fellowship Hall are arranged in a conventional U shape, for a banquet of 100-plus diners. The lounge area is cleared of all furniture, etc., for a scout meeting, with flags and backdrop on one side and stations for a relay race at the ends. Storage: At (b) a 5-ft-square [area] is enough for most scout troops. There is also space for furniture, etc. If needed later, the right-hand wall could become a storage area (for choir robes, instruments, special equipment, etc.). Note that by drawing the accordion-fold partitions separate groups could (at least theoretically) dine simultaneously in each of the three areas.

Fig. 7 Seating arrangements for optimum use of a Fellowship Hall.

CHURCHES, UNITED METHODIST

E. In this sketch, the hall is arranged for the showing of a motion picture. The screen is a pull-down installation on the wall behind the platform. There are 288 seats for the viewers. The lounge is set up for buffet refreshments (coffee, a light meal, or more) after the program in the hall. The portable serving unit from the kitchen has been wheeled out into the lounge for direct service of hot food. Such a buffet setup could be used with or after dancing, games, or any meeting in the hall, or for a "covered dish" meal to be enjoyed at the tables in the Fellowship Hall.

F. In this sketch, the combined hall and lounge is [sic] set up as an MYP or Youth Club center or canteen. In the well-lit hall, markings for large-scale recreation (volley ball, four-square, and shuffleboard, etc.) are shown in the flooring. Table games like skittles, table golf, or Ping-Pong could be included. Recreation equipment is stored on the high shelf at (a) or in closet (e). The dimly lit and more intimate lounge is suitable for small-group sharing. Pull-out partitions at (b) make several intimate boothlike groups possible. A demountable, prefab fireplace at (d) makes a larger conversation center. This and other equipment can be stored at (d) or (b).

G. Here, the platform has been set out into the hall for a theater-in-the-round or other event suitable for such a setup (string group, chamber music, dance, etc.); 210 people can be seated, none further than 25 ft from the stage. The lounge has been temporarily converted into "dressing rooms" with portable partitions rolled in from the church school. Special storage for the drama workshop (floodlights on stands, paint, tools, props, etc.) is shown at (b), opening into the corridor.

H. In this scheme, the platform has been set against an outside wall to permit maximum seating in the combined area (350 people plus). Two "entrances" for the performers are shown. The kitchen or some area of the church outside the Fellowship Hall wing could be used for "dressing." Storage for drama equipment is again shown at (b).

Fig. 7 (Cont.)

CHURCHES, UNITED METHODIST

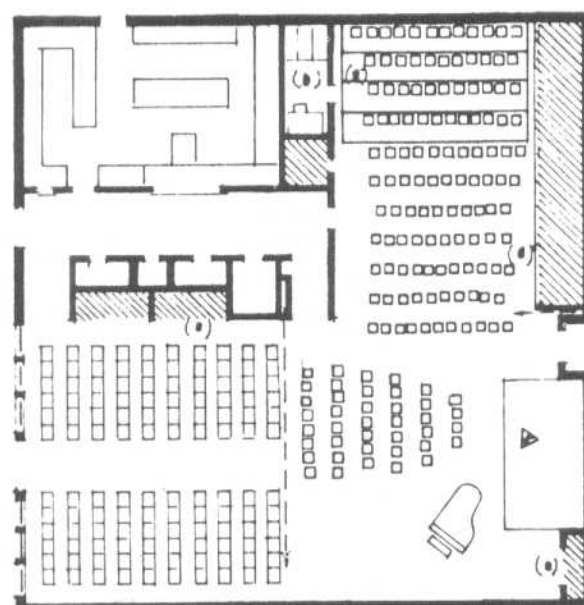

I. Here, the Fellowship Hall is arranged for assembly seating with no center aisle. Better viewing is possible using this system, since the choice center section is filled, but local regulations covering this arrangement must be carefully noted; 238 seats are possible. Incidentally, we do not recommend the use of pews at any time in this area of the church—all the indications are for chairs. The lounge is shown cleared of all furniture, etc., to serve as a waiting area, preparation space, or dressing room for the platform. A setup of this kind is suitable for a fashion show, for church-school "exercises," for a recital or musical program, for speaker(s), or drama. Center-section seating can also be provided for services of public worship, using the same chancel-platform setting as in J. We recommend a chair spacing of 18-20 in, and a row spacing of 36 in, back to back. Folding risers for choir at (c).

J. This arrangement shows the Fellowship Hall set up for public worship, as it would when the Hall is a first unit. The normal seating of 238 in the hall can be supplemented by overflow seating for 88 additional worshippers in the lounge. In churches which must also use the Fellowship Hall for church-school classes, the platform end of the hall could be prepared for worship beforehand, the rear of the hall closed off after class and set up for church while the front rows are filling. Divided seating as shown is suitable if the rows are too long for single-group seating. A 5-ft-wide storage area is shown at (d) for general use in the first unit. Later, this area, fitted with pull-out and turn-around racks like those used in department stores, could be used for choir robes.

K. This Fellowship Hall arrangement shows three church-school classes in progress behind the drawn accordion-fold partitions. In one, a circle of chairs brings the whole group into face-to-face discussion. In the next class, an audiovisual is being watched by small groups who will later form buzz-groups for discussion. The teacher stands beside the screen to aid in presentation. In the third room, a class seated in informal rows faces the teacher, his or her desk-table, and a map-stand or other teaching aid. For most churches, we recommend that these Fellowship Hall areas be assigned to adult classes, even though they be oversize rooms. In first-unit halls, it will be necessary to house the whole school in this area. And in first-unit churches, the kitchen will be only partly furnished (as in J), so that it could be used as a classroom too. Classroom storage for the separate groups will be at (a), (d), and (e).

L. In this sketch, the Fellowship Hall-lounge is shown in combined use as a music room. The rear of the Fellowship Hall is shown being used as overflow seating for the sanctuary across the narthex; 120 overflow worshippers may use this space, plus those who may sit in the narthex itself. If it is needed, the rest of the hall may be overflow seating space as well. A very large choir rehearsal is shown in progress in the lounge, which has been thrown open to the hall. Folding risers, usually seating all the choir or instrumental group in view of the director, now hold only part of the combined groups. The lounge is especially good for music use. Not only can it be made larger, but it is near rest rooms and can be separately heated or cooled. At (b), a small office for the Music Director is possible, with file cabinets and desk. At (c) are double chair-robe racks, rhythm-band or schulwerk [sic] instruments, etc.

CHURCHES, UNITED METHODIST

A. FORMAL WORSHIP

All furnishings are portable with the possible exception of the organ console. The emphasis is upon the pulpit, table and font. The nave seats 240 and the choir from 21 to 24.

B. BAPTISM

The pastor and the one being baptized would stand on the level of the chancel platform so the ceremony could be seen by the congregation. The parents and sponsors would stand before the font on the nave floor.

C. COMMUNION

Communion is served by the pastor to the congregation as they stand around the table. The center aisle has been eliminated and the rows of chairs placed 42" apart allowing 20" per person.

D. COMMUNION

The communicants are served by the pastor at a portable communion rail and kneeling step. The rows of chairs in the nave are spaced 32" apart allowing 18" per person.

E. COMMUNION

The communion table has been moved down into the nave with the congregation grouped around it. The pulpit has been moved to the center of the chancel platform. Communion could be served standing or the portable rail and kneeling step could be used for kneeling.

F. WEDDING

The width of the center aisle has been increased from 5' to 7' and the width of the front cross aisle increased to allow adequate space for the bridal party and pastor. A prayer desk or prie-dieu is used for kneeling. This plan seats 98 although the capacity could be increased.

G. FUNERAL

The width of the center aisle has been increased to 7' to allow the pallbearers to bring in the casket. The actual seating capacity would depend upon the need. The normal practice is to place the casket as indicated, perpendicular to the table.

H. RECEPTION OF MEMBERS

Those being received in membership are shown at the communion rail. The same arrangement would serve a confirmation service where kneeling is required.

Fig. 8.

CHURCHES, UNITED METHODIST

I. EVANGELISTIC MEETING

The congregation has been grouped together in front of the pulpit, which has been placed in the center of the chancel. The choir is grouped in back of the pulpit. The communion table and rail are forward of the pulpit.

J. CHOIR PROGRAM

The choir is grouped together on the platform facing the choir leader and congregation. Special choir programs (cantatas, oratorios, etc.) are popular in many parts of the country. There is considerable freedom in these plans in providing space for instrumentalists near the choir.

K. CONCERT

Ample space is available in this arrangement for large musical instruments and a piano on the platform.

L. DRAMA

The chancel platform serves as a stage for drama, interpretative dancing, church school pageants, etc. In this illustration, the organ console is screened from view.

M. DRAMA

The acting area is in the center of the nave and the chancel is used for seating. This is similar to theatre-in-the-round productions.

N. GROUP SINGING

For community or groups singing the congregation is grouped around the piano and the song leader.

O. AUDIO-VISUAL

The screen is located on the platform so that the majority of the audience would be within the recommended 60° viewing angle. Beyond this angle the picture becomes distorted.

P. MEETINGS

In this illustration two tables have been placed in the center of the platform with the leaders seated behind the tables. This could be used for debates, lectures or church or community meetings.

Fig. 8 (Cont.)

CHURCHES, UNITED METHODIST

Q. CHURCH SCHOOL

Three classes for youth or adults are shown in different parts of the room. We are assuming that separate classes would be provided for children.

R. STUDY HALL

The 40' x 65' room could also be used after school hours as a study hall. Separate tables are shown for each two to four students, as well as tables for those in charge.

S. DINING

Using standard size tables (30" x 96") the room would accommodate 192 persons allowing 8 persons per table. The 15' x 40' platform could serve for the speaker's table, additional tables or for a program.

T. DINING

If smaller tables (30" x 72") were arranged with space between each table, the room would accommodate 150 persons allowing 6 persons per table. If the tables were moved together to provide space for 5 additional tables, the room would seat 180 persons.

U. DINING

Round tables encourage a greater sense of fellowship since all persons are within conversation range of each other. This arrangement around 48" diameter tables seats 138 at 6 persons per table, or 184 at 8 persons per table.

V. DISPLAYS

The room is arranged for such displays as paintings, sculpture, book exhibits, schools of mission displays, church school exhibits or any other type of exhibition which requires space for large numbers of people and ample viewing areas. The arrangement is planned to encourage the flow of traffic through the exhibitions.

W. GROUP ACTIVITIES

If all the furniture in the rooms were movable, the entire area could be cleared for group activities. This would require ample nearby storage space for all furniture.

X. MINIMUM SEATING

The use of chairs allows the church to set up seats for the anticipated attendance. For each of these arrangements the room would appear to be full. (12 rows of chairs, 24" per person, 36" per row, seats 144).

Fig. 8 (Cont.)

CHURCHES, UNITED METHODIST

Y. AVERAGE SEATING

By reducing the spacing between chairs and between rows and by reducing the width of aisles, the room would seat 234 persons. (13 rows of chairs, 20" per person, 33" per row, seats 234).

Z. MAXIMUM SEATING

For those occasions requiring maximum seating the chairs are placed closer together. This will still allow ample seating space for most individuals. (15 rows of chairs, 18" per person, 32" per row, seats 300).

TEMPLES AND SYNAGOGUES

By KEITH I. HIBNER, AIA

Consultant: MYRON E. SCHOEN, FTA, Director, Commission on Synagogue Administration, Union of American Hebrew Congregations, and Central Conference of American Rabbis

GENERAL

Organized Judaism and the synagogue are found in nearly all of the civilized areas of the world except eastern Asia. Jewish culture, through the ages, has not developed an indigenous architectural style or expression primarily because Jews have been frequently denied social, economic, and educational opportunities, i.e., the owning of property and the establishing of permanent roots. Temple and synagogue designers have, for the most part, emulated regional architecture. Current congregations tend to welcome the best in contemporary architectural design and art work. The architect undertaking a temple or synagogue commission should become familiar with Jewish customs, traditions, art forms, and the magnificent literary expression of the religion.

Religious Judaism in the United States today consists of the Orthodox, Conservative, and Reform movements. Each group has readily distinguished ceremonial practices and a divergent approach to programming. Furthermore, within each of the three main divisions there exist considerable variations of viewpoints and practices. Hence, the architect will find it mandatory to collaborate closely with the individual synagogue building, religion, and education committees.

In the United States, the terms *temple* and *synagogue* are used interchangeably. This text will use the generic terminology *the synagogue*.

Site

If possible, the architect should advise on the selection of a site. Most community zoning and building jurisdiction will permit religious structures within any of their zoned areas. A site location on a secondary street at the approximate center of the congregation neighborhood is desirable. An optimum off-street parking ratio of one car per congregation family is desirable but seldom achieved. It should be noted that Orthodox congregations prohibit the use of autos or public transportation on the Sabbath and hence must be placed in close proximity to membership.

Materials

Since funds are usually limited, the majority of synagogues are designed for conservative initial cost. Construction materials and mechanical equipment should be specified for considerations of permanence, durability, and low cost of maintenance. The selection of better materials and equipment may increase initial cost but can result in considerable long-term maintenance economies.

Master Plan

Both budget limitations and anticipated congregation growth normally require a staged program and multiple use of facilities. An "ultimate growth" master plan should be designed so that the initial and later stages of construction can be readily expanded and integrated into the master plan (final) concept.

SPACE CRITERIA

Elements shown in Figs. 1 and 2 are those most commonly programmed in temple and synagogue buildings.

Worship Areas

Sanctuary. The sanctuary will traditionally, if site use permits, orient with the bimah platform to the east. The bimah platform height will vary from 24 to 36 in. Center steps (6-in. rise, 12-in. tread) are normally used. The focal point of the sanctuary is the ark, which is located on the rear wall area of the bimah. The ark cabinet houses the congregation's Torah—or Scrolls—the written doctrine of the divine rule for Jewish religious life. The ark platform is one or two steps above the bimah floor level. Suspended in front of and above the ark is the eternal light, which traditionally remains constantly lighted. Located on the bimah platform are reading lecterns for the rabbi and cantor, occasionally standing art work, and chairs for the synagogue officers and trustees. Note that all Orthodox congregations and some Conservative congregations separate the bimah area and the cantor's station from the pulpit area and ark. The specific requirements and physical facilities of the religious areas must be thoroughly programmed in the early design stage. The architect should seek advice from the rabbi and the congregation's religious committee.

Seating Data. Reform and Conservative synagogues commonly use the conventional fan or auditorium seating pattern with the bimah platform placed at the front end (preferably east). The Orthodox and Sephardic synagogues traditionally place the bimah platform in the center of the U-shaped rectangular seating pattern in the sanctuary. Men and women are seated in separate sections (usually divided by an aisle), and a more Orthodox group will require visual separation also between the men's and women's sections.

The number of permanent seats (pews) provided in the sanctuary is commonly 40 to 50 per cent of the anticipated ultimate adult congregation size. A synagogue with 400 to 500 members will provide 200 to 225 permanent seats (10 sq ft per person) for the average attendance at weekly services. However, the yearly observance of High Holy Days (Rosh Hashanah, the Jewish New Year; and Yom Kippur, the Day of Atonement) will require maximum seating (of several times more than regular attendance) with direct view to the bimah. Hence it is practically mandatory planning that the sanctuary seating area expand into multipurpose areas and social hall areas. Sliding or folding soundproof doors are commonly placed between the religious and social areas. Folding or stacking chairs (6 to 7 sq ft per person) are used for the temporary seating requirements.

Choir. Seating for the choir is usually in an area

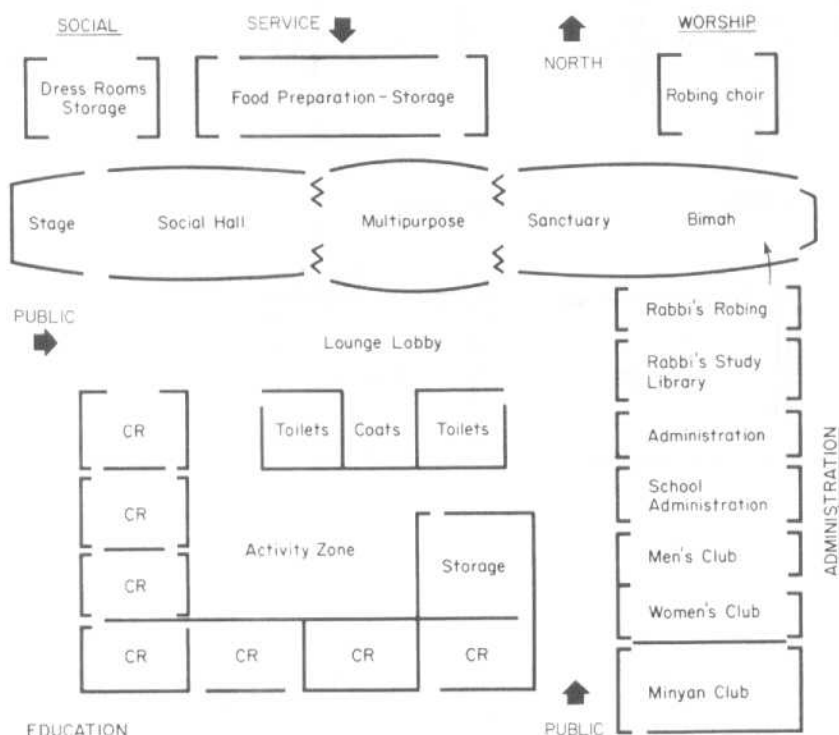

Fig. 1 Flow diagram.

Fig. 2 Plan for a reform temple. (Keith I. Hibner, Architect.)

TEMPLES AND SYNAGOGUES

concealed from direct congregation view. Movable screen partitions are utilized occasionally, so that the choir is visible for various functions such as weddings. The choir members and the organist must have a direct and easy view of the cantor and rabbi. Men's and women's robing rooms should have direct hidden access to the choir seating area or loft.

Minyan Chapel Such chapels are used for small groups—10 to 25 male congregants—for daily religious observance. Frequently a multipurpose area will suffice for minyan services where budget does not permit separate facilities.

Education

The Hebrew school normally functions in the late afternoon, after the public school sessions. Classes are ideally limited to from 15 to a maximum of 20 students. Normal public school desk and seating data apply to classroom size. Ample storage and display areas are required. Classrooms can also double as meeting rooms for adult game/craft clubs and education in the evenings. A teen-age or secondary social area is desirable and should include a small kitchenette facility. Outdoor supervised seminar and play areas are desirable.

Social Areas

Multipurpose Area Such a room is desirable when budget and space permit. The area is located between the sanctuary and a social hall and will open by means of movable doors to one or both adjoining rooms. The multipurpose room serves for overflow sanctuary seating or for larger social functions. Also, of course, the area is frequently used as a smaller social meeting room. The multipurpose area acts as an effective sound barrier between the chapel and social hall. A small kitchen unit for serving coffee and snacks is often incorporated.

Social Hall This area is used for larger social functions, i.e., dining, dancing, Bar Mitzvahs and wedding parties, little theater productions, and temporary seating for High Holy Day religious services. Storage space for folding chairs and dining tables is normally provided under a stage.

The stage should have a minimum area and facilities for amateur theatrical productions. A minimum depth of stage is 18 ft. A proscenium width of 24 ft is satisfactory. Minimum wing space is 10 to 12 ft. Overhead facilities for stage drop and lights should be provided. Small dressing rooms and toilets for men and women should be located backstage. The stage area platform is used also for High Holy Day seating.

Kitchen Requirements for the kitchen facilities vary greatly in individual synagogues. Smaller congregations will program minimum cooking-serving areas for use with off-premises catering establishments. Larger congregations will require a large self-contained food preparation center. The Orthodox and Conservative synagogues mandate kosher kitchen facilities with absolute separation between meat and dairy food functions.

It should be noted that many large synagogues will rent their kitchen and social hall facilities to an outside professional caterer, who will, in turn, operate the premises and supply food for social affairs sponsored by the synagogue as well as outside groups. This arrangement provides an income to the temple

and assures professional, readily available service.

Administration Areas

Administration Office An administration office (150 to 170 sq ft) should have visual control over the main public entry. Desk and file space is required for one or two secretaries. The rabbi's study is normally contiguous.

General Office A further general office (175 to 200 sq ft) is desirable. It includes the school administrative area, desks and counter for mailing and general filing, and storage facilities. A separate but adjacent soundproof room is desirable for mimeographing, mailing, etc. The school administrative portion of this general office should be so located as to have visual control of the classroom facilities area.

Rabbi's Study A room should be provided (175 to 200 sq ft) for lounge and seating space for small informal meetings, rabbi's desk or work table, and adequate shelf and storage facilities. The rabbi's study should have nonpublic access to a robing room and private toilet. It is most desirable that the rabbi be able to robe and enter directly to the rear or side of the bimah platform in the sanctuary without walking through the sanctuary's public seating aisles.

Library A room (220 to 250 sq ft) for the housing of religious books is required in many programs. The library is frequently used for synagogue executive board meetings. Furnishings normally include a table seating 12 to 16 and informal lounge facilities. The library should have access from the rabbi's study and the public lobby.

Men's Club and Women's (Sisterhood) Club Offices When required, provide (120 to 150 sq ft) room with desk and file space and seating for club officer meetings.

Miscellaneous Areas

Bride's Room This area (120 to 150 sq ft) is used for seclusion and final dressing of a bride prior to a wedding. A private toilet should be provided. It is desirable to locate the bride's room adjacent to a multipurpose room where the bride may receive well-wishers.

Public Toilets In a modest budget program, one set of toilet facilities can reasonably service the school as well as the sanctuary and social areas and hence should be easily accessible to both. This is possible because educational, religious, and social functions do not normally occur simultaneously. If budget permits, two separate toilet facilities should be programmed.

Coat Room Spaces for coat hanging and shelving should be provided (100 to 150 sq ft of floor area is adequate).

Public Spaces Lobbies, corridors, and circulation should be designed for direct, easy movement. Large lounge and congregating areas are required for social functions as well as religious recesses. Where possible, outdoor courtyards, terraces, and atriums are most desirable.

Storage Areas Ample storage space should be provided within the area of the separate synagogue functions (education, social, religious, kitchen, etc.). Provide storage area for the out-

door functions (deck chairs, lawnmowers, landscaping tools, etc.).

Mechanical Equipment Areas The location and size of rooms having utility services, heating, and air-conditioning equipment will be determined from criteria supplied by the mechanical engineering consultant. Exterior as well as interior access to these areas is desirable.

ADDITIONAL DESIGN CONSIDERATIONS

Landscaping

A landscape architect should be retained as a member of the planning team. Hardy, easily maintained shrubs and plantings should be specified. Service areas should be screened. Care should be taken to incorporate landscaped areas for congregation use in the outdoor celebration of the festival holidays, i.e., feasts of Shabbath and Sukkoth.

Aesthetics—Art Work

Nineteenth-century American synagogues were predominantly routine copies of churches. The meaningless six-pointed star (Mogen David) was the distinctive (typical) form of art decoration. Today, however, architects and artists are making significant contributions to Jewish culture by incorporating Jewish religious symbolism in structure and ornament. Ideally, the religious artist will work under the direction of, and collaborate closely with, the architect. The artist should be retained in the preliminary planning stages. The art program will include such items as decorative ark doors, the design of the eternal light, stained glass windows, exterior and interior lettering and sculpture, woodcarvings, weavings, lecterns, choir screens, paintings, mosaics, etc. While Jewish tradition still leans strongly to the omission of the human face or form in the sanctuary and strictly prohibits the depiction of the Deity in any form whatsoever, there has been a decided return to the human and animal form in art work in contemporary buildings.

Mechanical Design

The master plan criteria of staged construction will necessitate careful consideration by the mechanical engineering consultants; i.e., electrical service or heating and air-conditioning plants may be oversized to accommodate future requirements. Economical heating, ventilating, and air-conditioning design will utilize multi-zone operation consistent with time-staggered synagogue facility use. A checklist prepared by the architect will include detailed design criteria for multiple mechanical building facilities. These will include exterior, interior, and stage lighting requirements; acoustic considerations; fire alarm systems; intercom and public address sound systems; kitchen design; pipe organ installation; fire hydrants; in-ground sprinkling system; design of toilet facilities and exterior ramps for the handicapped; site and building drainage, etc.

Information Sources

The most knowledgeable and comprehensive source for synagogue design information in the United States today is the Commission on Synagogue Administration of the Union of American Hebrew Congregations, 838 Fifth Avenue, New York, N.Y. 10021. A list of their books and publications is available on written request.

By RICHARD M. BENNETT, FAIA

THE SOCIAL CENTER

The three principal functions of the synagogue are to provide a place for worship, a place for education, and a place for the Jewish community to carry on some of its social activities. The latter function—the community function—is what makes the synagogue such an unusual religious building.

It is fair to say that the extent to which a modern synagogue fulfills that community function will determine whether the congregation thinks of its building as a symbol of a *living* religion or whether the building and the activities within it will seem divorced from the realities of everyday life.

The community or social functions of a synagogue have always constituted one of its main purposes. Certainly, the outer courtyards of Solomon's Temple served a visiting and meeting-in-fellowship need. There, too, one found chambers for the preparation of food, and special rooms for those with special interests. History also shows us that subsequent synagogues were true community centers in that they were built around a congregation and its needs rather than centered upon a royal priesthood. Even beyond areas for the immediate use of its members, the synagogue had rooms for the reception of travelers who paid for such hospitality many times over with their tales of foreign places and news of the outer world.

So the importance of the synagogue as a community center is not a recent development. Only its ways of serving the community are modified—the purposes remain unchanged. The basic need is for a place for friendly, social intercourse; a place to discuss common day-to-day problems in the outer world; a place for healthy common activities, for the young folks to meet and to prepare to assume their places in the community; a place to enjoy the company of those with the same interests; and, finally, a place in which, from time to time, one might be stimulated by considerations beyond the immediate horizon.

Today, these fundamental needs are reflected in the increasing complexity of synagogue plans. Spacious corridors, foyers, and lobbies have taken the place of the ancient open courtyards. There are club rooms for men, women, and children. There are kitchens for the preparation of food and large spaces for dinners and suppers. There are areas for dances, plays, lectures, concerts, and exhibitions. There are classrooms for adult education as well as craft and hobby rooms. And there are offices where the organization and direction of these activities can be guided and publicized to ensure their success.

Naturally, there is a tremendous range in the size and extent of the facilities provided depending upon the size and means of each congregation. Few synagogues have a separate space for every function, and the multi-use of space is the rule rather than the exception.

Corridors and Vestibules

The most elementary social function is the meeting, greeting, and visiting with fellow con-

gregants before and after religious services. This requires generously sized corridors, aisles, lobbies, foyer, and vestibules. If these elements are generous in size, they permit friends to pause and talk without obstructing the flow of traffic. For the same reason there should be wide walks outside the building, and a large paved area or courtyard that invites "stopping to chat" without blocking sidewalks. A few feet added to a corridor makes it useful also as an exhibition space and does much to enhance the dignity and serenity of a structure.

The Social Hall

The social hall is probably the most important community facility. With a kitchen it becomes a banquet hall; adding a stage makes it a theater or lecture hall; removing chairs and tables makes it a dance hall or game room; by means of folding doors it can become overflow space to be merged with an adjoining sanctuary for High Holy Day services.

In determining its size one can estimate its capacity by allowing about 7 sq ft per person for seating on folding chairs in rows and about 12 sq ft per person for seating people at long tables. Main aisles from the kitchen to dining tables should be at least 5 ft wide and other spaces between tables can be 3 ft wide. Such approximate standards are useful only for preliminary planning, since each room becomes an individual problem which must take into account the position of entrance doors, the kitchen access, stage platform, exits, and so on. Careful attention to seating arrangements is most important in achieving quick, smooth, and efficient service of meals.

The height of the social hall is an architectural consideration. If the room is to be used for games, such as basketball, that may determine its height; if it is to be open into the main sanctuary through folding doors, the merger of these two spaces may be a deciding factor.

Sometimes there will be a projection room for movies; but the wide availability of 16 mm film, which is fireproof and does not require a professional operator, makes such an elaborate installation less necessary. If, however, a projection booth is desired, it should be large enough to make possible the use of color and spot lighting of the stage. Phone and buzzer connection to the stage manager is then essential. Even if it is planned for the use of 16 mm projectors or slides alone, a signal system and conduit connections for sound should be provided.

Plays and movies make light control of windows a serious problem. Windows might be eliminated entirely to escape this problem, but a frequent objection to that is that the same space is used for many different purposes and should therefore be capable of reflecting a number of different moods. The answer is that this can be accomplished effectively by several artificial lighting schemes. For example, one could have a down-light only from the ceiling for dances and lectures; light "washed" by wall brackets over ceiling and walls (and no other lights) for dining; and all the light fixtures turned on for games. Many congregations do not allow their social hall to be used for games

that are liable to give the room too much wear and tear. If the room is used for games at all, any windows will have to be specially guarded against breakage; and if large windows are used, care must be taken to have them screened on the outside by planting (or have them look out on an enclosed area) to ensure privacy from anyone passing by. So that, by and large, a good case can be made for a windowless social hall.

Here are some specific details that must be watched in planning the social hall:

- As in all public buildings, durability is a prime consideration in the choice of building materials. By using natural materials on which any scratches will uncover the same color (and more or less the same texture) as the original surface, one can make sure that a room will last longer and look better for a longer period of time than if one had used synthetic surface materials and unprotected plaster and paint.

- In a room that is to serve so many functions a rather neutral color scheme will make decoration for specific occasions a good deal easier and more effective than a strong initial decorating scheme.

- There should most certainly be some acoustic treatment to quiet the room, and the designer should investigate the acoustic properties of the room for its use as an auditorium.

- If the room has a large seating capacity, artificial ventilation is needed during some of the events that may take place in it.

- Generally speaking, a hardwood floor is recommended for a social hall.

- Among the drawbacks of multipurpose rooms—which must have level floors—are less comfortable sight lines for stage, lecture, and movie purposes.

The Stage

The stage itself can vary in elaborateness from a temporary platform at one end of a room to a complete professional setup. But in all stage designs there are certain basic principles that must be followed: The first is to augment the playing area (the part visible from the audience) with space at both sides for the exits and entrances of the players, for temporary placing of props and of scenery necessary for other acts, as well as for positions for stage crew and actors awaiting their part. Experience suggests that the horizontal handling of scenery is preferred for amateur theatricals. "Flying," the hoisting of backdrops and unused scenery, is expensive and relatively dangerous to untrained people. The stage floor should be of soft wood to allow for stage screws to brace the scenery.

A most vital element of the stage design is good, flexible lighting. Folding footlights, border lights above, and a method of lighting the entire proscenium from the front, coupled with heavy-duty outlets for spot and floodlights backstage, should all be included.

Dressing rooms are necessary—but sometimes Sunday school rooms must double for that purpose. Most needed is storage space. Old scenery, props, makeup material, stage braces, extra lights, should all have a space where they can be kept safely. It must be re-

TEMPLES AND SYNAGOGUES

membered that several different groups will probably make use of the stage—groups of different ages and degrees of responsibility. In such cases some groups should have space to keep their own accessories under lock and key.

No matter how elementary the stage setup, there will, of necessity, be some making of scenery with its attendant painting and mess. In other words, the stage should not be a "finished" space, but a workshop within which one can simulate a variety of environments.

If the auditorium is to be used for many different purposes, chair storage may be found under the stage. Most often the chairs are stacked on carts which can be pushed into position under the stage. This method requires the stage to be about 3½ ft above the floor. Occasionally, one or two sections of the stage floor can be made removable, but such a provision is not mandatory. Access from outside to the stage area must be considered in relation to the size of the scenery and props that will be used. This access should be convenient to a service drive.

The Kitchen

The layout should not be that of a commercial kitchen. A greater number of people will have to be accommodated; its use will be rather sporadic; and the kitchen help will not be so well trained to work together—which means that they will need more space than would be provided in a commercial kitchen.

The basic scheme for kitchens usually develops from the route waitresses follow in returning from the dining room. The planning sequence is for them immediately to pass a *soiled dish station*, behind which is the dishwashing equipment, and (if space permits) the dish storage. Next, the waitresses pass the cook's table which is backed up by ranges, ovens, space for meat and vegetable preparation, and storage, including refrigerators. They then pass a cold table where salads are prepared. At this station, ice cream is picked up—if that is the dessert. Next comes the pastry table where milk as a beverage is usually found as well. Finally the waitress passes by the coffee station.

The synagogue kitchen differs here from the usual commercial kitchen: first, all plates are served with the same menu; second, returned plates all come at the same time, but they do not need immediate washing for immediate reuse. This means there may have to be greater stacking area, but the dishwashing equipment may not have to be so elaborate or work so fast. Finally, attention to special requests is at a minimum, and each waitress need merely pick up plates and portions already prepared and waiting. Checking stations and cashiering can be dispensed with under this arrangement.

If at all possible, kitchens should be planned so that the entering traffic moves from the right to the left. The kitchen should be entered and left through vestibules which deaden the noise so that after-dinner activities in the social hall are not disturbed by the sounds of finishing up in the kitchen. Attention must also be paid to ventilating the kitchen, both to prevent odors from permeating the rest of the building and to ensure comfort for the volunteer workers. In smaller kitchen installations, pass-through openings may be used as pickup stations for the waitresses rather than having them file through the kitchen. A similar slot can be located for the return of used dishes.

Here are some additional points to consider in kitchen planning:

- * For congregations adhering to the dietary laws, separate dish storage is demanded, as well as separate sinks for washing the double set of plates.

- * Since the kitchen will be used by different groups of women, glass cupboard doors are often specified so that those unfamiliar with the kitchen can more readily find stored articles.

- * Cupboards should be planned for utensils, silver, paper cups and napkins, and linen storage.

- * Storage space should also be provided for canned goods, soft drinks and other supplies for special events, as well as lockers or clothes closets and toilet facilities for kitchen help.

- * Stainless steel equipment, quarry tile or greaseproof mastic floors, tile walls, and acoustic ceilings are recommended.

- * The kitchen should be close to a service entrance, which should give access to a screened, walled-in service court large enough to take care of the necessary refuse.

- * A telephone in the kitchen is a necessary convenience and should connect with the administration office.

- * In addition to the main kitchen, it is not uncommon to find kitchenettes for use at small teas and for the staff to use for their lunches. If a separate kitchenette is not used, a smaller stove for small occasions should augment the main range.

Parlors and Lounges

A parlor or lounge can serve many purposes. Teas, coffee and cake refreshments and visiting after evening affairs, club and committee meetings, as well as weddings and receptions need that kind of space. The relation of such a room to the rest of the temple is important.

Open and flexible planning does not conceive of a synagogue plan as a series of cells strung along corridors but as a series of large spaces that flow into each other. They can still be closed off one from the other whenever a desire for privacy or use by smaller groups makes this necessary.

The parlor or lounge should be near the main kitchen or near a kitchenette.

Changeable lighting effects for different purposes make the room more useful; furniture that can be shifted without too much difficulty is similarly desirable. If this room can be designed to open onto a patio, court, or garden, its charm and usefulness will be tremendously enhanced.

Club Rooms

Economy usually suggests that the same club room should be shared by a number of organizations. If that is so, individual closets, or even storage rooms, which can be locked up to enable each organization to store its own possessions, will give each the sense that its needs were considered in planning the building.

Craft Rooms

Art studios, photographic dark rooms, wood-working and sewing rooms, and the like are often used by both adults and children, day and night. This raises several problems: there must be storage space for materials and for projects under way; the rooms must be located in such a way that they can be used independently of the rest of the building; furniture suitable for both children and adults must be provided; there should be plenty of steady, clear light; they should have durable wall and floor finishes; they should be sound-conditioned to

keep their noise away from other rooms; and, in some instances, they should have special safety devices to prevent the use of dangerous equipment without adequate supervision.

Games and Sports

In the small synagogue, the social hall may, on occasion, be used as a game room. As noted above, such necessarily rough usage demands materials and details which are often not desirable when the room is used for more formal occasions. Ping pong and less strenuous (and destructive) games are then indicated.

In some cases basement space can be created quite economically and playrooms can then be located at half grade or below.

If a gymnasium is to be included it should be big enough to house a regulation-size basketball court. In addition to the playing floor, there must be a locker space, shower and drying rooms for both boys and girls, and storage space for equipment. While it is possible to build one gym for boys and another for girls (or to build one large gym that can be divided into two), a single gym used alternately seems more reasonable.

How to Publicize Community Activities

The office space of the synagogue must include space for those who organize, schedule, and publicize the community activities. Desk and work-table space, filing space, space for duplicating devices and for envelope stuffing and kindred tasks must all be provided. Often publicity is taken for granted in a small congregation, since it is informally accomplished by word of mouth. With expansion, this situation often changes and organized publicity is needed to get full advantage of the opportunities offered by a new building. In addition to this office space, bulletin boards in key spots, with adequate space for posters and notices and good illumination, are important. Display space for objects created in art, sewing, and craft classes also provide a stimulus for those taking part in such programs as well as encouragement for others to enroll.

Storage Facilities

Large closets in each room are often of greater value than large storage rooms somewhere else. Desk drawers, table pedestals, chests, and cabinets often turn out to be more flexible and cheaper than built-in equipment.

One of the vexing problems created by large community facilities is the disposition of hats and coats. Lockers that can line the corridors are probably best, though they are expensive. In more modest plans, hook strips and a shelf have proved to be perfectly satisfactory. A checkroom (supplemented by the use of classrooms for peak loads) offers another sensible solution. In classrooms, wardrobes whose doors open in unison have turned out to be usable. Sometimes the doors can have blackboards on their outer faces.

How the Community Function Affects the Overall Plan

The section of the synagogue devoted to community affairs should be located—and its various entrances should be arranged—so that it can be used independently of the rest of the building when necessary. This means, incidentally, that the heating and ventilating system can be zone-controlled to reduce operating cost. Any intelligent plan will group together areas of similar use.

TEMPLES AND SYNAGOGUES

As a principle this is obvious. But in practice there are a number of factors that must be remembered. Though the building may be divisible into zones according to function, each zone must have access to toilets. The office area probably should function in relation to each zone; and certain classrooms must be considered both as part of the religious school and as part of the community center. This is especially true of classrooms that may double as dressing rooms for the stage; of the arts and crafts rooms and the camera studio; and of classrooms that may on occasion double as coat rooms.

There is a natural temptation for a congregation to try to arrive at a fixed and final plan solution. Only rarely will we accept the fact that future generations may discover new needs—and may wish to abandon some activities we now hold dear. The wisest planning will allow for additions and make future changes easy. This is accomplished best by the elimination of interior bearing walls, by extending corridors to the full length of any wings, and above all, by starting with a site that will allow for healthy growth. For the community functions of the synagogue have grown and changed radically over the past centuries, and there is no reason to believe that this growth and change will not continue.

By MAX B. SCHREIBER and T. P. DEIS

THE EDUCATIONAL CENTER

In planning the educational facilities of a synagogue, several general considerations must be kept in mind from the very start.

Future expansion is one. This can be accomplished in several ways. One is by *horizontal extension*, i.e., either by increasing the size of the wing of the building or by constructing an additional wing. In this connection it is important to secure sufficient land at the outset so that there will be adequate space for the extension; or else, there should be an agreement whereby adjoining land may be secured when required. Future expansion may also be provided by *vertical extension* in the form of adding one or more stories.

While horizontal extension is usually more desirable than the vertical (since it reduces walking up and down stairs), it is frequently impossible to acquire the necessary land. In that case future stories can be planned by slight increase in the foundations and other supporting members. The additional cost is negligible compared to the resulting benefits.

The one-story educational unit is undoubtedly the best arrangement. It permits direct access to the exterior for outdoor play, with quick and easy dismissal in case of an emergency. If conditions require more than one story, then stairways must be introduced and there should be a sufficient number of stairs to permit quick exit. Usually, local building codes are very specific about the number and width of stairs required as well as their location, construction, and arrangement.

Children should not be required to walk more than two flights of stairs; therefore, the mod-

ern school must be limited to a three-story building. Only in extreme cases (where horizontal planning is impossible because of high land cost or for other reasons) is it permissible to build more than three stories—and that only if an elevator is provided. This of course is only a last resort since the elevator is expensive to install and costly to operate and maintain.

Great care should be given to the exposure of the classrooms. For the academic classroom an east or west orientation is desirable. Special rooms like nature study, science, should face south. The ideal exposures for the kindergarten or nursery are south and east.

Here are several specific questions that arise in the design of a synagogue school wing:

How Many Classrooms and What Size?

The size of the school, and therefore the number of classrooms, depends on the number of pupils expected to attend and also on the type of school. Classrooms for an all-day school will vary slightly in requirements from those for a part-time school. Since finances are of utmost concern to most institutions, the classrooms are frequently planned to accommodate a large number of pupils in order to reduce the number of teachers. But conditions vary from year to year, so that a large room may be wasted if only a small number of pupils will use it. Good education practice, on the other hand, dictates smaller classes for greater efficiency; between these two extremes a happy medium must be selected. A class of 25 pupils has proved satisfactory in most instances. Since most schools have shown considerable variation in the size of classes for different grades, it is often possible to construct classrooms of varying sizes to accommodate from 20 to 35 pupils.

The number of children to be provided for will depend largely on the community. A careful survey must be made to determine how many pupils may be expected to attend the school. From that figure the number of classrooms can be arrived at, using the average-size class as a basis. For an all-day school, provision must be made for at least one classroom for each grade in order to permit a full school curriculum.

The actual size of the classroom is based on a minimum of 15 sq ft for each child. This figure provides only for the area devoted to seats and aisles; if the educational program calls for activity space, then the room must be based on a larger amount of between 20 and 25 sq ft per child.

The advantages of the larger room can readily be understood. With it an air of informality and spaciousness can easily be achieved. From nearly every point of view it permits greater flexibility in use. It provides increased flexibility in the arrangement of furniture and class groups; in the accommodation of changing class sizes; in the education program which can be carried out in the classroom; and in the accommodation of adult activities.

On the other hand, the special suitability of the smaller room for the work of small groups and committees should not be overlooked.

Movable Partitions in Classrooms: Pros and Cons

Various types of movable partitions may be used to separate one room or area from another. One type becoming increasingly popular is the folding partition which extends or closes with ease and operates in a fixed track. A second type is the wood accordion door—which is hinged so that it may be extended to form a wall or folded back out of the way

against opposite walls. A third type is a curtain of cloth, reed, or bamboo, operating in or on a fixed track. A fourth type is the movable area separator, which is really a portable screen generally extending to a height of 6 or 7 ft. Finally, a partition might be made in modular units in such a way that these can be disassembled and moved to a new location. This last type probably is not a movable partition in the narrower sense.

Multiple Use of Schoolroom

Most of the factors mentioned in the two preceding sections, such as the size and flexibility of classrooms, have a direct bearing on the extent to which classrooms can be used for multiple purposes. If there is no large assembly hall or auditorium available, a row of classrooms separated by folding or accordion type doors can quickly and easily be converted into a large assembly, meeting, or banquet hall. A smaller classroom, however, accommodates the smaller group or committee admirably. In this way, both large and small classrooms can serve subsidiary uses such as for meeting, working, and social gathering places.

In the dual use of a room, the selection of the type of furniture is of utmost importance. If a classroom is also to be used as a meeting room for adults the *fixed* type of children's desks and seats will be impractical for the adults. It will be necessary to select the upper-grade classroom to be used for adult meetings since there the furniture will be of a larger size and more suitable.

For the afternoon type school, a large space must be set aside for the pupils to gather in inclement weather before time for classes; this is required since the classrooms may be occupied by a previous session and the pupils will not be able to go directly to their classes until the previous period is ended. In the all-day schools the problem does not generally exist, since the pupils can go directly to their classrooms.

The Kindergarten as a Nursery

A kindergarten and nursery can be a powerful force in attracting younger families to the synagogue who otherwise would be unwilling to leave their small children at home or who could not otherwise all attend at the same time. The kindergarten and nursery may well be combined; in fact, there is a worthwhile advantage in this. In the case of families with two or three children in the nursery and kindergarten age group, keeping them all together helps them adjust much more quickly to the new surroundings, cuts down the fears and insecurities which children naturally feel under the circumstances, and makes the work of the adult attendant much easier.

This kindergarten area should be well sound-proofed. Consequently, a movable partition separating this room from another might be inadvisable.

The room should have adequate tackboard area for mounting large, colorful posters and displays. For the smallest children, and for those who become sleepy, the necessary number of cots should be provided.

It is important that the kindergarten and nursery be large and roomy. Children of the age to be accommodated here often play on the floor and delight in active games. These demand generous space. Adequate room is needed for the storage of toys, materials, and other play equipment. From a health point of view, congestion in this space particularly ought to be avoided because it encourages the

TEMPLES AND SYNAGOGUES

spread of disease. In general, it can be said that an air of attractiveness and commodiousness in the nursery and kindergarten area will return worthwhile dividends in increased family attendance and participation in all the activities of the synagogue.

In order to provide as much sunlight as possible, the kindergarten room should face south and east. The ideal location is on the first floor to avoid steps and also to provide easy access to an outdoor playground, which is of utmost importance to this kind of a class. *The area of this room should be based on 30 sq ft per child and the class should be limited to a maximum of 20 children.*

Window areas should be generous—the more light the better. If the windowsills are more than a few feet above the exterior ground, some type of window guard must be provided to protect the youngsters from falling out. Windowshades are necessary, since the kindergarten pupils frequently rest during the day and require a darkened room. Also the heat of the sun and strong glare can be minimized by lowering the shades.

Since the kindergarten pupils must be kept under constant observation, it is mandatory to provide the toilet room directly off the main playroom. In this way the teacher can control the children and help those who require assistance without leaving the room itself. At least two water closets and two washbasins should be provided in each kindergarten toilet room, and these fixtures should be of the small, low type to suit the age of the children. Soap dispensers and paper towels are provided for purposes of cleanliness and to teach the children good health practices. A wash sink in the playroom itself is standard equipment, since children love to play with water. Drinking facilities must be provided either in the form of a drinking fountain or by means of paper cups adjacent to the sink.

Clothing facilities should be located in the playroom itself or as close to it as possible. The cubicles containing five or six spaces have proved quite satisfactory since they are easy to move from place to place. The top portion of each section is devoted to a blanket or hat, the center portion is for the coat, and the lower part for rubbers or boots.

There should be a sufficient number of movable toy storage cabinets. These cabinets are used not only for the storage of toys and equipment but also to form alcoves of varying sizes and shapes to section off various play activities. Since the children play on the floor a good part of the time, a sanitary material must be provided which is easy to clean, warm to the touch, and colorful.

While many of the rooms in the education center may be used for other purposes, the kindergarten should never be used for any other purpose. Frequently, the children work on a project of building which may take several days or a week, and this must not be disturbed.

In connection with the kindergarten room, an outdoor playground is necessary since the children spend considerable time outdoors in good weather. Sand pit, swings, slides, seesaws, are the commonly used items of equipment. The playground should be so arranged that the sun will strike it and not be cut off by adjoining buildings.

Design and Furnishing of a Classroom

Research of late years has established that the planning of physical environmental factors of the classroom—such as seating, lighting, decoration, temperature, and sound—contributes greatly to the learning progress and well-being of the children. Coordinating the environment in this way is particularly important where the children spend several hours in sustained visual activity.

The proportions of an academic classroom should be such that the width is about three-fourths of the length. The long, narrow room provides better control for the teacher than a classroom which is wide and shallow. In the latter room the light from the windows will not penetrate to the far side and thus the last rows of seats will be poorly lighted. The windows should be arranged on the long side so that when the pupils face the front of the room the natural light will come from the left side.

Windows may be as large as possible, starting at approximately 3 ft above the floor and rising to the ceiling or as high as structural members permit; the higher the heads of the windows the farther the light will penetrate toward the opposite side of the room. The areas of the windows should never be less than 10 percent of the floor area of the room. Shades or other sun-control devices should be provided to cut the glare and strong sun and for use if motion pictures are shown.

The following description of a typical classroom should not be taken as a rigid formula, for many variations in design are possible. This is merely one good way of designing such a room: the front of the classroom should be provided with a chalkboard across the entire wall, with a cork tack board above. On the corridor wall toward the front of the room is the door. This door should swing into the room if the local law permits, in order to keep the corridor clear. If the law requires that the door swing outward towards the corridor, then it should be set back into the room in the form of a recess. The door itself should be provided with a glass vision panel, and a glass transom should be provided over the door to admit light into the corridor. On the room side of the corridor wall, beginning at the entrance door, there should be a series of cabinets in this order: teachers' locker, storage cabinet, pupils' wardrobe, material cabinet, exhibit cabinet with a cupboard under, magazine rack. The wardrobe is composed of a series of doors which contain tack board or chalkboard sections. The Austral type wardrobe doors are the most acceptable since they pivot out of the line of travel; they are, however, the most expensive, and if finances are limited, then the sliding or hinged type of wardrobe doors may be used. Within the wardrobe are hooks and a shelf for hats. The wardrobe compartment must be ventilated, either by mechanical means if the building is equipped with an air-conditioning or ventilating system or by means of a grille in several of the doors.

Two types of flooring are generally used in classrooms: the wood floor and the asphalt tile floor. With fixed furniture, the wood floor must be used to provide a surface for fastening the desks and seats. The tendency in modern education, however, has been toward movable

furniture, and in that connection asphalt tile has proved most satisfactory.

Classroom furniture of the best design and quality is available at moderate cost. Since the equipment will be moved frequently, it is important that it possess the needed strength and durability. The soundest equipment for individual student use is a desk with swivel seat and a top adjustable to 20° slope. Depending on the extent to which the room is to be used for different purposes, individual tables with sloped tops and separate chairs provide greater flexibility. These individual tables can easily be grouped to form larger working surfaces. Probably the greatest all-round flexibility can be achieved by the use of larger multi-place tables with adjustable-height steel standards and folding chairs. For kindergarten and primary grades, however, folding chairs are not satisfactory.

Painting the classroom does more than any other single item to make the room attractive and cheerful. The painting scheme should produce high reflectivity without glare and yet maintain the practical quality of easy maintenance.

Adequate artificial overhead light should be provided to supplement daylight and for evening activities. At least one electric outlet must be provided for showing moving pictures and for similar purposes.

The Library, Visual Aids, etc.

Depending again upon the scope of the services the synagogue means to offer, it can provide files of periodicals, newspapers, motion picture films, and recorded music, which might not otherwise be conveniently available to members.

The library might also be made available for small meetings, teas, and receptions.

Beauty and attractiveness are just as important as health and usefulness in planning the library. Informality without loss of discipline can be obtained by the proper selection of furniture, equipment, and decoration. The shelves must be suited to the age groups for which they are intended. Best possible natural daylight should be obtained and bilateral fenestration is desirable. Artificial illumination must be carefully worked out. If the library is to be used by outsiders after school hours, then the room should be located in such a position that it is easily accessible from the exterior; yet it should be removed from the noisy side of the building.

Modern education is making more and more extensive use of visual aids in an unending variety of motion picture films, slides, maps, charts, photographs, and other non-book aids. These items are usually controlled by the school library and are made available for use in such a manner as has been traditionally employed for books. Special provision must be made for storing and handling the items mentioned and cabinets and shelving or special racks are required. The circulation and storage of records and portable record players and radios also come under the jurisdiction of the library.

CHURCH SCHOOLS

By MILDRED C. WIDBER and SCOTT TURNER RITENOUR

TABLE 1 Rooms Needed in Relation to Program and Size of Church School—Through Sixth Grade

	Very small church school, 1-99 pupils		Small church school, 100-199 pupils	
	Enrollment	Housing facilities	Enrollment	Housing facilities
Nursery, infants and toddlers under 18 months		None unless separate space is available.		None unless separate space is available.
Toddlers, ages 1½ and 2		Same as above.		Same as above.
Nursery class, age 3	12	May be necessary to house several 3-year-olds in same room as kindergarten. Try to keep in a separate area of the room with one helper.	18	One room that may be kept just for the 3-year-old group. If church sponsors weekday nursery school, this room and kindergarten room may be used. Rooms should be near each other.
Kindergarten, ages 4 and 5	12	Separate room. Do not encourage attendance of 3-year-olds at expense of 4- and 5-year olds.	20	One room that may be used both during church school hour and church hour. Limit use by others.
Primary, grades 1 and 2	12	One room where age group can meet, but if necessary, along with the entire church school session. May meet separately in a large, divided space.	16-20	Separate room for each 16-20 pupils. Beyond those numbers, two sessions or additional space needed. Grades one and two may meet together or separately.
Lower junior: Grades 3 and 4	10	Same as for primary.	16-25	Separate room, 16-25 in group. Beyond 25, additional space or two sessions needed.
Grades 5 and 6	8	One room or part of room in which juniors may be alone for at least 45 minutes a Sunday. Note: In all cases boys and girls should be grouped together.	16-25	Same as above for lower juniors.
Seventh grade				
Grades 7 and 8	6	If necessary, church school class may meet in church pew or in nearby home. For other types of activity, see below.	10-20	One room. (See notes below.)
Grades 9 and 10	6	Same as for grades 7 and 8.	8-15	One room.
Grades 11 and 12	10	Meet in church pews for church school classes. Junior highs and seniors may meet together for activities other than study and discussion. Ordinarily the church sanctuary, a home nearby, or the fellowship room is available for such use.	8-15	Same as above Program activities room may be coordinated for use by all junior and senior high groups. (See notes below.)
Older youth		If older youth are working, they may wish to form a group of their own or they may join with college students. If they are attending college away from home, let the college pastor know. If they are attending college at home, provide for a college-age fellowship. Facilities needed are both those listed in this section and those on chart for adults. In all cases boys and girls should be grouped together.		

Medium church school, 200-299 pupils		Large church school, 300-599 pupils		Very large church school 600 or more pupils
Enrollment	Housing facilities	Enrollment	Housing facilities	
6-10	Provide separate room with cribs and playpens for those under 18 months.	10	Separate crib and playpen room.	Similar to large church school, but these usually operate in two or three sessions and so have more adequate space for each age group.
6-10	Separate room needed for toddlers—or one room for above, with separate spaces for infants and toddlers.	12	Separate room for toddlers.	
30-36	Two rooms or two sessions. No more than 18 children in any one nursery class group. 15 a better figure.	30-36	Two rooms to be used by 3-year-olds only, or one room used for two or three sessions. No more than 15-18 in any one group.	
40	Two rooms, one for 4-year-olds, one for 5-year-olds. 20 limit in any one group. Or, two 4-5-year-old groups, 20 in each.	50-80	Four rooms—two for 4-year-olds and two for 5-year-olds or two rooms (one for each age) if there are two or three sessions. 20 limit.	
32-60	Two or three rooms, one for each 16-20 pupils. Grades may meet together or separately. May come together occasionally for common interests. These rooms may be used during the week by parents or other groups. Should be multipurpose.	64-80	Four rooms—or two if there is a second session. 16-20 pupils in one group. Grades 1 and 2 may meet together or separately.	
16-75	Same as for primary. May have up to 25 in one group.	64-100	Same as for primary. May have up to 25 in one group.	
16-25	Grades 5 and 6 may meet together or separately, boys and girls together. 16-25 the limit for each group.	32-75	Two or three rooms depending upon enrollment. See medium church school for further details.	

through youth

20-30	One room large enough for entire group. Smaller spaces for conversation and discussion. Class groups, 8-10. Flexible arrangement possible.	30-60	Flexible arrangement. One room needed where entire group may gather for sings, recreation, dramatics. Small rooms for conversation and discussion groups of 8-10 each.	Enrollment, 60—similar to large school. Multiple sessions provide more adequate space for each group.
15-25	Same as above for middle high, and senior high.	25-50	Same as above for middle high and senior high.	

The important arrangements for all three youth groups are:

1. A large space for the entire group for varied activities, such as recreation, sings, dramatics.
2. Small, intimate class groupings of 8-10 members each, in which there may be vigorous discussion, research, and study. This means use of the large space for two or three such groups (possibly), with use of other smaller rooms when enrollment necessitates. It is better not to have many small groups meeting in a single space. Intimacy and privacy of class groupings are essential at this age.
3. Formal worship provided by attendance at regular church service.

For any church to consider: When possible, the room used in the church school should be used for the Sunday evening or through-the-week program. Therefore, it should be suited to a variety of activities and provided with ample storage space for supplies and equipment.

Classrooms should be attractive, efficiently designed, and large enough for ample movement.

Recreation, crafts, hobbies, art activities, and drama are part of the ongoing program, and facilities should be provided for them. A kitchenette is desirable.

For a weekday schedule of activities, rooms should be near a building entrance for easy access.

Religious

CHURCH SCHOOLS

TABLE 2 Summary—School Equipment

Age group	Maximum children per room*	Floor space per child	Toilets, sinks, drinking fountains	Wraps	Cabinets
Nursery I, babies and toddlers birth to age 2	8-10 (Cribs at 3 ft intervals)	35 sq ft—good; 30 sq ft—fair; under 25 sq ft—poor. Separate room for babies and toddlers.	Toilets and wash basins within pre-school room area preferred. Otherwise, observe strictest sanitation facilities for storing and warming food.	Rod hangers in the room (preferably in storage cabinet with shelf above and below), 30 in. above floor. Full length for teachers. Hooks are hazardous. Not recommended.	Movable, ample for supplies.
Nursery II, age 2	8—good 10—fair 12—poor	35 sq ft—good; 30 sq ft—fair; under 25 sq ft—poor. (Warm clean floors for children to sit on. All preschoolers.)	Adjoining room with junior fixtures or wooden step if adult fixtures used. Toilets 10 in., basins 24 in. above floor.	Rod hangers in the room (preferably in storage cabinet with shelf above and below), 30 in. above floor. Full length for teachers. Hooks are hazardous. Not recommended.	Movable, ample for supplies needed. Low open shelves for toys.
Nursery III, age 3	Up to 15—good 15-18—fair Over 18—poor	35 sq ft—good; 30 sq ft—fair; under 25 sq ft—poor.	Adjoining room with junior fixtures or wooden step if adult fixtures used. Toilets 10 in., basins 24 in. above floor.	Rod hangers in the room (preferably in storage cabinet with shelf above and below), 36 in. above floor. Full length for teachers. Hooks are hazardous. Not recommended.	Movable, ample for supplies needed. Low open shelves for toys. Space for filing pictures and materials used in room. Open shelves for toys.
Kindergarten I, II, ages 4 and 5	Up to 20—good 20-25—fair Over 25—poor	35 sq ft—good; 30 sq ft—fair; under 25 sq ft—poor.		Rod hangers in the room (preferably in storage cabinet with shelf above and below), 42 in. above floor. Full length for teachers. Hooks are hazardous. Not recommended.	Movable, ample for supplies needed. Low open shelves for toys. Space for filing pictures and for materials used in room. Open shelves for toys.

* Rooms on first floor and above grade level.

TABLE 3 Rooms Needed in Relation to Program and to Size of Church School—Preschool Children

Age group	Church school, 1-99 pupils	Church school, 100-299 pupils	Church school, 300-499 pupils	Church school, 500-899 pupils	Church school, 900 or more pupils
Nursery I, infants and toddlers, under 18 months	Omit—unless suitable separate space is available.	Omit—unless suitable separate space is available.	Possible here to provide one room for toddlers. If there is a need, consider separate room with cribs and playpens, etc., for those under 18 months.	Separate crib and playpen room.	Similar to larger church schools.
Nursery II, ages 1½ and 2				Separate room for toddlers.	
Nursery III, age 3	May be necessary to house several 3-year-olds in same room as kindergarten. Try to separate parts of the room, using one helper.	Enrollment 8-18. One room that may be kept for just the 3-year-old group. If the church sponsors a weekday nursery school, this room and kindergarten room may be used. Have rooms near each other.	Enrollment 20-30. Two rooms. These may be used during the week by parent groups, etc., particularly if a folding partition separates them.	Enrollment 32-54. Three rooms to be used by 3-year-olds only, or one room used for each of two or three sessions.	These usually operate in two sessions.
Kindergarten I, II, ages 4 and 5	Enrollment up to 12. Separate room. Do not encourage attendance of 3-year-olds at expense of the 4- and 5-year-olds.	Enrollment 16-25. One room to be used both during the church school hour and church hour; limited use by others.	Enrollment 40-50. Two rooms, one for 4-year-olds and one for 5-year-olds. It is helpful to have rooms adjoining for possible use by adults.	Enrollment 64-100. Four rooms, two for 4-year-olds and two for 5-year-olds; or two rooms (one for each age) used for two or three sessions.	Three sessions would provide more adequate space for each age group.

Display space	Furniture	Other materials
Grooved picture rail 14 in. above floor. Tack board extending from 14 to 38 in. above the floor.	Cribs—preferably bassinets on metal frames with rubber tires. Playpens, bed linen, plastic mats for playpens.	
Grooved picture rail 17 in. above the floor. Tack board extending 17 to 43 in. above the floor.	Chairs 6 in. from floor. Not needed for every child. Tables—height 16 in. — small. Tops 18 by 24 in. A book table—not essential if space limited.	Large blocks (2 x 4 x 8 in. and 2 x 4 x 12 in.); floor toys (peg wagon, wooden, train, cars); books; pictures; a Bible; cuddly toys (stuffed animals, rag dolls); housekeeping toys (doll, doll bed, tea table and dishes); ball; picture rail; offering container; wastebasket; growing plants or other nature materials; a songbook, or collection of songs, recommended in the literature for use by the leaders. Add later (where space permits) walking board; more housekeeping equipment (pans, telephone, small rocking chair); push and pull toys; small wagon, resting mats; washable rug or rugs for floor.
Grooved picture rail 20 in. above the floor. Tack board extending from 20 to 48 in. above floor.	Chairs 8 in. from floor. A few 6 in. Tables, height, 18 in. Tops, 24 by 36 in. or 28 by 42 in. Teacher's table, 18 by 24 in. Piano—not essential but desirable.	Large blocks (2 x 4 x 8 in. and 2 x 4 x 12 in.); floor toys (cars, trucks, train, boat); ball, books; a Bible; pictures; housekeeping toys; a songbook, or collection of songs, recommended in the literature for use by the leaders; offering container; wastebasket; growing plants or other nature materials. Add later (where space permits) easels for painting; paint; set of steps; large hollow blocks; more housekeeping toys (broom, ironing board, iron, clothesline, doll carriage—large enough to come to waist of child); large puzzles, sets of wooden animals and people for block play; low bench or stools near place for wraps.
Grooved picture rail 24 in. above floor. Tack board extending from 24 to 54 in. above floor.	Chairs 10 in. from floor. Tables, height 20 in. Tops 24 by 42 in. or 28 by 48 in. Piano desirable.	Large blocks (2 x 4 x 8 in. and 2 x 4 x 12 in.); floor toys for dramatic play; books; a Bible; pictures; housekeeping toys; paper scissors; large crayons; a songbook or collection of songs, recommended in the literature for use by the teachers; offering container; wastebasket; growing plants or other nature materials; display or tack strip space. Add later (where space permits) easels for painting; paint; large hollow blocks; large puzzles; sets of wooden animals and people for block play; small aprons, nurses' caps, pocketbooks, ties, for dramatic play in housekeeping center.

TABLE 4 Rooms Needed by Elementary Children as Related to School Size

	Church school, 1-99 pupils	Church school, 100-299 pupils	Church school, 300-499 pupils	Church school, 500-899 pupils	Church school, 900 or more pupils
Primary, grades 1, 2, and 3	Enrollment up to 18. One room where age group can meet, but if necessary along with the entire church school session. May be part of large space divided.	Enrollment 24-54. One room; or one large room and one medium size room for approximately 25. Two grades can use large room for all purposes. One grade can use smaller room for all purposes or unite with the other two grades.	Enrollment 60-90. Three rooms—one for each school grade to be treated as three separate groups; or may come together occasionally for worship or other purposes.	Enrollment 96-162. Six rooms—or three if there is a second session. Handle as separate groups.	Have more adequate space for each age group.
Junior, grades 4, 5, and 6	Enrollment up to 15. One room or part of room in which juniors may be alone for at least 45 minutes a Sunday. May have to worship some of the time with older groups in the church school.	Enrollment 20-45. Same as requirements for primary children.	Enrollment 50-75. Three rooms, one for each grade; or one large room and one medium size for approximately 30.	Enrollment 80-135. Same as for primary.	

TABLE 5 Summary of Space and Equipment for Elementary School Children

Age group	Maximum children per room*	Floor space per child	Toilets, basins, drinking facilities	Wraps
Primary, grades 1, 2, and 3; ages 6, 7, and 8	Up to 25—good 25-30—fair 30-35—poor (See comment below for assembly)	30 sq ft—good 25 sq ft—fair 20 sq ft—poor	Separate toilets for boys, girls. Readily accessible on same floor. Washbasins 28 in. from floor. Toilets 14 in. from floor. Sink with running water and double drain board in room preferred.	Some prefer in room. Use rod hangers 42 to 48 in. above floor, shelf above.
Juniors, grades 4, 5, and 6; ages 9, 10 and 11	Up to 25—good 25-30—fair 30-35—poor Up to 45 pupils, 3 rooms; 1 larger for assembly at times.	20-30 sq ft—good 25 sq ft—fair 20 sq ft—poor	As above except basins 30 in; toilets 16 in. from floor.	Some prefer in room, otherwise in recessed corridor storage space. Use rod hangers 48-54 in. above floor, shelf above.

* Preferably on first floor, above grade level.

TABLE 6 Rooms Needed in Relation to Program and to Size of Church School—Youth Division

	Church school, 1-99 pupils	Church school, 100-299 pupils	Church school, 300-499 pupils	Church school, 500-899 pupils	Church school, 900 or more pupils
Junior high	Enrollment up to 12. Church school class may meet in church pew or in nearby home. For other types of activity, see below.	Enrollment 12-35. Church school classes may be held in sanctuary if necessary but a meeting space is needed for other program activities.	Enrollment 35-60. Department Assembly Room, plus two classrooms large enough for classes of 15-20. Assembly room may be used for through-the-week activities.	Enrollment 60-100. Department Assembly Room with classrooms for groups of 15-20. Assembly room should be available for activities of junior highs throughout the week.	Enrollment 100 or more. Three departments should be provided, one for each grade. Provide each section with an Assembly Room and classrooms.
Senior high	Enrollment up to 10. Meet in church pews for Church school classes. Junior highs and seniors may meet together for activities other than study and discussion. Ordinarily the church sanctuary, a home nearby, or the fellowship room is available for such use.	Enrollment 10-30. Same as above. Separate room should be available for program activities.	Enrollment 24-40. Assembly Room with two classrooms. A third class may meet in the assembly room itself. Such a room also becomes a headquarters for the Youth Fellowship.	Enrollment 50-90. Department Assembly Room with classrooms for groups of about 20.	Enrollment 90. Department Assembly and Room with classrooms over for groups of not more than 25.
Older youth	<p>If older youth are working, they may wish to have a group of their own, or they may join with college students.</p> <p>If they are attending college away from home, let the college pastor know.</p> <p>If they are attending college at home, provide for a college-age fellowship. Facilities needed are both those listed in this section and those under "Adult."</p>				
	<p>For any church to consider:</p> <p>Where possible the same room should be used for assembly and worship in the church school and also for Sunday evening or through-the-week program. Therefore, it should be suited to a variety of activities and provided with ample storage space for supplies and equipment. Classrooms should be attractive, efficiently designed, and large enough to allow for ample movement.</p> <p>Recreation, crafts, hobbies, and drama are part of the ongoing program and facilities should be provided for them. A kitchenette is desirable.</p> <p>For a weekday schedule of activities, room should be easy of access, near building entrance.</p>				

Cabinets	Display space	Furniture	Other materials
Ample space carefully planned for pupils' and teachers' supplies, handiwork, picture storage. Open shelves for books.	Grooved picture rail 30 in. above the floor. Tack board 30 to 62 in. above the floor. Portable blackboards or turnover charts made for handling and tack boards on one or two sides of room.	Chairs 14 in. from floor, some 12 in. Table tops 30 by 48 or 54 in., 24 in. high. Small tables for beauty or worship centers. Piano. Record player.	Recommended literature, one or more Bibles, paper, pencils, crayons, paste, scissors. Songbook for pianist and teacher's use (one recommended in the literature). Pictures, books chosen according to unit being studied; simple reference books. Song charts. Growing plants or other nature materials, wastebasket, picture rail, movable blackboard or large sheets of newsprint on an easel may be desired.
Same as above but provide storage for maps, large objects.	Grooved picture rail 36 in. above the floor. Tack board 36 to 72 in. above floor.	Chairs 16 in. from floor. Table tops 30 by 48 or 54 in., 26 in. high. Piano. Small tables for beauty and worship center. Record player.	Recommended literature, a Bible for the department, a Bible for each child. Songbooks for children's use (one recommended in the literature), pictures. Books chosen according to unit being studied, paper, pencils, crayons, paste, scissors; offering container. Wastebasket, growing plants or other nature materials, picture rail, movable blackboard or large sheets of newsprint on an easel may be useful. Add later Bible dictionary; Bible atlas, maps, a globe, reference books, copies of different translations of the Bible, a dictionary.

TABLE 7 Summary of Space and Equipment for Youth*

Age group	Maximum pupils per room	Floor space per pupil	Furniture and equipment
Junior high I, II, III, and grades 7, 8, and 9; ages 12, 13, and 14	20 pupils — good 10–15 pupils — preferred	15–18 sq ft — good 12–15 sq ft — fair 10–12 sq ft — poor	Lightweight tables without drawers. Space to store extra tables and chairs. Comfortable, sturdy chairs, blackboard or turn-over chart frames with large sheets of paper. Display board, wall maps, youth library, pianos, record player and record storage, recreational equipment and place to store it. Bibles, textbooks, etc.
Senior high and older youth; grades 10, 11, and 12; ages 15, 16, and 17	25 pupils maximum	Same as above	Equipped for audiovisuals. Nearby accessible cloak storage space, toilet facilities. Storage cabinets for pictures, hymnals, materials and supplies. Colorful, attractive furnishings in keeping with decor of building.
Older youth, 18–23 years			

* Provision should be made for recreation, worship, handicraft and hobbies, dramatics, youth choirs, and refreshments.

CHURCH SCHOOLS

TABLE 8 Rooms Needed in Relation to Program and to Size of Church School—Adult Division*

	Church school, 1-99 pupils	Church school, 100-299 pupils	Church school, 300-499 pupils	Church school, 500-899 pupils	Church school, 900 or more pupils
Young adult	Enrollment up to 10. Church school class may meet in sanctuary or in nearby home. Social, recreation, and service activities of class, and of young adult fellowship, may use church dining room or homes of members.	Enrollment up to 30. One classroom advisable especially for parents' class, or a mixed group. Class may use sanctuary. For other class and young adult fellowship activities use may be made of church fellowship hall, or similar room and homes of members.	Enrollment up to 50. Two classrooms advisable; one for parents' group, one for a mixed group. Sanctuary pews may be used. Young adult fellowship Sunday night and week night activities in fellowship hall or other rooms, or in homes. Provision needed for dramatics, recreation, and audiovisuals.	Enrollment up to 50. Same needs in general as medium church school, except provision for more class groupings according to interest needs. A church hobby room would enlist many young adults. Provision needed also for dramatics, recreation, and audiovisuals.	Enrollment 100 or more. Same needs in general as large church school. More activities on Sunday night and week nights will need church space because homes cannot usually accommodate larger attendance.
Middle adult	Enrollment up to 10. Church school class may meet in sanctuary or nearby home.	Enrollment up to 30. One or two class meeting places in sanctuary or available rooms in other parts of the church.	Enrollment up to 50. Same general space and equipment needs as medium church school, with allowance for larger attendance and provision for informal interest groups.	Enrollment up to 90. Same general space and equipment needs as medium church school, with allowance for more classes, especially short-term interest groups.	Enrollment 100 or more. Smaller classes of 20 to 30 preferable to one or two large classes.
Middle adults will also be active in men's fellowships, women's associations, and other organized groups and will need space and equipment for such activities. However, these meeting places will probably be used by other age groups at other times, thus making it unnecessary to build and equip these rooms for adults only. Storage space must thus be provided for equipment that will serve the different age groups.					
Older adult	Enrollment up to 7. No special facilities needed. Older adults will probably participate in middle adult study and activities.	Enrollment up to 21. May participate with middle adults. If separate class is needed, a section of the pews in the sanctuary will probably be available	Enrollment up to 35	Enrollment 85 or more	Enrollment up to 85

* The enrollment figures used in this chart are based on a sampling of a variety of church schools. It was found that there were approximately 27 adults to every 100 pupils enrolled in the church school. The figure 27 was broken down into 10 young adults, 10 middle adults, and 7 older adults. However, church school situations are so varied in proportionate age groupings that many exceptions must be made.

Space should also be considered for meeting of entire adult department of the church school. An office for administration of the adult department, and for records, is desirable. A fellowship hall with stage, kitchenette, provision for audiovisuals, hobbies, recreation, and service activities will provide for a multiplicity of uses for almost every kind of adult need.

TABLE 9 Summary of Space and Equipment for Adults*

Age group	Maximum persons per room	Floor space per person	Furniture and equipment
Young adults, ages 24-35	20-25 preferred 50 persons maximum	Lecture type, 8-10 sq ft per person	Facilities for study groups and discussions, tables for discussion groups and study, comfortable chairs, blackboards or turnover charts, lecterns, pictures, Bibles, books, pianos, cabinets for supplies, provision for dramatics and audiovisuals.
Adults, ages 36-64		10-12 sq ft for activity-type teaching	Facilities for teas, light refreshments, suppers, hobby and recreation, and informal fellowship weekday clubs, recreation, etc.
Older adults, age 65 up			Small meditation room apart from the nave or chapel.

* For adults and older adults, rooms should be on first floor, if possible.

TABLE 10 Rooms Needed in Relation to Program and to Size of Church School Administrative Functions

Persons and functions	Church school, 1-99 pupils	Church school, 100-299 pupils	Church school, 300-499 pupils	Church school, 500-899 pupils	Church school 900 or more pupils
Pastor	Study and work room. Built-in table and shelves with curtain or doors to conceal mimeograph equipment when not in use.	Study and separate work room. Closet for supplies.	Study and office for secretary with equipment for records. Work room with cabinets for supplies.	Study with office for secretary. Office for church secretary. Offices for other staff members and their secretaries. Work room and supply closets.	Same as for 500-899 church school with addition of conference or board room adequate for largest group, should have table, exhibit space, blackboard, A-V equipment.
Director of Christian Education	None.	None.	Office large enough for desk, table, bookcases, and chairs. Space for counseling and small committee work.	Office large enough for desk, table, bookcases, chairs, with space for counseling and committee work. A separate office for secretary.	Same as for 500-899 church school plus offices for age group assistants and their secretaries.
Church School Supt., Secretary, and Treasurer	Desk space with shelves or chest of drawers for literature, supplies, and records.	Room with desks and cabinets for records, literature and supplies.	Room with desks, cabinets for records, literature, and supplies.	Room with desks, work table, filing cabinet for records. Storeroom for literature and supplies.	Same as for 500-899 church school but with increased space.
Choir Director	Desk or table space. Cabinet for filing church music. Closet or cabinet for choir robes.	Room with desk or table. Cabinets for music and choir robes. Shelves for hymnals used by choir.	Office with desk, cabinet, and piano. Room with table, and cabinets for music, choir robes, hymnals.	Office and studio with piano. Room for robing of choir with cabinets for music, robes, and hymns.	Same as for 500-899 church school but with more ample robe closets and robing space.
Library	Built-in bookcases with locks, or space for movable units. Filing cabinets for records.	Room with bookcases (built-in or movable), table, chairs, filing cabinet for records. Cabinet for picture files.	Room with bookcases, table, chairs, cabinets for records, filing pictures and maps. Exhibit cabinets.	Large room with tables, chairs, with space for reading and study. Picture and files. Cabinet for records. World friendship museum.	Same as for 500-899 church school but with increased space and equipment.

Steps to be taken in planning and constructing a city hall are (1) determining need, (2) determining space requirements, (3) selecting an architect, (4) acquiring a site, (5) approving layout, design, and architectural features, and (6) developing a financial plan. These steps are not a one-two-three process; frequently they must be done simultaneously. It is important to have an idea of what is wanted before selecting an architect, but the architect can be helpful in delineating wants. It is important to remember that the city hall must last 60 years or more. The following "dos and don'ts" provide a guide to officials engaged in planning a new city hall.

Do:

1. Locate the city hall where it will be most convenient and if possible where land values are reasonable.
2. Be prepared to provide the architect with information on departments to be housed, the number of employees, types of furnishings and equipment, and special requirements such as vault and storage space.
3. Provide ample off-street parking space for both employees and the public.
4. Put most or all city department headquarters in the city hall.
5. Provide for structural expansion and flexibility in office layout.
6. Plan the city hall from the inside out with emphasis on work flow, convenience to the public, and convenience for employees.
7. Provide for the comfort and efficiency of employees with controlled ventilation and adequate lighting.
8. Provide for employee lounges and rest rooms.
9. Use materials, construction, and furnishings which make the city hall easy to maintain.
10. Provide open, unobstructed counters for transactions with the public.

Don't:

1. Don't locate in an area of declining property values except when part of a comprehensive urban renewal program.
2. Don't try to remodel an old post office, school building, convention hall, or other building designed for some other special use.
3. Don't forget that the city hall is an office building, not a monument or an ornament.
4. Don't underestimate space needs; the average commercial office building lasts 67 years.
5. Don't tie up valuable space with indoor pistol ranges, drive-through garages, private exits, wide corridors, and other gadgets.
6. Don't cut up the city hall into cubbyholes for minor officials.

7. Don't build the city hall over two stories in height if at all possible.

8. Don't let the public come in contact with police or criminal activities.

9. Don't provide in the main lobby any facilities, such as a cigar and soft drink stand, which encourage loitering.

DETERMINING NEED

The need for a new city hall may seem obvious to those who spend their working hours at the city hall. Ceilings are high; heating costs are twice what they should be; space originally meant for storage has been converted to offices; electrical wiring violates code provisions; and the present facility is just old anyway. All of this—and more besides—may be true, but what is not known is how extensive the need is. This must be determined by careful study. In determining the need for a city hall alternate courses of action should be studied.

Factors Influencing Need Determining the extent of need involves two areas: (1) condition of building, and (2) space needs.

The condition of the building is the easiest to evaluate. Things to be considered are type of construction, structural condition, electrical wiring, heating and ventilating, and facilities such as rest rooms. Nothing may be seriously wrong and a new facility still needed, but it is important to know these points. Careful and professional review may bring factors to light heretofore not considered.

At an early stage it is important to have some idea of space needs. This can be determined in general terms by having each department submit their space needs for review and study. If departments are already crowded, additional space needed now is not hard to estimate. The real problem in determining space needs is what will be needed in the future. The building may be adequate now, but will it be in 5, 10, 20 years? Few cities decide to build a new city hall and do so almost immediately. Experience seems to indicate that a new city hall is the outgrowth of a number of years of careful planning and, once built, lasts a long time.

In estimating future needs not only must traditional services such as police and building inspection be considered but also what future services the city may be required to provide. One of the "dos" is to provide for structural expansion. However, provision for such expansion must be in reason, and should be based on projections of future needs. Knowledge of the community and its people is essential to space planning. City officials should know the population projections for the next 20 or 25 years, the economic level of the community, and present and probable social and economic characteristics.

SELECTING THE LOCATION OF THE CITY HALL

Civic Centers In selecting the location for a city hall, the first consideration is whether it should be placed on a site by itself or whether it should

be combined with a group of related buildings in a civic center. The civic center has had great appeal to the city planner because it offers certain advantages and at the same time provides for latitude in design. The buildings that are included in civic centers range from a grouping of strictly administrative offices and service buildings to a complex of office buildings, auditoriums, libraries, and so on.

The great advantage of a civic center is that the grouping of public buildings may prove to be convenient to the public in transacting business that requires visits to more than one public agency. It also may result in one or more governmental units being able to use the facilities of the other. Finally, it often is convenient to have certain facilities grouped together in order to expedite interagency and governmental relations.

Obviously if a city hall is to be part of a civic center, it must be planned in relation to the other facilities. For instance, the San Jose, California, city hall is part of a civic center consisting of a health building, communications building, police garage, county office building, sheriff's department and jail, criminal-legal building, and a juvenile center. Some of the facilities, such as the administrative offices in the health building, did not have to be repeated in the city hall.

Site selection for a civic center must consider the factors listed below for locating a city hall. In addition, several other points are important. The site for a civic center must permit flexibility in building arrangement. Since more land is necessary, street patterns may have to be altered, and additional land will be needed for parking. Once the site has been selected, means must be found to preserve it for gradual development of all the units. Also, the site must be located so as not to interfere with the normal development of the business district.

On the surface the civic center idea has great appeal. There are those who feel that center concept has limitations. An article by Richard A. Miller entitled "Are Civic Centers Obsolete?" *Architectural Forum*, January, 1959, highlights these objections. Miller points out that cities range in size "from mammoth concentrations" to small cities. "As a rule, the concentration of community buildings can be increased in inverse ratio to the size of the city." One of the strong points made in the article relates to the discussion above on decentralization of city offices:

Government buildings—the city hall, fire station, and police stations—which were long the nucleus of most civic centers, tend themselves to be dispersed today. The reason is obvious. Fire and police buildings, for example, are best located at a central point in the street network, and with the building of expressways, this point rarely intersects with the best location for the mayor's office or the council chamber. Service agencies (such as the water and park departments) increasingly favor headquarters locations adjacent to their operating facilities. In Philadelphia, where two new government office-type buildings will be erected, the city also plans to remodel and expand the old city hall in Penn Center to

Governmental and Public

CITY AND TOWN HALLS

house the mayor and the council—thus retaining a symbolic center of government in the heart of the city.

City-County Building The county-seat city should investigate the possibility of constructing one building to serve the needs of both the city and the county. At least 40 cities and counties occupy the same building.

The city-county building has two major advantages. First, local governmental facilities are together, which is frequently a convenience to the public and to city and county agencies that have contact with each other. The second advantage is cost savings. Depending on conditions, a joint building can be constructed for less money than two separate facilities when all costs are considered: land, engineering and architectural fees, financing charges, and so on. Joint occupancy can result in operating savings.

The majority of cities that occupy office space with the county feel that the arrangement is very satisfactory. The most often stated disadvantage is lack of room for expansion. A joint city-county building must be carefully planned so that both governmental units have areas to expand in. A city and a county have different as well as similar needs. When the differences are too great, a city-county building can cause problems. The other drawback is that expenses and responsibilities for operating the building are not always distributed equitably. It is thus extremely important that an agreement for building operation and maintenance be worked out in advance of construction.

Location The selection of a site for a city hall will be influenced by a number of circumstances. Some of these conditions are limiting in nature, such as the availability of land. There are, however, certain guiding principles that should be considered. When Tacoma and Pierce County decided to build a city-county building the planned commissions of each governmental unit jointly developed a set of location factors. The six applicable principles for a city hall location are as follows:

1. "Government must serve and be accessible to the people. . . . Efficiency of service is related to how convenient governmental facilities are for the majority of those citizens using the facility.

2. "Since public services must serve every citizen as well as, and as conveniently as possible, those activities must be located near the center of transportation and the center of business activity. In the large city public transportation comes to a head in the central business district. Major arterial streets are planned to bring people in and out of the city center. In most cases the city hall should be located near public transportation, if any, and certainly near major arterial streets.

The city hall should be near the center of business activity because this is where the principal users of the facility are most frequently located. As an example, attorneys frequently must use records that are housed in city hall. A city should determine what groups most often come to city hall and place the facility as close to those groups as possible.

3. "Government offices must have integration with, not isolation from, other offices in order to serve the public efficiently and effectively." City government agencies use the services of professional men and other businesses. Locating the city hall near the center of business activity helps expedite the work of the agencies located in city hall.

4. "Maximum use of transit systems will result in the least public parking areas and

cause the least congestion on city streets." Obviously this applies only to the city having some form of public transit. People travel either by walking or by using cars, taxis, or public transit. If the city hall is readily accessible to automobiles only, parking requirements would increase in direct ratio to the increased use of the car. For the city that does not have transit systems, location in the center area of the city may help to reduce parking requirements. People come to the city center to do a variety of things; frequently they park and walk between different places of business.

5. "The central business district is the real civic center of the 20th century." A lot has been said about the deteriorating central business district. The impression has been given that the central city is drying up; that everything is moving out. Thus why not the city hall. In the first place there is good reason to believe that the moving out has largely been the retail store and to a lesser extent the office building. Secondly, in the large city, the concentration of people makes it possible for certain types of business, including retail, to operate more efficiently; in the small city the general business area is staying intact for the same reason. A city cannot afford to allow the central business district to dry up because of the investment it represents. The proper placement of the city hall in the central business district can contribute to the life of this area.

6. "More than the initial land cost must be included under the economic considerations of the site. . . ." The site should allow for expansion. Site development cost must be considered. These expenditures include demolition of existing structures, if any, grading utilities, and flood protection.

LAYOUT, DESIGN, AND CONSTRUCTION FEATURES

General Building Layout Building arrangement is the next step in planning a city hall. It is helpful as a starting point to use the following checklist of departments, offices, special-purpose rooms, and service areas in analyzing interior building requirements:

1. Departments requiring constant contact with the general public and the collection or payment of money—for example, the finance department and tax collector

2. Departments requiring contact with special classes of the public—for example, city-owned utilities, building permits, personnel, city planning, and city clerk

3. Other departments including public works, recreation, police, fire, etc.

4. City council chamber and office space for use by the mayor and councilmen

5. Offices for the chief administrator

6. Courtrooms

7. Storage vaults and record rooms

8. Locker rooms, rest rooms, janitor closets, public telephones, and space for heating, ventilating, plumbing, and electrical equipment

9. "Circulating areas" for lobbies, corridors, elevators, and stairways

The relationship of one room or functional area to another is important. No room exists by itself, and many of the problems of living in a building arise from the neglect of this fact. Departments related in function should be located near one another and consecutive operations planned in production-line style. Excessive lobbies and hall space add to the cost of construction without adding usable space.

The height of the building will depend upon the amount of ground available and the amount of office space needed. Land generally is cheaper than additional height. Taller buildings

are more difficult to maintain and require more planning of the interior to get related functions on adjacent floors. Also any city building of more than two floors should have an elevator, especially if the public has any great use of the top floor.

Provision for a full basement housing general offices is not often made in new city office buildings. Most professional organizations advise against locating general offices in the basement. The basement can be used for storage and service activities such as duplicating, receiving and shipping rooms, heating and air-conditioning equipment, and central switchboard.

Departmental Layout Departmental layout will depend on the activities carried on by the department and the tools or special equipment used. For example, a finance department layout may require an open area for accounting clerks and collectors with one or two private offices, a machine room, and a vault. The public works department, on the other hand, may require private offices for the director, the engineer, and individual inspectors, a drafting room, a vault, a plan or map room, and conference rooms.

The first step in departmental layout is to survey the work done by the department. Work flow should be especially studied. A complete list should be made of all employees and equipment to occupy the space. The possibility of future expansion should be anticipated and provision made for additional personnel. Provision also should be made for peak rather than average work loads. Flow of work should, as nearly as practicable, be in a straight line. Normally, work should come to the employees rather than their going to the work. Minor activities can be grouped around areas of major activity.

Private Offices A major factor in the determination of space needs is the question of who should get private offices and under what circumstances. More space is required for private offices; space utilization is restricted through segregation of areas for private offices; and considerable expense is involved in rearranging and erecting partitions. Ventilation, lighting, and heating problems are complicated by a number of small offices; supervision and coordination of work, flow of work, and communications are made more difficult. An open, well-arranged office has a more orderly and businesslike appearance than a series of small offices.

Certain conditions justify private offices. First, transactions of a confidential nature require private facilities. General conference rooms, however, where confidential meetings may be held as occasion demands, may reduce the need for private offices. Second, privacy is often desirable not so much because of the confidential nature of the work, but because of the number of persons interviewed or because the work is of an independent nature which requires more quiet and privacy than the open office will allow. There is little agreement as to who should have private offices except for the chief administrative officer and department heads.

Chief Administrator's Office The location of the chief administrator's office is important to good public relations. It should be located so as to give the impression of being easily reached and open to any caller, but it should not be too prominent. The second floor ordinarily is a good location since some effort must be expended to visit it, and the casual or merely curious individual is less likely to intrude.

Governmental and Public

CITY AND TOWN HALLS

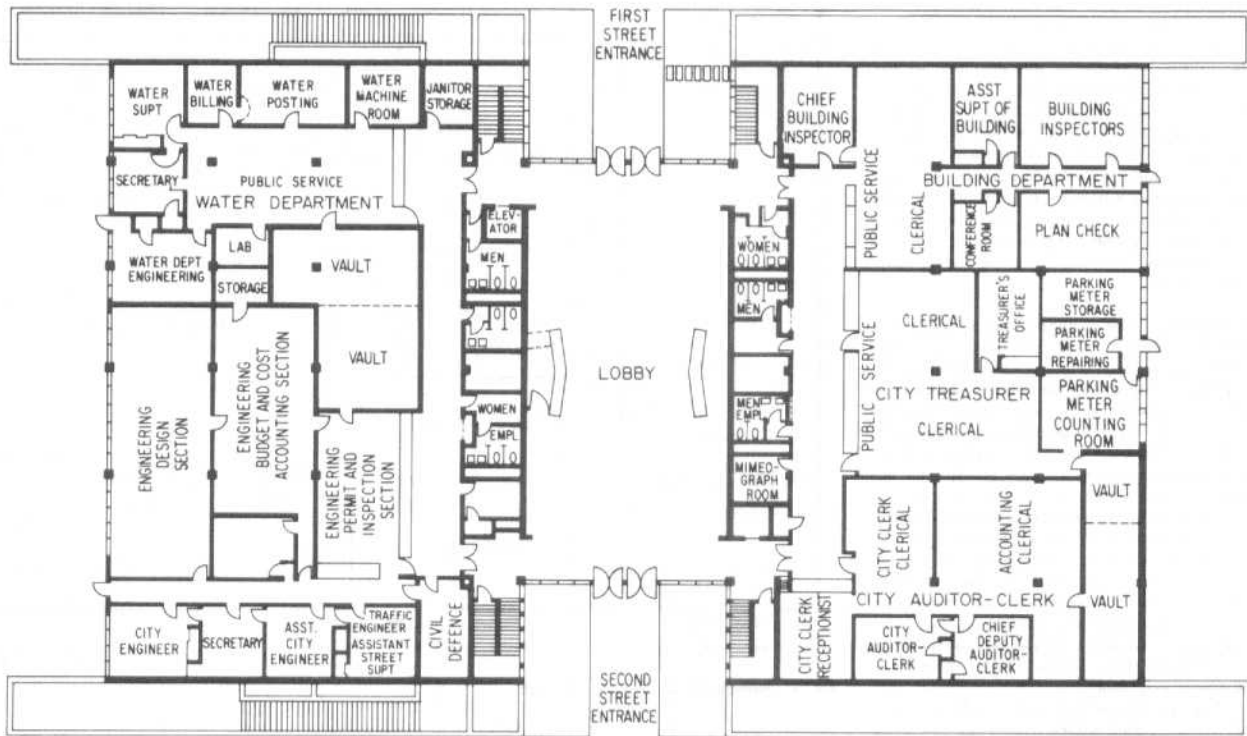

A first-floor location, however, can be just as good if callers are properly screened by a secretary or receptionist. It has the additional advantage of being close to the offices most frequented by the public. Of interest to council-manager cities is the fact that the mayor has an office in the majority of cases located very close to the city manager's office. See the

second-floor plan of the Alhambra, California, city hall (Fig. 1) for a typical executive layout.

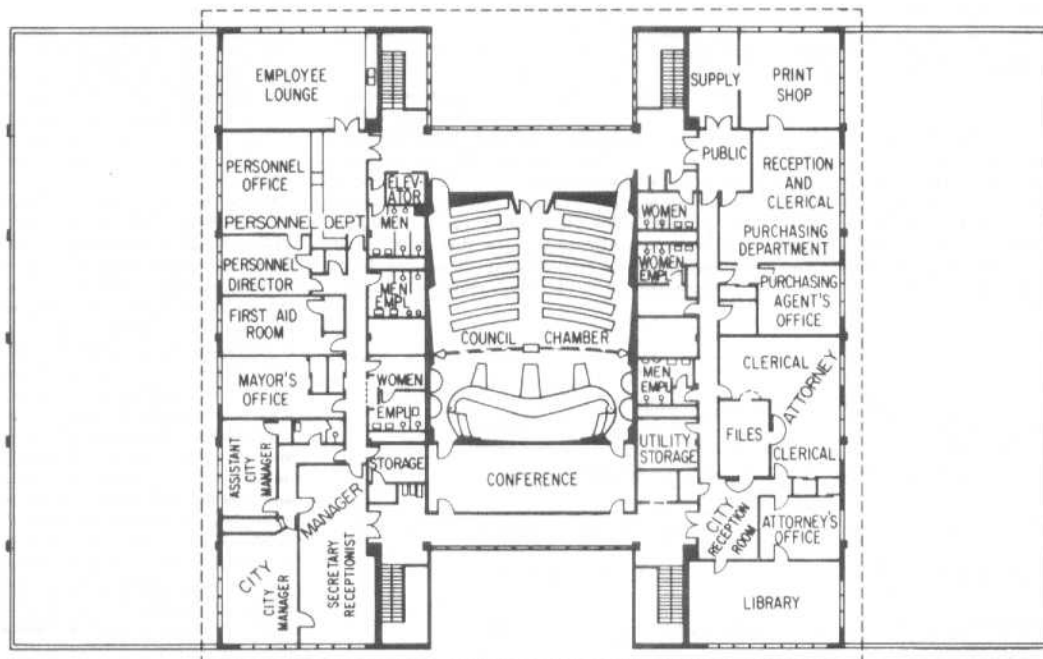

The administrator's office should be large enough for meetings of department heads unless a conference room adjoins his office. A conference table that will accommodate up to 12 people is desirable. Space should be provided adjacent to the administrator's office

for a secretary and one or more assistants, depending upon the size of the city. The secretary's office would also serve as a reception room for people who call on the administrator.

Council Members The council meeting room should be carefully planned if full use is to be made of it. Location of the council chamber is

FIRST FLOOR PLAN

SECOND FLOOR PLAN

Fig. 1 Alhambra, California, City Hall.

Governmental and Public

CITY AND TOWN HALLS

important because of the public nature of the business transacted there. Most of the cities with multistoried buildings have located the council room on the first or second floor.

The offices located near or around the council chamber are usually those of the city clerk, city attorney, and city manager. Small meeting rooms and an office for the mayor and councilmen may be located nearby.

In most cities surveyed, councilmen sit at separate desks or at a semicircular table, the open end of which faces the citizens. In only a few cities do the councilmen have their backs to the public. The mayor usually sits in the center flanked by the manager, clerk, and attorney. The council table often is put on a dais 18 in. or 2 ft above the main floor (see Fig. 2).

It is well to plan the council chamber so that it also can be used for other purposes. In many cities it is used as a general courtroom for public hearings held by city agencies, as a meeting room for the city planning or zoning commission, for general conferences, and as a public meeting room.

Finance Activities The collection activities of the finance department have more contact with the public than any other municipal activity with the possible exception of the police and building departments. A prominent location near the front entrance is therefore desirable. Avoidance of cubbyholes for separate functions and provision for a large work area enhance the appearance of the building and give the impression of a well-planned and efficient layout. Collection functions should be located near the public counter with billing, assessing, accounting, budgeting, and purchasing at a greater distance. These activities should be so grouped and arranged that the supervisor can observe the work of all his employees. A drive-in collection window should be provided where possible.

A separate, soundproofed machine room should be provided where machines are used in accounting or billing. Acoustical ceilings and walls, thermopane glass partitions, and carpeted floors will absorb much of the machine noise and make for more efficient working conditions in the general office. A vault for safekeeping of records should be provided unless one is provided near by in the city clerk's office.

Police Department The police department is singled out for discussion because of the special facilities it needs other than regular office space. As noted, the police department is frequently not included in the city hall. When it is, however, it should be basically separate from other city hall activities, and public and criminal activities should be separated.

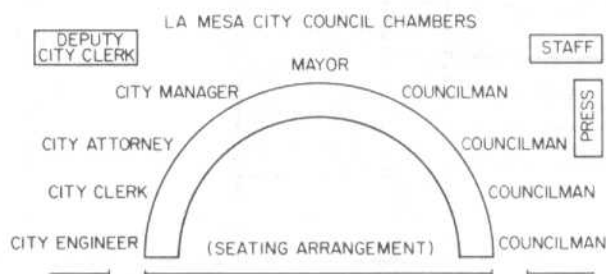

Fig. 2 City Council seating arrangement, La Mesa, California.

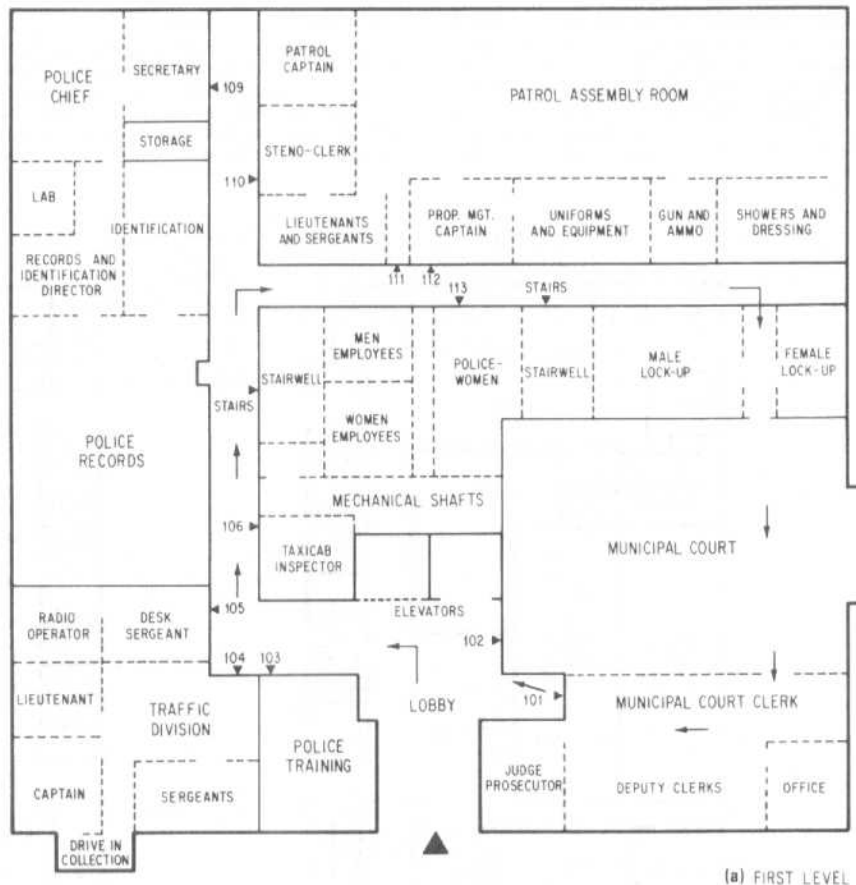

Fig. 3 Raleigh, North Carolina, City Hall.

The extent of facilities will depend largely on the size of the community and the size of the department. In planning police station facilities, several basic needs should be considered by all cities. Jail cells should be away from public areas. Prisoner retention for any period requires toilets, kitchen facilities, and separation of men and women prisoners. Because of the expense of cellblocks, the possibility of using county jail facilities should be investigated. Many communities contract with the county for prisoner care. This may be impractical for very large cities, but cities up to 100,000 certainly can effectively use this method of reducing police station cost. If county facilities are used, it is then necessary only to pro-

vide a retention room or rooms with toilet facilities. Such rooms do not need to be regular cells.

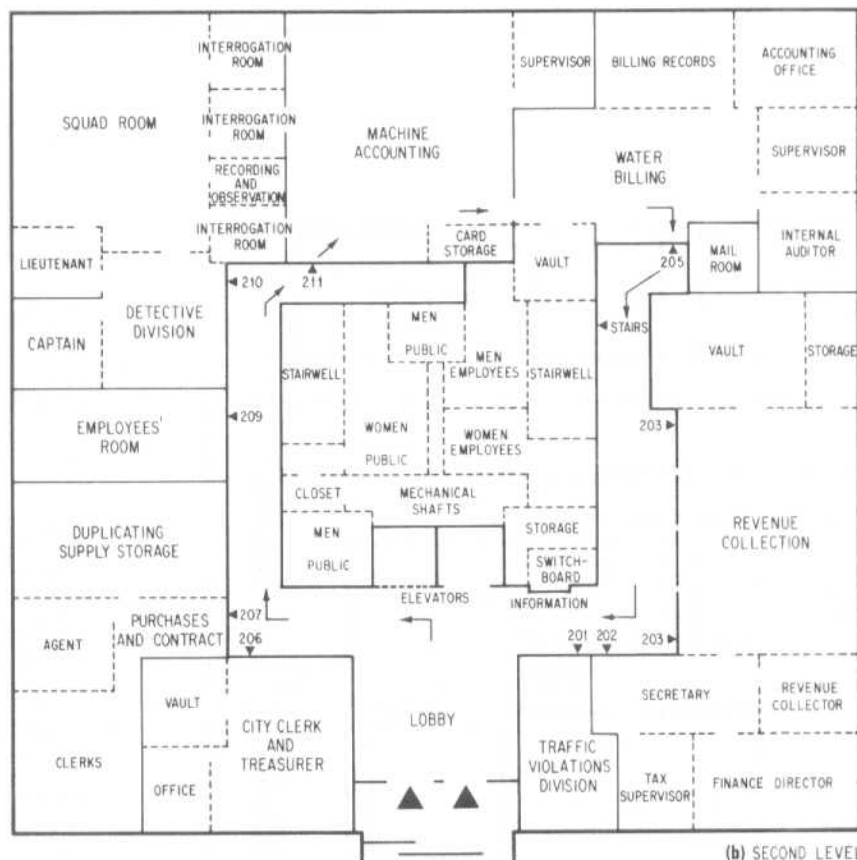

The communications center should be isolated from the general public and other work areas. However, in smaller communities where it is necessary for communications personnel to act as receptionists, this is not possible. In such a case the communications section might be located in a glass enclosure with a sliding panel.

Fingerprinting, photographic, identification, and booking areas should be located together, although not necessarily in the same room. Where possible, a separate prisoner entrance leading directly into the area for booking should be provided. The essential element is to provide a continuous process of booking, fingerprinting, photographing, and identifying of prisoners in the same area of the building. Where possible, it is desirable to have the area near the jail or retention area.

Provide plenty of space for storage. Firearms and other equipment should be stored in locked cabinets. Room for confiscated, lost, and abandoned articles is necessary if such items are to be kept properly.

When patrolmen change shifts on beats it is not necessary to have a large assembly room, but it is desirable to provide space for officers to fill out reports. In large departments, the detective force will need a separate room with lineup facilities.

In the very large departments separate rooms for interrogating prisoners are neces-

sary. In the medium-sized department, the detective squad room can be used for interrogation. A separate room for the use of prisoners and their attorneys or visitors is important when the station has facilities for housing prisoners. Finally the large city should have a courtroom near the jail or detention facilities of the police department.

The police department facilities of the Raleigh city hall are well planned (Figs. 3a-c). Separation is achieved by having the police department on ground level except for the detective bureau. The detective bureau is reached by a stairwell located so that the general public would not have use for it. Notice that the traffic violations division is on the second level right across from the city clerk and treasurer's office. This places money collecting in one area and very convenient to the public. The municipal court is off the lobby on the ground level and next to the male and female lockups.

Design of the City Hall The city hall is essentially an office building, not a monument or an ornament. The building should be so designed as to be economical in construction and maintenance. True long-range economy is achieved by a judicious balance between original cost and maintenance cost. A building with cheap materials and equipment for the sake of low first cost may be quite expensive in maintenance and replacement.

Even though the city hall should be basically functional and not a monument, originality in design is not precluded.

COURT AS A WHOLE

Fig. 1 Movement and access to internal spaces in the general trial court.

The American Courthouse: Planning and Design for the Judicial Process, The American Bar Association and The American Institute of Architects Joint Committee on the Design of Courtrooms and Court Facilities, The Institute of Continuing Legal Education, Ann Arbor, Michigan, 1973.

GENERAL TRIAL COURT

Trial Operations

Jury trials, whether civil or criminal, involve five general operations: opening preliminaries (including impaneling of the jury), opening statements, presentation of evidence by each side, closing statements, and deliberation and decision.

1. The opening preliminaries start with the bailiff's announcement that the court is in session and the naming of the presiding judge, who enters and calls the first case. The attorneys first have the opportunity to make motions in the case, then they signify that they are ready for trial. After the jury has been impaneled and sworn, an attorney may ask that all witnesses other than the parties be excluded from the courtroom. If the judge so rules, he informs the witnesses where they should wait. The court may recess a number of times, and it may adjourn to reconvene the following day or at some later time.

2. The prosecutor or the attorney for the plaintiff generally presents the first opening statement, followed by the defendant's opening statement. Each attorney tries to present the strong points of his case in his statement, defining the issues and describing the evidence he intends to present in support of his contentions. Motions may be made during or at the end of the opening statements.

3. The attorneys for each side then present their evidence. The prosecution in a criminal case, or the plaintiff in a civil action, goes first. Evidence consists of all exhibits and testimony by witnesses, including parties. Absent [sic] a priori stipulation on its admissibility, the opposing attorney may challenge the admissibility of any exhibit. The jury may be dismissed while the attorneys present their arguments to the judge on the matter, or the arguments may occur at the judge's bench or outside the courtroom. Each exhibit received in evidence is given an identifying number by the reporter or clerk.

When the attorneys request the isolation of witnesses, private and secure waiting facilities outside the courtroom are necessary. After each witness is called and sworn by the clerk, the attorney who called the witness proceeds with direct examination. The opposing attorney then cross-examines the witness and the first attorney may then examine on redirect.

4. Each attorney makes a closing statement to present the merits of his [her] case forcefully and persuasively. Although practices vary, the judge usually has had an earlier conference with the attorneys about the length of these statements and the content of instructions to be given to the jury. Generally, each attorney prepares the instructions which he [she] wishes the judge to give to the jury. The judge may use any of these or, in most jurisdictions, may frame his [her] own instructions. Opposing counsel may object to specific instructions given by the judge. A growing number of states are adopting "pattern" jury instructions, which are standardized expositions of points of law to be used in every case where they are applicable. Such instructions should reduce the number of inconsistent and conflicting decisions in the trial courts of the state and eventually reduce the number of appeals.

5. Jury deliberation and decision continues until agreement is reached or the jury informs the bailiff that it cannot agree upon a verdict. Deliberations can continue for days, and unless facilities are planned so that the trial courtroom can be utilized for other proceedings during this period, the space is not being used efficiently.

TABLE 1. Unit Space Requirements of the Courtroom

Participants	Furniture area per person, sq ft	Movement area per person, sq ft	Total area per person, sq ft
Judge	20-25*	25-30	45-55
Clerk	15-18	15-17	30-35
Reporter	8-9	3-6	11-15
Bailiff	8-9	3-6	11-15
Attorney	15-18†	17-22	32-40
Party	11-13	5-7	16-20
Witness	7-9*	8-11	15-20
Juror	4-5*	4-5	8-10
Press	6-7	4-8	10-15
Public	3-4	3-4	6-8

* Add a nonencroachment distance of 5-6 ft.

† Add 4-5 sq ft for a movable podium.

After the jury returns a verdict, the losing attorney may ask that the jury be polled; the judge then asks each juror if the verdict properly states his decision. Judgment may be entered on the verdict forthwith, or judgment may be reserved until the judge has ruled on post-trial motions filed by counsel.

Space Requirements

Table 1 shows the areas for movement and furniture (including working and seating surfaces) which each person in the courtroom requires. The nonencroachment distance of 5-6 feet for the judge insures a degree of privacy commensurate with his role. A nonencroachment distance surrounding jurors and witnesses helps prevent violation of the jurors' impartial role by attorneys and lessens the impact of attempts to intimidate witnesses.

Numerous cases involve several parties and more than one attorney for each side. Space should be provided for four attorneys and four parties, an area of 192-240 square feet. In addition, a space of 112-140 square feet must be provided for twelve jurors and two alternates.

Thirty jurors are usually called for examination (voir dire); if thirty spectators are assumed, the total public and observation seating area required would be 180-240 square feet, with perhaps an additional 50-75 square feet for the press. A total space of 534-695 square feet is required

to accommodate all active (304-380 square feet) and passive (230-315 square feet) participants. This does not include general circulation space.

Communication and Spatial Patterns

The four types of communications in every courtroom are visible, audio, movement of people, and document transfer. By studying the frequency and importance of communications, a communication pattern is developed for each person in relation to every other person in the courtroom. The communication pattern is then utilized to show how each person should be spatially related to every other person. The patterns for the four types of communications, together with the unit space requirements, provide the analytical basis for a courtroom plan.

A Total Communication System By combining the separate analyses of visual and audio communications, movement of people and document transfer, a total pattern of communications is achieved (Fig. 2). The attorneys and judge are the main nodes of communication, followed in importance by the witness and the jury.

Figures 3 and 4 are the final composite spatial disposition diagrams resulting from a superimposition of separate diagrams. These diagrams reveal that if the visual requirements of the active participants are met, most of the other requirements are fulfilled.

Fig. 2 A total communication system for jury trials.

Governmental and Public

COURTHOUSES

Fig. 3 Spatial disposition for jury trials, based on a total communication system (alternate A).

Fig. 4 Spatial disposition for jury trials, based on a total communication system (alternate B).

In Fig. 3 (alternate A) the bailiff can move unobtrusively to judge, witness, and jury; easily supervise and escort witnesses and jurors; run errands for the judge; and keep the public and press under constant surveillance. In Fig. 4 (alternate B), he has to cross the room to reach the jurors.

In both diagrams the witness is located within the private conversation zone of the judge. To keep him [her] out of this zone and still meet the visual requirements, the space around which the active participants are grouped must be expanded. Failing this, the judge's bench should be designed so that the end farthest from the witness box can be used for private talks between judge and counsel with the reporter present.

Only visual and audio requirements need be considered in the location of the public and press. No satisfactory visual location of the observation area permits it to fall wholly within the desirable audio zone, although alternate A is better in this respect than any other disposition.

Observation Space Problems The space allocated to public and press in Figs. 3 and 4 may not be sufficient for cases that attract a large attendance. Figures 5 and 6 show its possible expansion.

The ability to satisfy visual and audio requirements decreases as the observation space expands beyond its optimum position. With an extension sideways, the public and press move behind the primary participants and are less able

to see faces clearly. If the public and press space is extended around the rear of the jury box, observers would still be able to view all the other participants. If the observation space is extended around the rear of the attorneys' and parties' stations, the public and press would see the attorney only from behind when he addresses the court. Such extension would also conflict with any expansion of the area for attorneys and parties in cases involving several of each. Alternate B (Fig. 6) therefore appears more satisfactory for courtrooms requiring large observation seating capacities.

Providing a large public observation space in every courtroom to accommodate an occasional well-publicized case is unrealistic and expensive. Most courtrooms require only sufficient space to accommodate relatives and friends of the defendant or people directly related to the case.

In jurisdictions where the impaneling of jurors, including the voir dire questioning, is performed in the courtroom, there should be adequate space for the seating of prospective jurors. The observation area is the natural place for this purpose. If thirty persons are required from which to impanel a jury, the observation area should provide seating for this number plus some observers, perhaps a total of forty. If the jurors are impaneled outside the courtroom, twenty seats would be quite adequate for observers.

In each jurisdiction, average and maximum public attendance for each type of case should be recorded and analyzed to assist in the formula-

Fig. 5 Enlarged public and press areas for jury trials (alternate A).

Fig. 6 Enlarged public and press areas for jury trials (alternate B).

tion of space requirements for future facilities. Occasional cases for which a large public attendance is anticipated can be assigned to courtrooms equipped with larger public observation spaces. One judge writes: "With respect to courtrooms for jury trials, I believe they must be basically of one size. The need for larger space for the public during an important trial would have its drawbacks. Basically, we are interested in the litigants, their witnesses and relatives and friends—not to provide an amphitheatre for those interested in watching a particular procedure."

A recent survey indicates that most news reporters want a court location where they can clearly see and hear the primary participants; leave the courtroom with minimum disturbance; have adequate writing surfaces, an unobstructed frontal view of all participants and a clear close-up view of all exhibit boards; and be close enough to the witness to hear every word.

Because they fear it would set a precedent for excluding the press from the courtroom, most news reporters see little merit in seating the press in another room behind a one-way window with a view of the proceedings. However, there is some interest in an enclosed press area behind a one-way window which would permit the use of phones and possibly courtroom photography. A one-way window would give news reporters maximum freedom to converse and move about and enable them to have instant communication with their offices in order to meet deadlines. Some news reporters, on the other hand, think that a

courtroom should be designed primarily for the trial proceedings and that no special provisions should be made for the press.

In most general trial courtrooms today, the space ratio between the action area and the public observation space is approximately two to one, with the latter being a physical part of the courtroom. The public is usually placed behind the attorneys and parties as a visually integrated part of the courtroom.

If the observation space were separated from the courtroom by a glass wall and a sound system were installed, there would still be a possibility of visual distraction from the audience. This would not be the case, however, if one-way glass were used as the separating wall. Depending on the number of people to be accommodated, the observation area could be placed in two or more locations. Whatever its size and location, this area requires different spatial and other environmental considerations than does the courtroom action area.

Should closed-circuit television be accepted in a public trial, the spatial relationship between the public observation space and the courtroom would be revolutionized. Then the public observation space would no longer have to adjoin the courtroom, which could lead to several drastic design and planning changes.

- There would be a significant reduction in the size of the courtroom. Few jury courtrooms would need to exceed 1,500 square feet, and the area of nonjury courtrooms could be considerably smaller.
- In a multilevel courthouse, more courtrooms could be grouped together on each floor. Public traffic could be more readily separated from the traffic of courtroom participants; thus, more courtrooms on each floor would not necessarily mean greater traffic congestion.
- Public observation spaces could be centralized on the lower floors of a multilevel building, concentrating the public traffic to avoid overload of the vertical transportation system and minimizing unnecessary movement throughout the building.

Courtroom Accessibility

Participants entering the courtroom should be able to get to their respective locations as directly as possible, a goal best achieved by placing access points close to their locations (Figs. 7 and 8). The diagrams are not meant to pinpoint the exact location of each entrance, but simply to indicate its general position; nor is it implied that each type of participant should have a separate entrance.

Movement of participants from spaces outside the courtroom to their points of access should also be as direct as possible. The judge and the court staff, coming from their chambers and staff offices, should not have to go through the public areas of the courthouse to get into the courtroom. This is not merely a matter of convenience. Personal contact between jurors and the public should be avoided under all circumstances to minimize the risk of mistrial. Separate public, private, and security zones must be established in the courthouse, with similar zones of access to the courtroom.

The alternate plans show the judge, court staff, and jurors coming from their outside private zone and going directly to their stations within the courtroom. The public and the press should be able to enter their observation area directly from the public zone. Attorneys, parties, and witnesses

should be able to enter their waiting areas from the public zone and from there go directly to their stations in the courtroom. Prisoners should come directly through a separate security zone to a detention space near the bailiff's station.

NONJURY TRIALS, HEARINGS, AND ANCILLARY FUNCTIONS

The current trend in the court system is toward achievement of a speedier and more effective administration of justice. In the nonjury trial, participants are few and the operations are simple; in formal and informal hearings, the participants are even fewer and the operations simpler. Thus, the physical requirements of these proceedings are modified accordingly from those of the jury trial.

Courtrooms equipped for full jury trials can, of course, be used for nonjury trials and hearings. A flexible arrangement of furniture, with front rows which can double as an attorneys' table is desirable.

Objectives

Nonjury Trials In comparison with jury trials, nonjury trials reduce the emotional and monetary costs; they also require less time for disposition. The nonjury trial encourages a substantial reduction in the real or apparent hostility of attorneys and allows the judge to dispose of many more

disputes. The time for impaneling a jury is eliminated, and opening and closing statements can be much briefer since the judge is presumed to be an expert. Arguments can be heard immediately because repeated recesses for discussion out of hearing of the jury are not required. There is no need for the preparation of instructions to the jury, and the time for jury deliberation and decision is eliminated.

The needs of news reporters and the general public are essentially the same as in jury trials. However, there is generally much less public interest in nonjury trials; the physical facilities for news reporters and public observers can be reduced without impairing any privileges.

Hearings Whether a hearing is formal or informal, its primary characteristic is variety. There is a broad spectrum of legal proceedings ranging from adoption to bankruptcy to arraignment to general motion practice. There is an equivalent range in the extent to which hearings can dispose of cases. A hearing may result in final disposition, temporary resolution, resolution of one part of a larger proceeding or a temporary postponement. The degree to which a hearing is an adversary proceeding can also range widely within the same type of hearing, whether formal or informal. The same is true of the number and types of persons involved, as well as the degree of simplicity or complexity of their activities. Despite this

Fig. 7 Optimum access to the jury trial courtroom (alternate A).
a. If jury impaneled in courtroom. b. If jury impaneled outside courtroom.

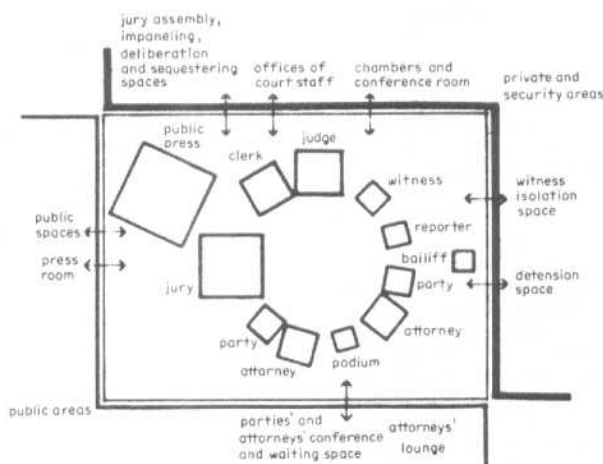

Fig. 8 Optimum access to the jury trial courtroom (alternate B).

Governmental and Public

COURTHOUSES

diversity, certain general observations can be made about the objectives of both formal and informal hearings.

Formal hearings require flexibility seasoned with appropriate solemnity and restraint. Flexibility is needed because of the variety of matters which may come before the presiding officers, who may or may not be judges. Appropriate solemnity and restraint are needed because of the hostility which may be present.

Informal hearings require flexibility seasoned with kindly or businesslike responses from the presiding officer. The hearing should aim at maximum interchange within a quasiprivate environment. Informality can be achieved without loss of dignity and with minimum restraint on all participants, including the presiding officers. Flexibility is required because of the great variety of legal proceedings heard informally. When personal problems are involved, an atmosphere of calm and friendly concern is needed. For fiscal matters like bankruptcy or small claims, an atmosphere of efficiency and businesslike involvement is desirable.

Operations

Nonjury Trials The general operations of the nonjury trial include the opening preliminaries, opening statements, presentation of evidence, closing statements, and deliberation and decision by the judge.

With the elimination of a jury, activities are simplified. Opening preliminaries involve only convening of the court and determining that all parties or their representatives are ready for trial. Opening and closing statements tend to be briefer. Presentation of evidence may evoke objections, but these can be argued and ruled upon immediately by the judge. Closing statements are usually confined to questions of law raised by the case. The judge either gives his decision immediately or takes the case under advisement. In the latter instance, he often asks for briefs from each side. After the decision, post-trial motions are filed and later considered by the judge, and a judgment, final unless appealed, is given.

Hearings Certain hearings are almost indistinguishable from trials without a jury and, further, the dividing line between formal and informal hearings is as nebulous as the line of demarcation between informal hearings and conferences.

Hearings, both formal and informal, may be related to a trial or may be used as a substitute for a trial to dispose of cases in certain specialized legal proceedings involving, for example, minors, incompetents, injunctions or probate matters.

Most hearings related to trials involve motions, which are typically requests that the court decide a single issue such as jurisdiction or a change of venue, discovery requests, a motion for a new trial or postponement of sentencing. Motions can be made verbally at the hearing or presented in writing, and arguments can be verbal or in the form of briefs. Decisions can be expressed as an opinion or a verbal assent or dissent.

The operations in the formal hearing include the opening preliminaries; presentation and argument, in which the presiding officer may play an active role; and decision by the presiding officer. They are not too different from nonjury trials—somewhat less elaborate but still retaining the formal qualities of a trial. The presiding officer may be a judge or a court officer such as a referee in bankruptcy cases. Typically, a clerk and a court reporter make an official transcript of the proceeding.

Opening preliminaries include convening the hearing and determining that all necessary parties or their representatives are ready to proceed. Depending on the type of hearing, the presiding officer may actively participate in examination of a party or witness or may sit as a disinterested overseer of the proceeding. In the latter instance, the hearing operates in much the same fashion as a nonjury trial. Decision by the presiding officer may be made immediately, or he may take the matter under advisement and hand down a decision at a later date.

Informal hearings are similar, but less stylized and often private. Attorneys are frequently not present and usually a small number of persons attend. Very often court reporters are not necessary and in some instances the presiding officer does not use a clerk or bailiff. Official orders are either prepared and signed during the hearing by the presiding officer or prepared, signed, and transmitted at a later date.

Exploration of the problem and its possible solutions may involve ordered presentations by the parties or their attorneys, or it may only be a conversation between the presiding officer and someone who has a problem. The problem can be extremely complicated, or it may only require a necessary signing of a document. Usually, the decision of the presiding officer is made immediately.

Requirements of Nonjury Trials and Formal Hearings

Each nonjury trial and formal hearing exhibits different characteristics, but even in the largest metropolitan areas it is impractical to design a formal hearing room to serve each type of case. Instead, it is more practical to have one room which can be adapted to fewer participants and differing degrees of formality. Furniture should be movable and adjustable in height, so that its arrangement can conform to the degree of formality. Adjustable partitions and ceilings allow for change in the size and character of the room as needed.

Except for the elimination of jury activities and the space required for the jury box, the activity, space, and communication (visual, audio, movement, and document transfer) relationships in nonjury trials and formal hearings are the same as in jury trials. There is only a slight variation in the degree of importance of the bailiff.

Composite Spatial Disposition As might be expected, the composite spatial disposition for communications (Fig. 9) is much the same as that for the jury trial (Figs. 3 and 4). The absence of a jury enables the participants to be closer to each other, and the attorneys and parties can be moved toward the judge. The diameter of

Fig. 9 Spatial disposition based on a total communication system (nonjury trials, formal hearings)

Fig. 10 Location of visual equipment and display board (nonjury trials, formal hearings)

Fig. 11 Access to the courtroom from related spaces (nonjury trials, formal hearings)

the trial area is also reduced by approximately 5 feet.

The use of movable furniture in the trial area below the judge's bench will allow rearrangements to conform to proceedings of differing complexity and formality. With fewer participants, the distance between them can be reduced or they can be brought into a less formal relation to each other.

Figure 10 shows the location of television cameras related to a video tape system. The camera behind the clerk is capable of panning 180 degrees while the second camera is fixed on the judge and the witnesses. The only variation from the jury trial is that the exhibits display board is now within the range of the first camera. Figure 11, showing courtroom access, uses the same criteria as Figs. 7 and 8.

Requirements of Informal Hearings

Compared with trials and formal hearings, everything is simplified and condensed in the informal hearing. Frequently, the only participants are the judge or hearing officer, the clerk, and the party or parties, although attorneys or other representatives of the parties, a court reporter, and witnesses also attend at times. Even if open to the public and press, the degree of public interest

is so low that observers can readily be accommodated with a few extra chairs.

The communication patterns among participants in such hearings are similar to those in trials, but simplified by the absence of the bailiff, jury, public, press, and others.

The smaller number of people and the informality require a more intimate arrangement of participants. A spatial disposition for visual communication based on the maximum visual angle of 150 degrees reduces the distance between the judge and the attorneys to less than 15 feet and between the court reporter and the farthest party to less than 25 feet (Fig. 12).

Beyond the maximum audio angle of 140 degrees, speech intelligibility reduces rapidly. In Fig. 13, optimum audio conditions exist within the

Fig. 12 Spatial disposition for informal hearings, based on visual requirements

Fig. 13 Spatial disposition for informal hearings, based on audio requirements

area enclosed by the broken dotted line, the result of drawing 32-foot arcs from the major participants.

Movement during informal hearings is minimal, although sometimes the judge and the attorneys may discuss matters privately at the bench outside the hearing range of the parties and witnesses, with the reporter also moving to the bench. Occasionally attorneys and their respective clients may have private conferences. For the most part, however, all remain seated throughout the proceedings (Fig. 14).

Spatial disposition based on the transfer of documents between participants is shown in Fig. 15. Again the attorneys are the most active participants, transferring documents and exhibits to the judge, clerk and witnesses. Figure 16 shows the composite spatial disposition of participants. The attorneys and parties are placed in front of the judge who is flanked on one side by the clerk and by the witness, if any, on the other. The court reporter is adjacent to the witness and is approximately equidistant from the judge and the attorneys. This results in a generally elliptical

Fig. 14 Spatial disposition for informal hearings, based on movement

Governmental and Public
COURTHOUSES

Fig. 15 Spatial disposition for informal hearings, based on document transfer

Fig. 16 Spatial disposition for informal hearings, based on a total communication system

Fig. 17 Access to the informal hearing room from related spaces

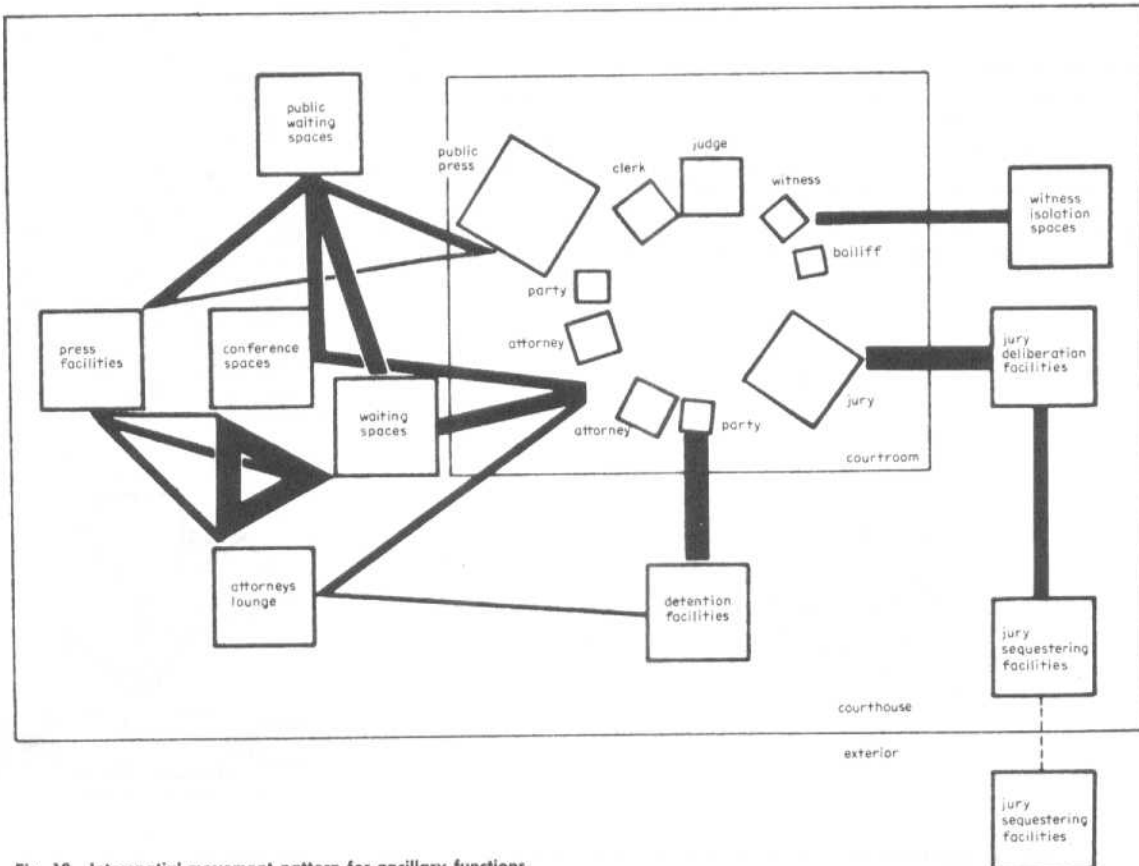

Fig. 18 Interspatial movement pattern for ancillary functions

shape, but where witnesses and a reporter do not attend, a flexible furniture arrangement permits parties and their representatives to be moved closer to the judge.

To emphasize his role, the judge's bench should be raised, but not so high as to prevent informality in the proceeding. Since all participants remain seated when speaking, it is sufficient for the judge to be one step above the eye level of the other participants. The nonencroachment distance between attorneys and the judge and between the witness and attorney during examination should be maintained at a minimum of 5-6 feet.

Ideally, there should be three separate points of access into the informal hearing room, as shown in Fig. 17. The judge and the court staff,

including the clerk and the court reporter, should have separate private entrances into the room. The attorneys and the parties can enter either from their waiting spaces or from the public waiting space. Witnesses involved in informal hearings do not normally require isolation, so seating space could be provided for them within the room.

Ancillary Functions

Several ancillary functions primarily identified with trials and hearings may also have some relation to other court functions. Conferences between attorneys and parties call for conference rooms. Attorneys should be able to relax and work in the privacy of an attorneys' lounge, while the public and news media should have separate facilities. When witnesses are isolated, they are the responsibility of the bailiff and must remain in witness isolation spaces until called to testify. Temporary detention of the accused or defendant in detention facilities is the responsibility of the law enforcement officers, but the security and safety of jurors during jury deliberation and sequestering are the responsibility of the bailiff.

Analysis of movement among these activities shows their relative importance to be in the following descending order: trial and hearing, waiting, working and relaxing, public waiting, conference, news reporting, jury deliberation, detention, witness isolation, and jury sequestering.

Figure 18 shows the interspatial movement pattern for ancillary functions. Witness isolation and jury deliberation and sequestering spaces should be located in close proximity to the witness stand and to the jury box, respectively. The other ancillary activities are related to each other and should be grouped together near the courtroom. The attorneys' lounge should preferably have a separate access into the courtroom and be readily accessible to the detention space. In addition, the detention space should be close to the defendant's station in the courtroom, with direct access. Press facilities should be located near the courtroom and reasonably near the conference and waiting spaces. The public waiting space should provide access to the conference and waiting spaces, press facilities and the attorneys' lounge, as well as to the public observation space in the court-

room. If audiovisual devices are used, however, the public observation space does not have to be located in the courtroom. Table 2 shows unit space requirements for each ancillary activity both on a per person basis and as modules for minimum requirements.

TABLE 2 Unit Space Requirements of Ancillary Functions

Space	Area per person, sq ft	Area of combined spaces, sq ft
Conference space	20-27	80-108 (4 persons)
Waiting space	13-20	260-400 (20 persons)
Witness isolation	44-63	
Attorney's lounge		
Lounge space	13-20	130-200 (10 persons)
Work space	44-63	
Press room		
Interview space	20-25	200-250 (10 persons)
Offices	69-75	

THE DISTRICT COURT

Court spaces most frequently required in federal buildings are for the district court which holds sessions in the principal cities of its judicial district and generally has its headquarters in the largest or most centrally located city in the district.

Part 1. Description

Jurisdiction The district court is the federal court of original jurisdiction where cases are given their initial trial. Each state comprises at least one judicial district and, depending upon the volume of business and its geographical distribution, a state may be divided into two or more judicial districts.

Spaces Required With a few exceptions, a United States district court sits at more than one place within each judicial district. The following spaces are always required:

- Courtroom
- Judge's suite
- Court officers quarters
- Petit jury rooms
- Grand jury suite
- Witnesses' room

In some instances, a district court library, jurors' assembly room, press room, pretrial hearing room, and attorneys' conference room will also be required.

Court Officers Requiring Quarters At each place of holding court, space will be required for the following officers:

- United States district judge (one or more, depending upon the volume of business within the district)
- Clerk of the court
- United States attorney
- United States marshal
- Probation and parole office (one or more)
- Court reporter (one or more)

Additional Offices at Major Installations Wherever a major installation of the district court is required, facilities will be needed in it for the following additional officers, if specified:

- Referee in bankruptcy (one or more)
- United States commissioner
- Jury commissioner

Space Arrangements in District Court Suite Certain parts of the court must be closely connected. Courtrooms and their related rooms should ordinarily be above the first floor. In multistory buildings, all of the court activities should be located on consecutive floors. It is not desirable to place agencies unrelated to the court on the same floor with it. The need for simple, direct circulation for the public and for the court officers will influence the location and arrangement of the units of the court.

GSA Handbook, Public Buildings Service, General Services Administration, Washington, D.C.

Part 2. The District Courtroom

Location The court's activities revolve around the courtroom, so it should be centrally located. Spaces for the officers of the court should be placed with regard to their functions in the courtroom and their responsibilities to the judge. (Figs. 1 to 3).

Illumination Natural lighting may be restricted to auxiliary offices, the courtroom itself having no outside exposure.

Dimensions The minimum size of a district courtroom is 38½ ft in width by 58½ ft in length. The ceiling height of a courtroom should be proportionate to its size and to the requirements of proper illumination, ventilation or air conditioning, and acoustics. In a large installation with many courtrooms, most of them should be of minimum size. One or more courtrooms with additional space for the audience may be necessary to accommodate trials that attract the public and are attended by many representatives of the press.

Courtroom Entrances

Public Entrance. This is located at the end of the courtroom opposite the judge's bench and fitted with double doors swinging out into a courtroom lobby.

Jury Entrance. This entrance should permit the jury to pass directly from the courtroom to the jury rooms, preferably without crossing the courtroom or passing through any public corridor or space. If the prisoners cannot use the jurors' entrance door, provide a special entrance through which they may be taken to the detention cells.

Side Entrance. Provide an entrance, for attorneys and press reporters, to the courtroom area in front of the railing and benches for the public.

Coat Closets For the use of attorneys, provide one or more coat closets off the judicial end of the courtroom to accommodate not less than 20 coats. For the jurors selected, provide a coat closet or alcove either immediately off the courtroom or off a secondary lobby which is not accessible to the public.

Furniture

Built-in Furniture. The jury box shall accommodate 14 jurors and should be located at the judge's left. The following items must be provided:

- 1 Judges' bench and witness stand
- 1 clerk of court desk and court reporter
- 1 jury box
- 12 benches with gate and railings

Fixed Chairs. The jury type courtroom must accommodate the following fixed chairs:

- 1 armchair for witness stand—rotary, fixed-pedestal
- 14 armchairs for jurors, rotary—fixed-pedestal

Movable Furniture. Limited to the following:

- 3 judges' chairs
- 1 clerk of court armchair—rotary
- 1 court reporter armchair—rotary
- 1 lectern, Fig. 1
- 10 attorneys' armchairs—rotary
- 10 armchairs for general use
- 2 attorneys' tables—120 by 48 in.
- 1 press reporters' table—120 by 48 in.
- 1 flagstaff—shaft top 9½ ft above floor

Part 3. Judge's Suite

Components Judge's entire suite includes the following rooms:

- Judge's office
- Judge's library
- Judge's reception room
- Judge's toilet
- Judge's coat closet
- Secretary and reception room
- Crier's vestibule
- Law clerk's office
- Coat closet
- Supply closet

Location The judge's suite must be located adjoining the courtroom. A corner office for the judge is generally preferred, but it may be necessary to place it elsewhere to get maximum freedom from street noises. See Fig. 4. Locate the judge's office to provide access to the bench either directly from his office or through a private passage, so that the judge will not have to go through any public space. The judge's office must connect with a corridor, so that he may enter or leave without passing through any other office.

Entrances The entrances required for circulation within the judge's chambers are shown on Figs. 1 and 4. Where several courtrooms are grouped on a floor, judges may pass to the courtrooms through a common private corridor. In multistory buildings, it is desirable to have the judges' suites adjacent to the courtrooms so that the judges do not have to go through public spaces or use public elevators when going to or from court. Public entrance must be provided for the secretary's office.

Judge's Office

Area and Furniture. As informal pretrial hearings are often held in the judge's office, the minimum area shall be 750 sq ft.

Height. Ceiling height shall be not less than 9 ft.

Shelving. Usable wall space of the judge's suite shall be lined with flush, adjustable wood bookshelves 10 in. wide and extending from the floor to the top of the doors. The walls above shall be furred out to the face of the shelves.

Clock. Install a wall electric clock on a wall visible from the judge's desk and not hidden by a lighting fixture.

Governmental and Public

COURTHOUSES

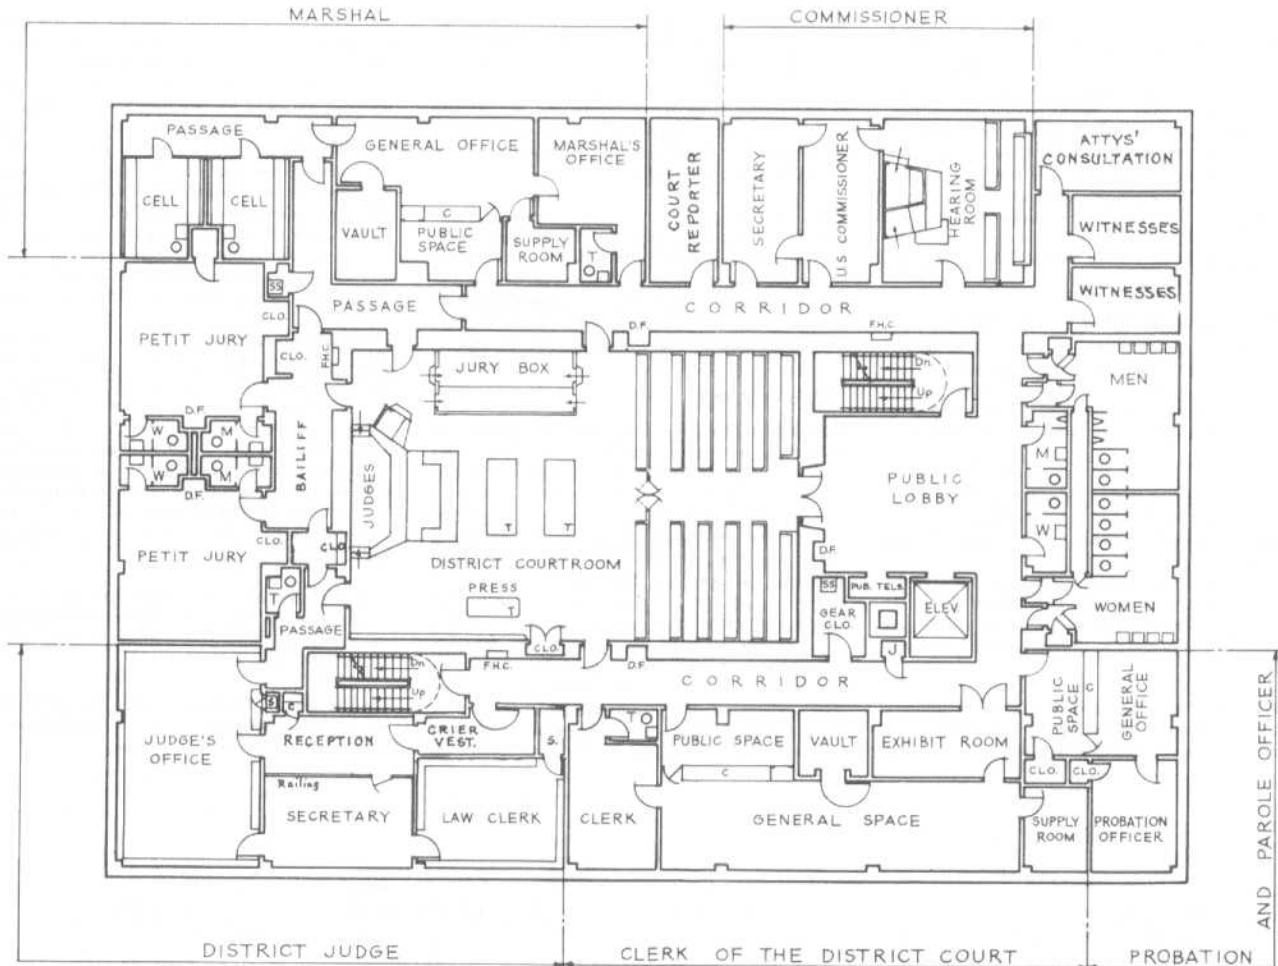

Fig. 2 District court plan, first floor.

Entrances If there are two or more jury rooms, they may open into a common lobby under the control of a bailiff.

Signaling Equipment In each petit jury room, install equipment to operate a flashing signal in the bailiff's lobby and in the courtroom.

Panic Exits If entrance to a jury room is directly from a common lobby, such jury room or common lobby must have a second exit door of panic type, equipped with suitable panic hardware, local alarm signal, and explanatory sign on the jury side of the door.

Soundproofing The walls of the jury room must be soundproofed, as the jurors' discussions would otherwise be audible in adjoining rooms. The jury room should have an acoustic ceiling.

Auxiliary Occupancy When court is not in session, the jury room often serves as a waiting room, a roll-call room, or a conference room.

Part 5. Witness Room

Locations This is for the use of witnesses waiting to testify before the court and should be located as near the courtroom as possible, preferably on the same side as the marshal's office. A deputy marshal or bailiff calls the witnesses into the courtroom. Refer to Fig. 2.

Area The witness room shall have a minimum area of 200 sq ft.

Auxiliary Uses When the court is not in session the witness room may be used as a conference or committee room.

Part 6. Jurors' Assembly Lounge

Three Courtroom Requirements This lounge may be required if there are two or more courtrooms. The size of the lounge will be determined by allowing 15 sq ft per occupant. The lounge shall have a private toilet for men and also one for women. Provide an entrance from the public corridor and a drinking fountain. When a jury commissioner's suite is required, the jurors' assembly lounge forms part of that suite, but it need not be adjoining or adjacent. Telephone recesses and cloak room should have direct access from this lounge.

Furniture The number of selected jurors will determine the number of varied style chairs, tables, magazine racks, etc., to be installed in this jurors' lounge.

Part 7. Grand Jury Suite

Description, Location, and Components The grand jury is impaneled by the court and consists of not less than 16 nor more than 23 jurors. The

grand jury hears evidence presented to it and conducts investigations to determine if charges or violation of federal criminal statutes shall be prosecuted. It is presided over by a foreman, named by the court, and usually the cases considered by it are presented by the United States attorney. Outsiders must not be able to overhear or observe grand jury proceedings. The plan of the grand jury suite shown, Fig. 5, indicates the relationship of the rooms and the entrances required. The grand jury suite includes the following rooms:

- Grand jury room
- Witnesses' room
- Bailiff's vestibule
- Coat closet and toilet for men and women

Grand Jury Room The grand jurors' chairs are in either three or four rows, depending upon the width of the room. This room shall have a minimum area of 600 sq ft to accommodate

- 23 jurors' armchairs—rotary and fixed
- 1 table—96 by 42 in.
- 1 table—54 by 42 in.
- 6 armchairs
- 1 drinking fountain

Witnesses' Room This is for the use of witnesses until called by the bailiff to testify in the grand jury rooms. The witnesses' room shall have a minimum area of 300 sq ft.

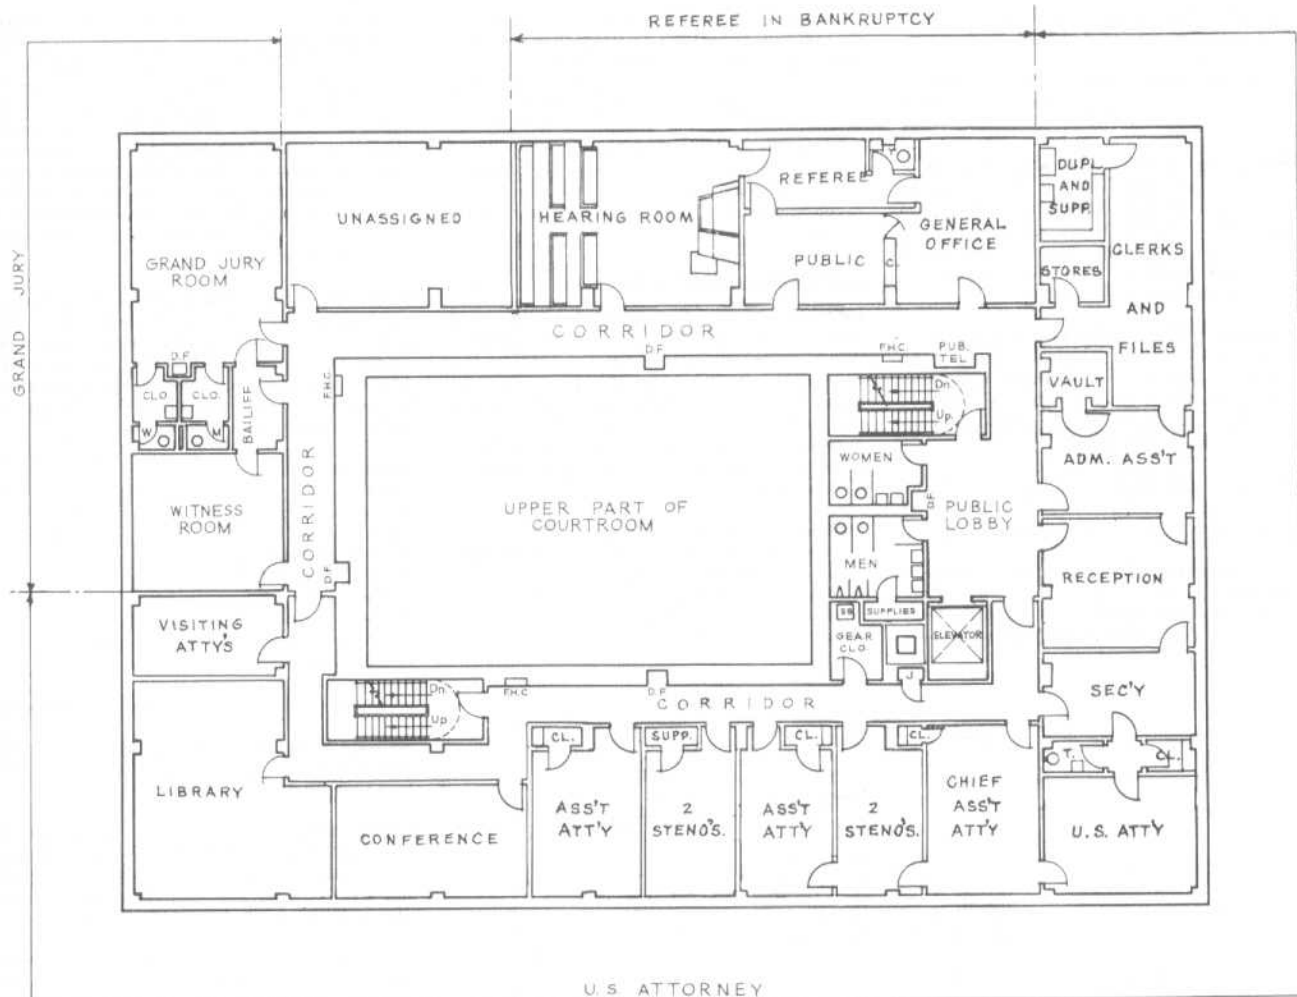

Fig. 3 District court plan, second floor.

Bailiff's Vestibule This shall have a minimum of 40 sq ft and must accommodate a desk and one armchair.

Coat Closets—Toilets for Men and Women Figure 5 shows a desirable combination of coat closets and toilet rooms, but a common coat closet or alcove and separate toilet rooms are acceptable.

Part 8. United States Attorney

Duties and Location The United States attorney represents the government in all cases, both civil and criminal, to which the government is a party or in which it has an interest. Since much of the time of the United States attorney and the assistant attorneys is spent in the courtroom, their offices should be located convenient to it, but not necessarily on the same floor.

Components The United States attorney has a headquarters at some designated city in the judicial district, not necessarily the same city where the judge's headquarters are located. His suite in a courts building varies in size in accordance with the amount of work he must handle. A typical suite, Fig. 3, will include the following.

United States attorney's office
Coat closet and toilet
Reception room
Secretary's office
Chief assistant, United States attorney's office
Assistant, United States attorney's office
Stenographer's office (two stenos each)
Conference room
Visiting attorneys' room
Library
Administrative assistant's office
Vault
Clerks and files room
Supply room—general—duplicating
Storage room

United States Attorney's Office The office of the United States attorney shall have a minimum area of 300 sq ft.

Reception Room In large installations a public reception room, readily accessible to callers, shall be provided. It adjoins the secretary's office and should be located between the office of the United States attorney and that of the administrative assistant. Refer to Fig. 3. The minimum area of the reception room shall be 300 sq ft. It shall be planned to seat visitors and to permit control of intercommunicating doors by the receptionist.

Secretary's Office In metropolitan areas where there is a great deal of work, the United States attorney may require the services of a private secretary, whose office usually is located between the office of the United States attorney and the reception room.

Chief Assistant United States Attorney's Office The office of the chief assistant United States attorney shall have a minimum area of 250 sq ft. Locate it adjoining the office of the United States attorney.

Conference Room The conference room shall have a minimum area of 250 sq ft. A large installation may require several conference rooms, located for the convenient use of the attorneys. This room should be sound treated.

Assistant United States Attorneys' offices Offices of the assistant United States attorneys should be adjacent to each other and convenient to the chief assistant United States attorney. Each office shall have a minimum area of 180 sq ft.

Library The library is used by all of the attorneys in the suite and therefore should open on a corridor.

Administrative Assistant's Office The office of the administrative assistant should be located adjoining the reception room on the side opposite

COURTHOUSES

the United States attorney's office and shall have a minimum area of 230 sq ft.

Vault A vault for the administrative assistant, opening into his office, shall have a minimum size of 6 by 9 ft.

Work and Supply Room A general work and supply room convenient to the administrative assistant's staff shall have a minimum area of 50 sq ft. It may be necessary to provide a separate room with electrical outlets for a mimeograph machine, photostat machine, or other duplicating equipment.

Stenographers' Office Provide administrative assistant/stenographers' office between the offices of assistant United States attorneys, allowing a minimum area of 100 sq ft per desk. Generally there will be a ratio of two stenographers for three attorneys.

Clerks and Files Room The room for the clerks and files shall adjoin and connect with the administrative assistant's office.

Smaller Installations United States attorney's suites differ in size and requirements in accordance with the work in the district. They may be as small as three rooms in cities where

court is held for a very short period or where no assistant United States attorney is regularly stationed. Where no United States attorney is regularly stationed at a place of holding court, his offices will not have a private toilet or coat closet and the rooms may be used for conference or committee rooms when court is not in session. Room sizes will average about 200 sq ft each and furniture will correspond with that of similar rooms in a major installation.

Part 9. United States Marshal

Duties The United States marshal is charged with the custody of prisoners and their production in court, the maintenance of order in the courtroom, the service of processes, the appearance of witnesses, the collection and disbursement of certain monies and fees, the custody of certain property in the possession of the court, and other special duties assigned by the court.

Location The marshal's suite should be so located with relation to the courtroom that prisoners can pass directly to it from the detention cells without exposure to public contact or view. If the suite is located one floor above or below the courtroom, a private stair

which offers no opportunity for escape must be provided for prisoners. In multistory buildings with courtrooms on different floors, a private elevator to transport prisoners from a lower floor or basement entrance to the marshal's detention cells and to and from the courtrooms is usually required. A freight elevator may often serve in lieu of a private elevator for this purpose. On large installations, the detention cells may be put in the basement. In that case, no additional detention cells are provided on other floors.

Components The United States marshal has a headquarters at some designated city in the judicial district, not necessarily the same city where the judge's headquarters are located. The marshal's suite varies in size according to the amount of work in the district. A typical suite for large installations includes:

Marshal's office
Toilet
General office
Vault
Bookkeepers' office
Deputy marshals' office
Interviewing room
Fingerprinting room
Detention cells for men and for women
Holding cells
Storage room
Evidence storage room (may be in basement)

Marshal's Office This shall have a minimum area of 300 sq ft. Provide a private toilet of not less than 30 sq ft.

General Office Provide a general office with a minimum area of 500 sq ft. The public space is separated from the rest of the general office by a counter and gate. The public space should have a minimum width of 8 ft.

Vault Opening into the general office, provide a vault with a minimum area of 100 sq ft. and accommodating a money safe. Locate the vault so that the interior is not visible from the public space.

Bookkeepers' Office Provide a bookkeepers' office adjoining the general office with a minimum of 300 sq ft. One desk is provided for each occupant.

Deputies Adjacent to and connected with the bookkeepers' office (by passage if necessary), provide an office with a minimum area of 300 sq ft for the marshal's deputies. One desk is provided for each occupant.

Fingerprinting Room Provide a fingerprinting room with a minimum of 120 sq ft adjoining and connecting with the deputies' office. In the smaller offices, the fingerprinting cabinet and lavatory may be placed in the deputies' office and the fingerprinting room omitted.

Interviewing Room Provide an interviewing room with a minimum area of 150 sq ft, located so that prisoners can be brought from the detention cells as directly as possible. The room shall accommodate one table and four side chairs.

Detention Cells for Men and for Women

Cells for Men. Usually, provide two detention cells with observation passage. The cells shall be not less than 10 ft wide and be large enough to accommodate the maximum number of prisoners detained at one time. The size of a cell shall be determined by allowing for each prisoner a minimum of 25 sq ft.

Fig. 4 Judge's chambers, district court.

Fig. 5 Grand jury rooms.

Cells for Women Prisoners. Similar to detention cells for men.

Observation Passage. An observation passage at least 4 ft wide shall be located along the exterior wall of the building and be separated from the cells by a prison-type grille partition. The entire cell must be visible from the observation passage.

Holding Cells If required, provide holding cells for projects with three or more courtrooms. They should be located in back of the courtrooms near the prisoners' entrance.

Supply and Storage Room Provide a supply and storage room of required size convenient to the deputies' office.

Evidence Storage At times marshals have custody of bulky evidence, requiring a large storage area. A storage room (preferably in the basement) of 300 sq ft minimum should be provided.

Smaller Installation This suite will require fewer and perhaps smaller rooms than the headquarters suite in the same district, but the arrangement and relationship of its rooms will be similar to that of the corresponding rooms in a major installation.

Part 10. Clerk of the District Court

Duties The clerk is the administrative officer of the court. He receives cases for filing in the court, maintains the records of its proceedings

and actions, organizes its calendar, receives and disburses its money, and gives information to attorneys and interested parties regarding the disposition of cases as recorded in his office.

Location It is desirable to locate the clerk near the courtroom and convenient to the judge. In multiple courts the clerk should be easily accessible to the public.

Components The offices of the clerk of the court vary in size and number in accordance with the volume of business. The rooms include:

- Clerk's office and toilet
- Chief deputy clerk's office
- General office, with public space and files
- Examination room
- Supply room
- Work room
- Vault
- Exhibit room
- File rooms as required
- Naturalization clerk's office, with public space

Clerk's Office This shall have a minimum area

of 500 sq ft and be connected with a private toilet with a minimum area of 30 sq ft.

Deputy Clerk's Office This shall have a minimum area of 300 sq ft and be located between the clerk's office and the general office.

General Office with Public Space The size of the general office ordinarily will be determined by the number of desks, tables, and file cases used. But if it requires so many cases for active files that they would cause the general office to be disproportionately large, provide additional file rooms. Preferably they should be connected to the general office; but if located on adjacent floors, provide direct stairways and dumbwaiters. The public space is separated from the rest of the general office by a counter with one or more gates. The public space shall have a minimum width of 8 ft. In a very large general office, the counter will be U-shaped or L-shaped to accommodate the required length. Provide a cashier's grille with returns on the counter. Refer to Fig. 6.

Examination Room This is provided for attorneys and others who are permitted to inspect the

Fig. 6 Clerk of the district court's suite (small installation).

Governmental and Public

COURTHOUSES

records. It shall have a minimum area of 150 sq ft and be connected to the general office.

Supply Room This should be close to the general office and have a minimum area of 100 sq ft.

Work Room This should be near the supply room. It shall have a minimum area of 300 sq ft. The clerk of the court may install a photostat machine with developing equipment and other duplicating machines that will require water, waste, and electrical connections.

Vault The vault, which holds a money safe, shall open into the general office and be planned to prevent public view of the interior. It shall have a minimum area of 80 sq ft, lined with steel shelving in sections 3 ft long and 12 in. wide.

Exhibit Room This shall have a minimum area of 250 sq ft. Entrance shall be from a corridor through double doors. The portable blackboard for courtroom use is usually stored in this room.

Smaller Installation This suite will require fewer and smaller rooms, but the rooms will be similar in character and relationship to corresponding rooms in a major installation. Refer to Fig. 6.

Naturalization Clerk's Office, with Public Space If an office for the naturalization clerk is required, it should be adjacent to the general office of the clerk of the court. The office shall have a minimum area of 400 sq ft, with a public space.

Part 11. Jury Commissioner

Duties and Components of Suite The jury commissioner, together with the clerk of the court, selects the persons who are eligible to serve on the grand and petit juries. Quarters for this officer are ordinarily not required except in major installations. A typical plan, Fig. 7, for a jury commissioner's suite in a major installation, will contain:

- Jury commissioner's office
- Examination room
- Jurors' assembly room
- Men's and women's toilets
- File room

Jury Commissioner's Office This shall have a minimum area of 250 sq ft, a width of 15 ft. and a direct entrance from the public corridor.

Examination Room This shall have a minimum area of 200 sq ft and connect to the jury commissioner's office.

Jurors' Assembly Room When quarters for the jury commissioner are required the jurors' assembly room should be part of his suite; but the room is frequently required as a separate unit, when no provision is made for a jury commissioner. It shall have toilets for men and women and a centrally located drinking fountain.

File Room This shall have a minimum area of 150 sq ft and be located adjacent to the jury commissioner's office.

Part 12. United States Commissioner

Duties The commissioner is a magistrate who exercises certain judicial functions and before whom persons are arraigned immediately

after arrest. He holds preliminary hearings of prisoners to determine whether they shall be held for the grand jury, discharged, or released on bail. He issues warrants and writs, fixes bail, and sometimes handles juvenile cases.

Location and Components The preferred location of the commissioner's suite is near the freight elevator or the prisoners' elevator. The suite, Fig. 8, need not be on the same floor as the courtroom. Usually it will include:

- Hearing room
- Commissioner's office
- Secretary's office (required only in larger jurisdictions)

Hearing Room This shall have a minimum area of 400 sq ft and accommodate:

- 1 Built-in combination bench, witness stand and attorney's table, built-in benches to seat a minimum of 16 persons
- 1 rotary armchair, fixed-pedestal—for witness
- 1 judge's chair—for the commissioner
- 5 armchairs
- 10 side chairs

Commissioner's Office This shall have a minimum area of 200 sq ft and adjoin and connect with the hearing room and the secretary's office.

One-Room Type In certain jurisdictions, the work of the commissioner may be insufficient to justify a separate hearing room and then only a single office of not less than 250 sq ft will be required.

Part 13. Probation and Parole Officer

Duties The probation and parole officer supervises the probationers referred to him by the court and the persons released on parole from

Fig. 7 Jury commissioner's suite.

Fig. 8 United States commissioner's suite.

penal institutions by the Department of Justice. For a stated period the probationer or parolee is required to report to the officer at specified intervals. He confers with the officer, who helps him solve his problems and adjust himself to society. To aid the judge in determining a sentence, the officer, when requested by the judge, makes presentence investigations of persons convicted of violations of the law.

Location and Components The suite should be located where it is accessible to the public by elevator or stairs, and preferably near the marshal's office, but not necessarily on the courtroom floor. The number of rooms in a suite varies with the amount of work handled by the officer. See Figs. 9 and 10. A suite may consist of the following:

Office for the probation and parole officer
Offices for one or more assistant officers
General office, with public space
File room
Supply closet or supply room

General Office with Public Space This shall have a minimum area of 275 sq ft when there are no assistant officers and 350 sq ft when there are one or more assistant officers.

Office of Probation and Parole Officer This shall have a minimum area of 200 sq ft. In an office staffed by two or more officers, the area for the chief may be increased. The office should connect

to the general office. In the case of a one-man office, it is desirable but not mandatory for the probation and parole officer to be able to pass directly from his office to the public corridor. Where there are two or more assistant officers, it is mandatory that each officer be able to pass directly from his office to the public corridor.

Offices for Assistant Probation and Parole Officers Each of these shall have a minimum area of 200 sq ft.

File Room This will be required only when there are two or more assistant probation and parole officers. It shall have a minimum area of 14 sq ft of file space for each assistant.

Part 14. Referee in Bankruptcy

Duties The referee conducts hearings, holds conferences, makes findings, and reports to the judge the findings and disposition of bankruptcy cases. Refer to Figs. 11 and 12.

Full-Time Referee, Chief Clerk and Two or Three Assistant Clerks

Components. The referee's work varies in the different districts, and the rooms and personnel in each office will vary accordingly. The referee's suite, Fig. 11, generally will include the following rooms:

Hearing room
Referee's office (with toilet)
General office with public space
Chief clerk's office
File room
Trustees' room

Hearing Room. This shall have a minimum area of 600 sq ft, be conveniently accessible to the public, and accommodate:

- 1 built-in combination bench and witness stand
- 1 judge's chair
- 1 armchair for witness, rotary, fixed-pedestal
- 2 attorneys' tables
- 7 armchairs
- Built-in benches to seat a minimum of 25 persons

Referee's Office. This shall have a minimum area of 250 sq ft and adjoin and connect with the hearing room.

General Office with Public Space. This shall have a minimum area of 350 sq ft and connect with the referee's office and the chief clerk's office.

Chief Clerk's Office. This shall have a minimum area of 200 sq ft and adjoin and connect with the general office.

File Room. This shall have a minimum area of 250 sq ft and connect with the general office.

Trustees' Room. One or more rooms, approximately 250 sq ft, shall be provided for trustees in the larger courts.

Referee and One or Two Clerks This small suite shall contain the same rooms and equipment provided for referee, chief clerk, and two or three assistant clerks, except that the file room and chief clerk's office shall be omitted. Refer to Fig. 12.

Part-Time Referee and One Clerk In a district where there are very few bankruptcy cases to be heard, only one room may be required. When this one-room office is provided, the referee may hold hearings in a vacant hearing room elsewhere in the building or use his own office if only a few persons are to be accommodated. It shall have a minimum area of 300 sq ft.

Fig. 9 Probation officer with two assistants.

Fig. 10 Probation officer's suite (small installation).

Governmental and Public

COURTHOUSES

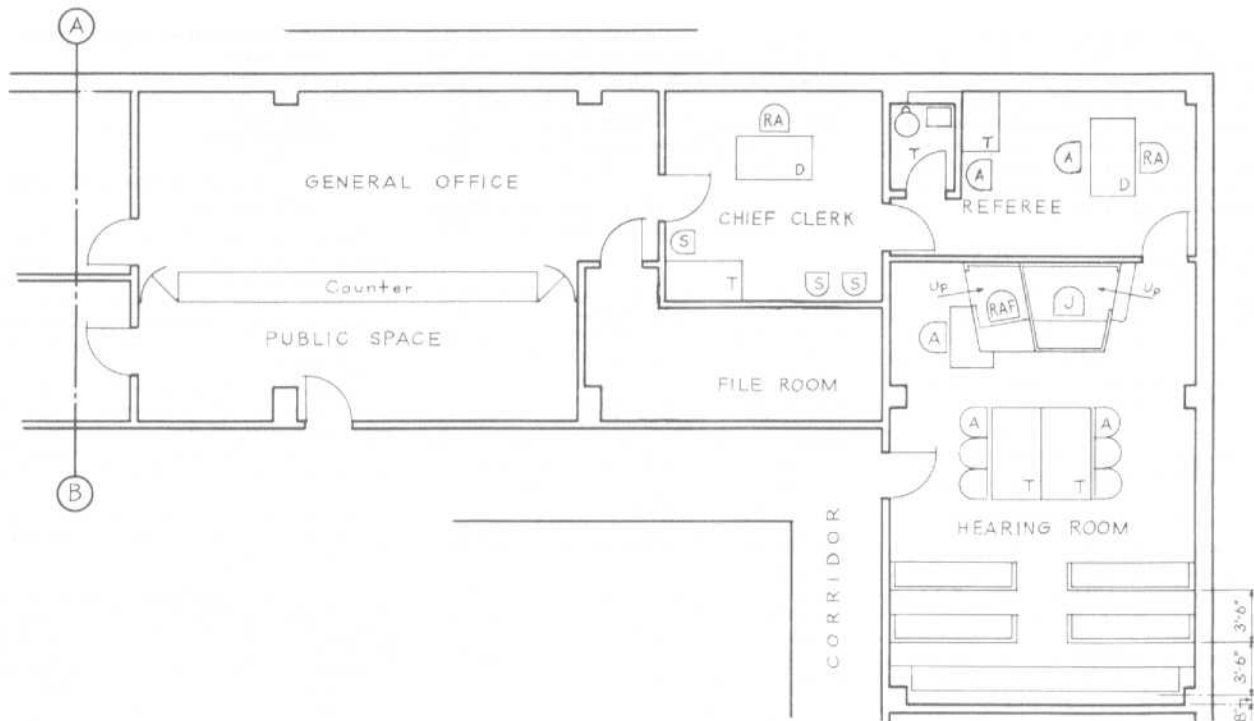

Fig. 11 Referee in bankruptcy.

Fig. 12 Referee in bankruptcy's suite (small installation).

Part 15. Miscellaneous Assignments

Quarters for Visiting Judges When these are required, the spaces shall be generally similar to those provided for the resident judge.

Court Reporter

Duties and Location. The court reporter makes the official verbatim record of the court proceedings and furnishes transcripts when required. His office may be located anywhere in the building. Refer to Fig. 13.

Components and Furniture. The reporter's quarters will include a general office, with file space, having a minimum area of 200 sq ft if the building has one courtroom. For each additional courtroom, add 50 sq ft to the general office.

District Court Library

General. When there are two or more courtrooms, a general law library may be required, convenient to the judges' chambers.

Arrangement. Reading tables should be located in front of windows. When window spacing will permit, put tables in small alcoves formed by bookstacks as separating partitions. Provide a main aisle at least 4 ft in width extending the full length of the room and separating the reading section from the general stack section.

Areas and Furniture. The size of the library will accommodate readers to be seated.

Bookstacks. Legal volumes average 2 to 2½ in. in thickness, 6 to 10 in. in width, and 8 to 11 in. in height. Thus a stack section 3 ft long and 7 ft 3 in. high with shelves 12 in. on centers will store about 98 legal volumes. Stack sections are made up on single-faced wall sections and double-faced freestanding sections, which must be arranged in rows with the range isles, 2 ft 6 in. wide, and accessible from the main aisle.

Fig. 13 Court reporters' offices.

Reading Tables. Each of these seats four people.

Press Room The location may be at any place in the building. Telephone booths with coin telephones will be installed. This room for news reporters may be required in buildings with two or more courtrooms. The minimum area of the room shall be 200 sq. ft.

CIRCUIT COURT OF APPEALS

Part 1. Description

Jurisdiction The circuit court of appeals and the Court of Appeals for the District of Columbia are the intermediate federal appellate courts, each having the power to review the decisions of the district courts within its judicial circuit and the orders and decisions of

certain federal boards, commissions, and other regulatory agencies. There are ten judicial circuits, each composed of several states. The District of Columbia is a separate jurisdiction. There may be several places of holding court within each judicial circuit, but each circuit court of appeals has a headquarters court within its circuit.

Spaces Required A courtroom with its auxiliary facilities, and spaces for each of the following will be required at each court:

Circuit judges (three or more)

Clerk of the court

Library

Marshal (only if court is in the District of Columbia)

Location The location of the circuit court within the building, and the relationship of its rooms, is determined by the same conditions that govern in the case of the district court. Refer to Figs. 14 and 15.

Part 2. Courtroom

Dimensions. The minimum size of the courtroom shall be 38½ ft in width by 50 ft in length; the ceiling height should be in proportion to the size of the room and be designed to meet the requirements of good illumination, ventilation or air conditioning, and acoustics.

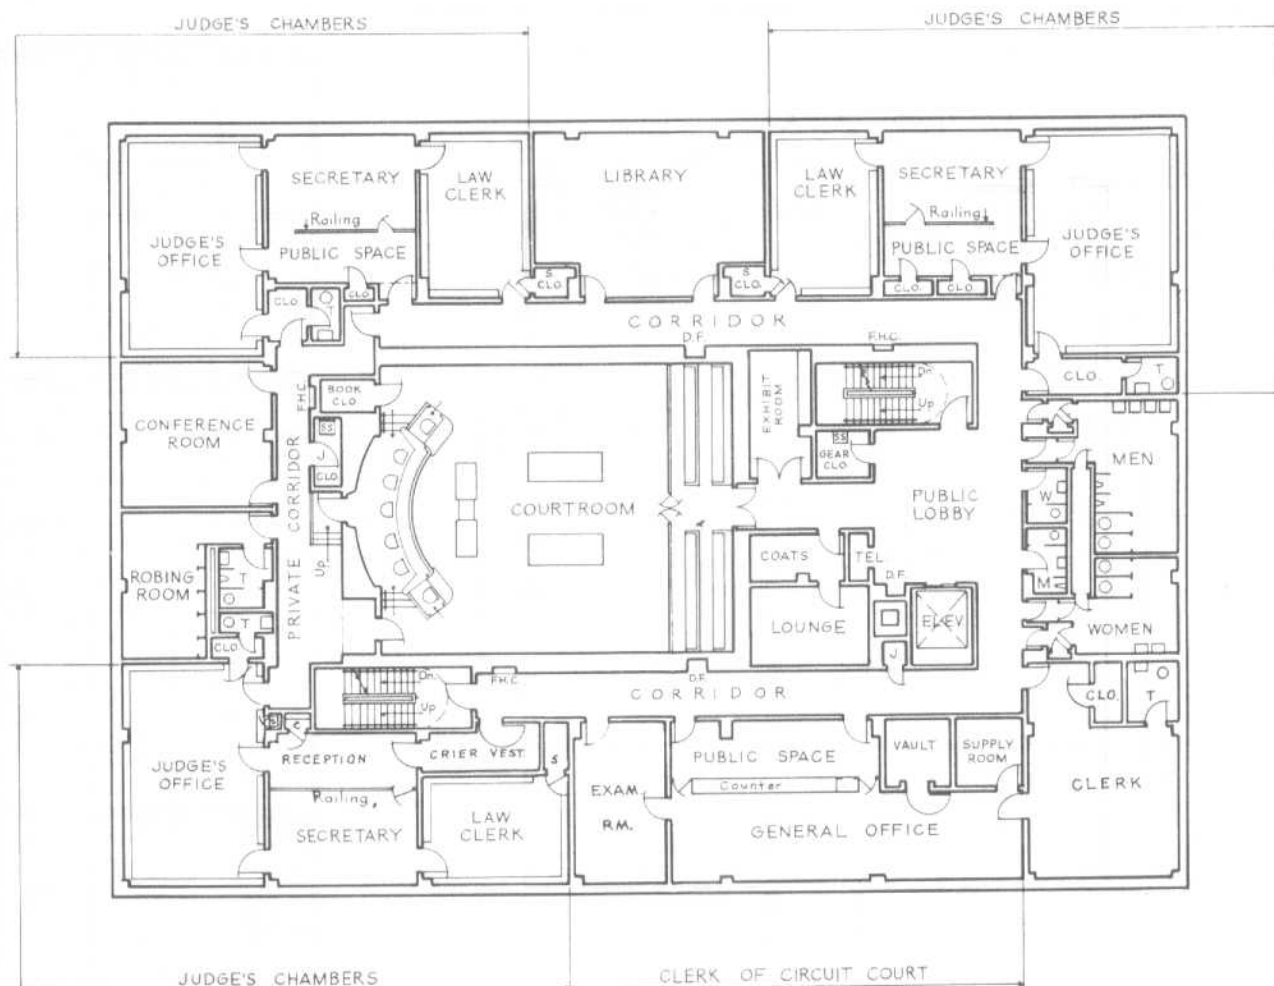

Fig. 14 Circuit court of appeals.

Governmental and Public

COURTHOUSES

Entrances The public entrance, the judge's entrance, and corridor entrances are indicated on Fig. 14.

Built-in Furniture It shall include:

Combination judge's bench, clerk's desk, and bailiff's desk
Railing and gates
Benches in public space to seat 32 persons at 2 ft o.c.

Movable Furniture This shall include:

- 5 judges' chairs
- 12 lounge chairs
- 1 pedestal armchair for clerk
- 1 pedestal armchair for bailiff
- 2 attorneys' tables, 60 by 34 in.
- 1 lectern
- 20 rotary armchairs for attorneys
- 2 attorneys' tables, 120 by 48 in.

Part 3. Judges' Suite

Location There will be three or more judges' suites for the circuit court of appeals. Each judge's suite shall be similar in size, arrangement, and equipment to the district judge's chambers except that more space for books may be required. The judges' suites need not adjoin the courtroom but shall be adjacent to it and preferably on the same floor.

Judges' Conference Room This shall have a minimum area of 400 sq ft, should be connected

to the judges' robing room and toilet, and must accommodate:

- 1 table, 120 by 48 in.
- 10 armchairs

Judges' Robing Room and Toilet Provide a robing room with a minimum floor area of 200 sq ft, so located that judges may enter the courtroom without passing through any public space. When the plan permits, the robing room may open directly into the courtroom. Provide a robe closet for each judge.

Part 4. Assignments

Clerk of Circuit Court—Large Installation This large suite shall be the same in location, size, arrangement, and equipment as that described for the clerk of the court except that there will be no naturalization clerk's office.

Library This shall be similar in location and size as shown on Fig. 14.

CUSTOMS COURT

Part 1. Description

Jurisdiction The United States Customs Court has exclusive jurisdiction over all civil actions arising under the regular tariff laws, the internal revenue laws relating to imported merchandise, and the provisions set forth in the various reciprocal trade agreements. Cases coming be-

fore the court for trial are handled under the legal procedure established by the Customs Administrative Act of June 10, 1890, and the several acts supplemental thereto. The court's function is to interpret the law and the facts respecting the classification of merchandise and the rates of duty imposed thereon. In addition to the court's exclusive authority to determine the dutiable value of imported merchandise, it also has sole jurisdiction in proceedings wherein relief is sought from so-called penalty or increased duties imposed by law because the final appraised value exceeded the value declared on entry.

Location

Headquarters. The United States Customs Court is in New York City. In addition to the regular trials during the year at New York, various circuits are held by the customs court in approximately 49 customs districts covering the entire United States and its possessions, embracing more than 298 ports or subports of entry. All its cases are tried without juries. In some forms of its litigation, the court consists of three judges, and in other cases the court is composed of only one judge. When cases are heard on circuit, the court usually consists of one judge or three judges. The judges on circuit are accompanied by a court reporter who also acts as calendar clerk. When the records have been transcribed by the court reporter, they are forwarded to New York and assigned to a judge or division for consideration and decision.

Fig. 15 Courtroom for circuit court of appeals.

Fig. 16 Customs court (field).

Field Quarters. The customs court field quarters, Fig. 16, are sometimes located in appraisers' stores buildings so that they are convenient to the customs examiners; but it is considered more desirable to have the courtrooms located in the federal courthouse, when practicable.

Ports of Entry. Facilities for customs courts should be provided at all ports of entry.

Space Required The field quarters suite is indicated in Fig. 16. It will include:

- Courtroom
- Judge's office (with toilet)
- United States customs attorney's office
- Attorneys' conference office

Part 2. Courtroom

Size The courtroom should have a minimum area of 820 sq ft. The entrance door should be at a point to the rear of the attorneys' tables to assure minimum disturbance by people entering or leaving during trials.

Built-in Furniture The standard built-in bench for three judges with witness stand and built-in benches to seat 40 persons are required.

Movable Furniture The movable furniture will be furnished and installed by the government. It includes

- 3 judges' chairs
- 1 witness' armchair, rotary and fixed-pedestal
- 2 attorneys' tables, 72 by 40 in.
- 12 armchairs

Part 3. Assignments

Judge's Office This shall have a minimum area of 500 sq ft.

United States Attorney's Office Provide a room with minimum area of 250 sq ft.

Attorneys' Conference Room Provide a room with minimum area of 250 sq ft.

By GEORGE H. TRYON and GORDON P. MCKINNON

FIRE DEPARTMENT STATIONS AND BUILDINGS

Fire department buildings include administrative offices; "stations," "houses," or "halls" housing the apparatus and equipment; fire alarm and communications centers; fire training facilities; and maintenance and supply facilities, including shops and storerooms. In some relatively small fire departments, all or several of these functions, insofar as provided, may be housed in one facility.

A. Administrative Offices

The administrative offices may be housed in a municipal office building or city hall, or at a headquarters or central fire station. Headquarters may include offices and facilities for the chief of department, the fire prevention division, the planning and research staff, the budget or fiscal bureau, the personnel department, the fire investigation bureau, and the medical officer. The exact facilities needed will vary with the organization of the individual department. It is desirable to arrange the headquarters offices so that the general public will not have to pass through the apparatus room or fire fighters' quarters to reach the offices.

B. Fire Stations

General There are two types of fire houses: one is operated by a paid fire department, the other by volunteers. Equipment for both is essentially the same. Differences occur in facilities provided for personnel.

Modern practice is to group companies and apparatus needed to protect a given neighborhood in order to provide better teamwork and administrative control. Most fire stations house at least one pumper company, with its assigned first line and reserve apparatus, and other companies, including aerial ladder, aerial platform, squad, rescue, salvage, and various auxiliary types of apparatus. Ample space is needed for reserve apparatus, both to provide a replacement when needed and as equipment for use by off-duty personnel recalled in an emergency.

Far too many fire stations have outgrown their usefulness because inadequate consideration was given to the future needs of the district. The cost of providing adequate apparatus storage space is relatively modest when compared with the total cost of a fire station facility. A desirable policy is to provide an apparatus room large enough to house at least six major fire department vehicles. Even where it is intended initially to house a single first line piece of apparatus, a prudent minimum would be a two-track station capable of housing two first line and two reserve or special-duty pieces. Space should also be provided for additional men, who will be needed when further apparatus is obtained.

Elements of fire house design are shown

in Fig. 1. All facilities indicated are desirable but not mandatory. In paid departments, one company generally consists of 14 men; in a volunteer department, quarters are provided for paid drivers only.

Apparatus Rooms It is preferable that the apparatus floor be unobstructed by columns. Future use of the space should not be circumscribed by having major rooms protrude into the apparatus storage area. For multitrack stations, a minimum width of 20 ft per track is recommended. This should be increased to at least 24-ft width for a single-track station. A suggested desirable unobstructed depth is 80 ft, with ceiling height of 13 ft (minimum).

Ample space is needed to permit work around the apparatus, changing of hose, putting on fire clothing when responding, and to permit free movement of personnel when answering alarms. Space is needed along walls for clothing racks, slop sinks, battery chargers, water tank fill connections, etc. Space should be provided for hose storage racks without obstructing access to apparatus. Table 1 gives sizes of apparatus.

Floor should be of concrete, designed to carry a load of 125 lb per sq ft.

Wall surfaces should be of an easily cleaned material, and floor should have sufficient drains to permit flushing with hose. Hot and cold water connections are needed at center of side walls.

If apparatus room is to be used for repairs, provide a repair pit. Also, carbon monoxide gases have to be exhausted to outside, usually by means of under-floor piping to which

motor exhaust may be connected with flexible tubing. (Recreation room on first floor should be raised at least 6 in. for protection against gas.)

Fire stations should have adequate office space and facilities for all officers on duty. This includes not only the various company officers but offices and quarters for district and deputy chiefs. Among the other facilities needed in fire stations are a watch room, a dormitory, a locker and washroom, storerooms, study rooms, a kitchen, recreation room, and hose drying facilities.

The watch room should be so located that the man on patrol can see the apparatus floor, observe all persons entering the building, and preferably see the street in front of the property. It should be the center of the station's fire alarm facilities and have facilities for turning on house lights and alerting and dispatching fire fighters. If a watch desk is to be used, it should be on platform raised 6 in. above apparatus room floor to allow man on duty to remain during cleaning. Floors of closets, toilets, oil room, stair landings, etc., should also be raised for same reason.

Volunteer fire departments frequently require other facilities at their stations including social halls or meeting rooms, recreation facilities, and ladies' club rooms or lounges, particularly where the volunteer fire company's quarters serve as a community center.

Apparatus Room Doors Doors for fire apparatus should be large enough to permit quick passage without accident. An opening at least 14 ft by 14 ft is recommended.

Table 1. Fire apparatus sizes

Note: Turning radius varies from 26 to 48 ft, according to type and make. "Cab-over-engine" type of apparatus is slightly shorter over all.

Village-Size Pumping Engine, 500 g.p.m.	
Length over all	24'-0"
Width over all	7'-6"
Height over all	6'-5"
Triple Combination Pumping Engine, 750 g.p.m. (most used)	
Length over all	28'-0"
Width over all	8'-0"
Height over all	6'-11"
Hook-and-Ladder Truck (removable hand-raised ladders)	
Length over all	41'-3"
Width over all	8'-0"
Height over all	7'-3"
Hook-and-Ladder Aerial Truck (4-wheel type)	
Length over all	58'-9"
Width over all	8'-0"
Height over all	8'-7"
Hook-and-Ladder Aerial Truck (tractor-drawn type, 6-wheel)	
Length over all	63'-6"
Width over all	8'-0"
Height over all	8'-7"
Clearance required	12'-0"

NOTE: THIS DIAGRAM DOES NOT INCLUDE PROVISION FOR SUCH ELEMENTS AS ALARM OR BATTERY ROOMS AND OTHER SPECIAL FACILITIES

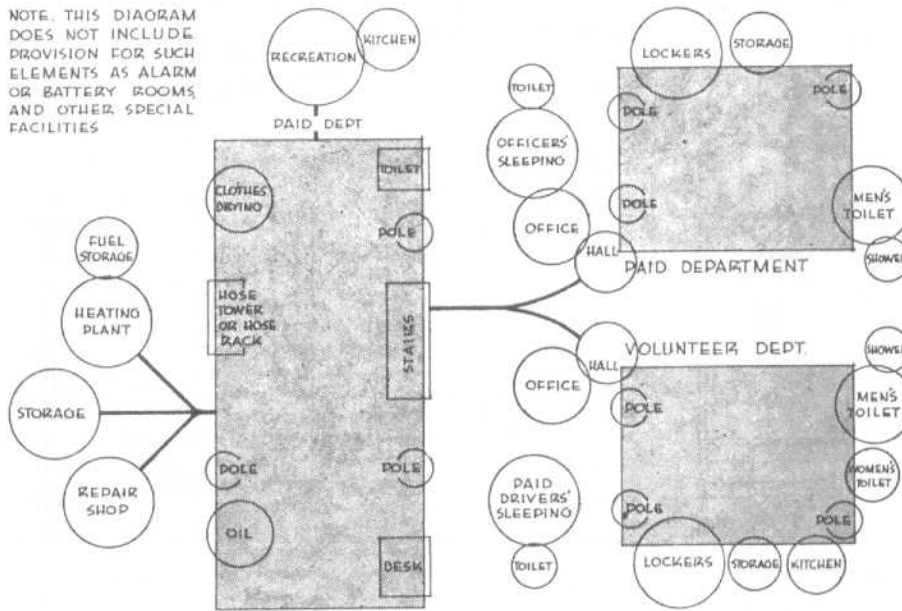

Fig. 1 Elements of a firehouse.

Designs for Stations Figure 2 shows suggested minimum space requirements for a district fire station intended for urban or suburban service where the station is to be mainly manned by full-paid personnel. The shape of the lot may vary with local circumstances, but it is considered very poor practice to start with a lot of inadequate size. A larger lot tends to have considerably more reuse or resale value at such time as it may be desired to add to the fire department facilities or to relocate the station.

The plan for an urban station shown in Fig. 4 provides space for two pumper companies (or a pumper company and a squad company) plus an aerial ladder or aerial platform company. Space is provided for reserve apparatus to be manned by off-shift personnel when needed. If desired, two-piece engine or truck companies can be operated out of such a station. Separate quarters with a garage are provided for the district fire chief so that he can come and go without opening up or lighting the main station and so that major apparatus can be taken out without moving the chief's car.

Unless required by the terrain or grade, a basement is not recommended under the main apparatus room as this tends to add materially to the cost. However, where the terrain makes a basement necessary, the main apparatus room may be reduced in size and a garage for reserve apparatus provided on the lower level. A basement may be desirable under the living quarters to provide room for heating equipment, storage, and other facilities.

The apparatus area should be of modern garage-type construction. It is good practice to provide automatic sprinklers for a fire department station. This has training value as well as providing fire protection for a type of garage occupancy which has a rather poor fire record. The heat for the garage area (where required) may be controlled by a separate thermostat from the company quarters. Where a hose drying tower is provided (see NFPA No. 198) it may also be equipped as a drill tower.

For a rural fire station manned chiefly by call or volunteer firemen (Fig. 5), space should be provided initially for not less than four pieces of major apparatus including a pumper, water tanker, booster pumper or forest fire truck, and a reserve pumper or second tanker. Often a rescue truck or ambulance also must be housed. Far too many rural fire departments have quickly outgrown their stations and have been forced to leave part of their apparatus outside or in a private garage where it is not readily available for use or under close fire department supervision.

Adequate meeting room space is needed, with proper exit facilities. The station should be located on a plot large enough to permit doubling the apparatus room when the department grows and to provide future office space

and quarters for paid apparatus drivers who may be subsequently employed.

It is bad practice to crowd three pieces of apparatus abreast in space designed for two trucks; this slows response and makes it difficult to properly service apparatus.

In Figs. 4 and 5 apparatus doors are shown at the front and rear of the stations. These are desirable so that the apparatus in the second line can leave the building in event of mechanical failure of a first-line piece. In some cases, where the lot has a long road frontage, it may be desirable to provide more apparatus doors facing the road and to reduce the depth of the building to about 50 ft. However, care should be taken to allow ample depth for major apparatus which may be purchased, such as large "nurse tankers" or apparatus with long ladders or an aerial platform. Normally, fire stations are expected to give 50 to 60 years of service, and what starts as a purely rural district fire station often has major properties to protect as business and industry move into the area. This may require facilities to house additional major apparatus and manpower.

Parking Facilities Parking areas for firemen's cars should not be overlooked. The station should have a parking area large enough to provide off-street parking for each fireman on duty or scheduled to respond to fires. Where call or volunteer firemen are to respond to the station to man apparatus, ample parking space should be provided adjacent to the front of the station. With paid departments, parking should be at the sides or rear. Additional yard space should be provided for company drill work. Figures 2 and 3 show plot plans for urban and rural stations respectively.

The apron or ramp in front of the station should be large enough to permit washing of apparatus and safe entry of vehicles into traffic.

C. Fire Alarm and Communications Buildings

The communications building or fire alarm office should be of fire-resistive construction and isolated from all hazards that might interfere with the prompt transmission of alarms. Where the fire alarm office is part of a fire station or administration building, it should be

Fig. 2 Plot plan for a typical district fire station for urban and suburban services. Minimum recommended plot size is 43,200 sq ft.

Fig. 3 Plot plan for a typical rural fire station. Minimum recommended plot size is 43,200 sq ft.

Governmental and Public

FIRE STATIONS

isolated from the rest of the structure and protected against all hazards both internal and external. Ample emergency power should be provided so that the station and communications equipment can continue to operate should outside power fail.

The communications office includes the operating room where all alarms are received and transmitted to the department. It also should have the telephone switchboard for the department, the radio control console, voice amplification controls, fire alarm circuit panels, and test equipment. Frequently, a central console is provided containing all communications controls and information needed by the dispatchers. There should be an office for the fire alarm superintendent, drafting room for plans, battery room, storerooms for fire alarm supplies, garage for fire alarm vehicles, and facilities for fire alarm personnel.

D. Fire Training Facilities

Facilities needed for the fire department training program include study rooms and library facilities in each fire station. A fire training center should include adequate classrooms and training aids. The better training centers have an apparatus room where major apparatus can be brought indoors for instruction purposes, and the operation of various items of fire protection equipment (hydrants, fire alarm, and automatic sprinklers) can be demonstrated. Other desirable features include an auditorium where various fire protection conferences and training meetings can be held, facilities for preparation and reproduction of training manuals and bulletins, and a fire protection library.

Outdoor training facilities should include large grounds with various structures for demonstrations and practice fires, a drill tower for hose and ladder evolutions, tanks for practice on flammable liquids fires, electrical and gas utility installations for fire training purposes, hydrants and pumper suction facilities, and other equipment duplicating situations that may be encountered at fires. When an individual fire department is too small to provide all the necessary training facilities, the practice is to supplement the local training program by use of regional or state fire schools which do provide more adequate facilities and curricula. The NFPA book, *Firemen's Training Centers*, gives additional suggestions for planning such facilities and contains illustrations of some typical centers.

E. Maintenance Facilities and Shops

Facilities for maintenance and repair work on fire apparatus should be provided. A repair shop includes an area where major apparatus, including ladder trucks, can be serviced and repaired.

By EMMANUEL MESAGNA, R.A.

FIREHOUSE PLANNING

Over the past decade, Firehouse Planning and Design has become increasingly sophisticated and complex. Years of study and experience have made it apparent that by planning a firehouse properly, a safer and quicker turnout can be made. This is accomplished primarily by arranging traffic flow patterns within the firehouse to be as direct as possible. The integration of the "primary adjacency" concept for planning the firehouse will deduct considerably from the turnout time by "grouping" the firefighting personnel in the "highest activity" areas of the firehouse. Turnout time along with dispatching time and travel time are three of the key elements in the successful containment of fire which is one of the primary goals of a firefighting unit.

The improvements in firehouse planning have created a total upgrading of human comforts with great emphasis on physical fitness. These include well-planned kitchens, air conditioning, better lighting, well-planned toilet-shower facilities and dormitory spaces, acoustical improvements, safety features in building planning and the integration of a small gymnasium-like area, for physical fitness purposes in firefighting needs, into the firehouse plan.

Concept Planning for the Firehouse and Plan Types

Turnout time is the key element in firehouse planning. When planning the firehouse the most important feature is to group various functional spaces in a primary adjacency pattern so that movements to exit from the firehouse are minimized. Dispatching, travel, and turnout time are the key elements in the successful containment of the fire.

The one-story firehouse has a series of plan types which can be categorized in the following manner (see Fig. 1):

(A) One-Way Straddle of the Apparatus Area
All of the support functions for this plan type are located to the left or right of the apparatus area. This plan type is the least desirable in that the plan has the longest travel distances to reach the apparatus area and therefore adds to the turnout time of the fire company. This plan type by its nature creates a circulation pattern which can be eliminated in other plan types. Other plan types have supporting areas responding directly onto the apparatus area.

(B) Two-Way, U Wraparound of Apparatus Area
This plan type is the most desirable for purposes of minimizing the turnout time in firehouse planning. Using the same gross area for the standard two-company unit, it places all areas at the shortest possible distance from the responding apparatus. Another key element in this type of planning concept is that it separates the noisy areas of the firehouse from the quiet areas by the natural separation of the apparatus area.

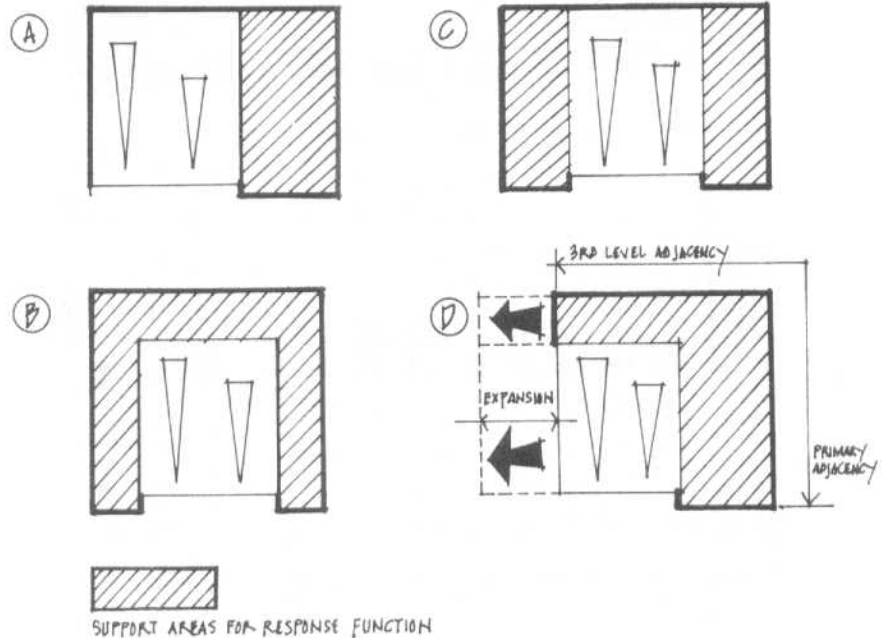

Fig. 1.

(C) Two-Way Straddle of the Apparatus Area
This plan type is the second most desirable for purposes of minimizing the turnout time in firehouse planning. The plan clearly separates the noisy areas of the firehouse from the quiet areas and may create circulation patterns in the support areas by not taking advantage of the back of the firehouse for support area use. This plan type is the same for the two-story firehouse with the quiet volume stacked over the apparatus area (see Figs. 2 and 3).

(D) L Wraparound of the Apparatus Area
This plan type is unique in that the location of the L arrangement allows for the natural progression in locating the primary adjacency areas through the third-level adjacency areas as the L wraps around the apparatus area from the leg of the L to the toe. The key turnout spaces are placed in normal sequence by virtue of its form. One of the advantages of this plan type is the flexibility for expansion along the apparatus area and the toe of the L. This plan type is the third most desirable with the advantage of potential for expansion.

Adjacency Relationships for Space Planning of a Firehouse

The key concept in planning a firehouse for the shortest turnout time possible is the development of an adjacency planning concept. The main purpose of this concept is an in-depth study of spaces in a firehouse which require an "adjacency rating" for purposes of functional planning of the firehouse to verify where the greatest amounts

of activity occur. These "activity locations" will then be joined in such a manner that a minimum amount of grouping time is required for the firefighting personnel to respond to the fire. This grouping time is extremely valuable to the response action. At this time the company officers develop a response strategy for the shortest route to the fire location and the problems of the fire condition.

Primary Adjacency Spaces in this category must be directly connected in a physical manner to each other or directly to the apparatus area which is the key turnout location in the response action.

Secondary Adjacency Spaces in this category must be placed at a midway location in the firehouse plan because of the dependency of function during day-to-day operations that are not of primary importance.

Third-Level Adjacency Spaces in this category are the least used in a firehouse and have no direct day-to-day operational relationship to the primary and secondary adjacency spaces.

Primary Adjacency Spaces

- Dispatcher-housewatch area, lobby area
- Administrative—company offices
- Kitchen/recreation area/gym area/training area
- Lounge area
- Classroom facility with accommodations for television, videotape teaching
- Basic toilet area (close to high-use areas)
- Dormitory areas

FIREHOUSES

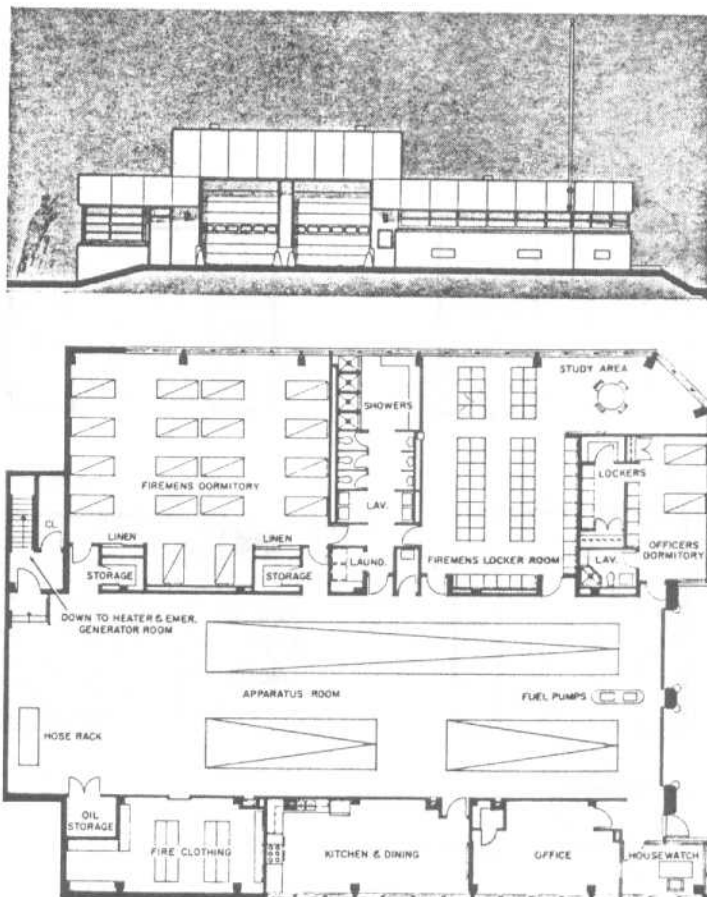

Fig. 2 Typical plan and elevation of a one-story firehouse. Front elevation and floor plan of one-story firehouse which features "active" and "quiet" sections of the firehouse divided by the apparatus floor, a good example of the two-way straddle of the apparatus area.

Turnout gear storage (can be third-level adjacency according to response action strategy)

Secondary Adjacency Spaces

General shop, storage, repair area
Cleanup areas
Hose storage/drying area

Third-Level Adjacency Spaces

Apparatus parts storage
Boiler plant, utilities, and emergency generator area
Locker room area
Miscellaneous storage areas
Major toilet-shower area, clothes washing and drying area
Administrative area—not related to the response action
Conference/public areas
Any other function not directly related to the response action

Note: Adjacency levels must be ascertained through in-depth interviews with fire department administrators and may change accordingly.

Space-Planning Analysis to obtain the Gross Area Requirements for the Firehouse

Prior to site selection it is essential that an architect/space-planning analyst be retained for purposes

of ascertaining the gross area requirements for the firehouse. A space-planning analyst is a new breed of expert whose main responsibility is to arrive at the most efficient total gross space required for the building. High building costs have necessitated the use of a space-planning analyst to obtain the *least* gross area for the building function with maximum efficiency.

The space-planning analyst will make in-depth studies of equipment, personnel, utility needs, and circulation and arrive at the optimum gross area requirements for the building. Prior to planning a firehouse, it is essential that all equipment and personnel needs are clearly delineated in numbers and size so that proper circulation allowances can be made for the proper functioning of the firehouse; these in turn will give the gross area requirements. As part of the study by the space-planning analyst many options will be offered which will examine the level of *maximizing* or *minimizing* the space needs and the ultimate advantage and disadvantage of each as they relate to the function of the building.

Building and Site relationship

Three of the major considerations related to the building and site relationship are the building setback, training area requirements, and the onsite parking requirement for firefighting personnel. The minimum setback is 30 ft and should ideally be standard at 65 ft to accommodate the largest

piece of apparatus in the fire service. This will give optimum visibility for apparatus exiting from the firehouse. The apron area shall have the smallest possible slope to drain water and may include a hot-water underground piping system or electrical cable de-icing system to clear the apron for response purposes. All building sites require an open area to one side of the firehouse for purposes of training with the largest piece of apparatus available to the firefighting unit. A parking area to accommodate all personnel on duty at any one time is absolutely necessary, plus a minimum of 50 percent more as extra space for administrative personnel. Beyond this point the parking requirement is a subjective judgment which may include parking spaces for public and social functions. The parking area is to be located adjacent to the dispatcher-housewatch area with visual control of the activity in the parking area.

The main arterial street shall be wide enough to accommodate the apparatus with the largest turning radius. It is also essential that traffic controls be installed on extreme ends of the front property line to stop traffic during a response action.

As a secondary consideration, any responding of apparatus directly into the low sun orientations shall be eliminated to do away with the vision problem of the quick transition from basic darkness to brightness and the ensuing accident potential, by orienting the building properly.

Wherever possible additional land should be allocated to the site footage for purposes of integrating the drive-through apparatus area arrangement in the floor plan. This method of returning from the response action creates less disruption in the street and potential for accident during the backing up of apparatus.

DISCUSSION OF THE VARIOUS SPACE COMPONENTS IN FIREHOUSE PLANNING

Dispatcher-Housewatch Area

This key communication area is being formed as an independent operating space, completely sound-controlled for optimum hearing ability. It must be completely air-conditioned and have maximum visual control of the quarters and street conditions. Glass areas in the front of the housewatch are arranged in such a manner, that 180° of visibility in front of the firehouse is possible. The alarm lights button at the fire communications console is not limited to activating the alarm lights as in the past. The alarm button also activates the apparatus fume-exhaust system and a series of floodlights mounted on the front face of the building. These lights illuminate the apron area and street for a safer response. An adjustable timer turns off the floodlights and the fume-exhaust system after the overhead doors have been electrically secured shut. They can be activated manually through an override switch by the housewatchman in other than response situations.

Control Functions of the Dispatcher-Housewatch Area This key communication area is also the center of all electronic switching devices which control the security and functioning of the firehouse and include:

1. Gasoline and diesel pump operation
2. Manual operation of floodlights mounted on the front of the building
3. Security lights surrounding the problem areas of the building
4. Manual control of fume-exhaust system
5. Alarm lights for various parts of the building during response action

First-floor plan of the two-story firehouse.

Front elevation of the firehouse.

Second-story plan of the two-story firehouse.

Fig. 3 Typical plans and elevation of a two-story firehouse, a good example of a two-way straddle of the apparatus area with the "quiet" section stacked over the apparatus area.

6. Daily-use light control

7. Control of overhead doors with up and stop buttons only for safety purposes; down button located at overhead door location only

8. A complete intercom system for immediate verbal communication to all areas of the firehouse plan

Management Adjacency The planned adjacency of the housewatch and the company offices affords excellent audible communication between the dispatcher-housewatch area and the company offices—the management arm of the firehouse. Both areas also face the apparatus storage area and have glass walls, allowing for visual control of the apparatus floor. This adjacency of space is ideal for all aspects of communication and decision making during initial turnout action.

The Apparatus Storage Area

This is the heart of every firehouse; its location, shape, flexibility, size, layout, and column-free approach will provide for easy, quick access from all areas in the four major concepts in planning a firehouse. These factors will provide the fire-fighting units with a good functional design for response purposes. The integration of the large areas such as the apparatus area and hose storage area into one large, open apparatus area and the elimination of the turnout gear storage from the apparatus area have allowed for "clear space" mobility. The single open space now offers greater flexibility in the apparatus storage area and may also function as an area for training and for storage of spare or down apparatus.

Apparatus storage areas are now being equipped with a sophisticated fume-exhaust sys-

tem. The fume-exhaust system is activated from the alarm lights button located on the fire communications console unit. The fume-exhaust system is capable of a massive exhaust pull of 5000 cfm which is the equivalent of six changes of air per hour. A timer will automatically shut the system down after a set time lapse. Provisions have been made for the manual control of the fume-exhaust system when companies are not in a response action. A study of fume-exhaust pipe locations on the apparatus has allowed us to place intake grilles at optimum locations for greatest intake pull. Our goal is for the maximum elimination of fume-exhaust gases on the apparatus floor. Upon the return of the apparatus to quarters, a manual switch operation can be utilized and the fumes can be exhausted as long as required for the comfort of the personnel.

It is recommended that all apparatus areas

FIREHOUSES

utilize single apparatus doors approximately 12 ft wide by 14 ft high. Wide, single-opening apparatus doors are not recommended because of the possibility of having the door frozen closed due to a breakdown in the mechanized door operation. This situation will put the responding apparatus out of service and increase the response time of first-due apparatus. A pair of doors is more functional in that a breakdown in one door will allow the responding apparatus to maneuver through the other door. This will eliminate the turnout problem in case of an emergency breakdown of one of the mechanized overhead doors. It is essential to include a totalizer on all apparatus doors so that tension springs may be replaced on a preventive maintenance schedule based on predictive breakdown of the equipment. This standardization of door-opening size will simplify the storage of spare parts for repair purposes. All door operators, springs, track, turning shafts, and other accessory equipment of a single size will simplify the storage of parts while minimizing the inventory burden. It is recommended that all overhead doors be opened with electrical operators for purposes of decreasing the turnout time. Electrical operators shall have the capability of manual operation in case of breakdown of the motorized equipment. It is essential that the overhead-door-operating equipment be put on the emergency generator in case of electrical failure in the community.

Generally throughout the fire service, the hose tower is being eliminated as a functional need in the operation of a firehouse. With the use of sophisticated hose drying equipment and the use of polyester hose which does not require drying, the hose tower is being phased out in both new and existing firehouses.

Turnout Gear Storage

A well-planned firehouse shall have facilities for storing helmets, coats, and boots with accommodation for washing and drying out, as well as a floor drain system. The turnout gear storage area shall be secured with a pull-down see-through mesh gate arrangement and locking device to secure the area while the company is out of quarters. Included as part of the equipment for this area shall be an electric heater for drying and an exhaust fan to clear out the humidity in the area. The wall and ceiling finishes in this area are critical for maintenance and shall include maintenance-free finishes such as permanently glazed surfaces.

Slide Pole and Enclosures

There is a movement in the fire service to generally eliminate the slide pole as a means of circulation from the second floor of a firehouse. Serious injuries have occurred in the use of slide poles. Their use is generally discouraged in favor of a stairway or the trend toward the one-story firehouse, wherever the land value permits, in all areas of the country. In some areas of the country, particularly in the urban areas, the air rights over firehouses have been sold to developers to offset the high land cost.

Classroom-TV Amphitheater for Training Purposes

The future of all training programs will be in the firehouse through the medium of closed-circuit television and videotape. For this purpose a sophisticated space is required in order to create a positive environment for learning. The space will

require complete acoustical treatment, theater-type viewing chairs, a sloped floor arrangement for viewing purposes, and a desk top writing surface. In terms of adjacency level, this space is classified as a primary adjacency and shall have direct access to the firefighting apparatus area.

Kitchen-Dining Room-Recreation Area

The kitchen-dining room area is completely planned for reduction of maintenance and efficiency of operation. Each component shall be planned for the level of commercial use completely in stain-

less steel. Included also are a large refrigerator and a six-burner range (commercial type) with a grill unit and oven. This is a heavy-duty commercial range with a proven successful performance. Included is a stainless steel range hood with removable and washable stainless steel filters. The ceilings are of washable acoustical tile and the floor and wall are finished in a ceramic or quarry tile, which has eliminated maintenance except for simple cleaning.

Dormitory-Locker Room

New planning concepts have the dormitory and locker-room spaces straddling the toilet-shower

and clothes-washing core areas. This provides sound isolation between the noisy locker room and quiet dormitory area. In cases where the dormitory area faces onto a traffic street it is best not to provide any windows on the dormitory walls facing the street. This type of planning will give maximum sound isolation and privacy for this quiet area of the firehouse.

Chief's Quarters

A refinement of the planning of the chief's quarters has produced a unique privacy aspect and efficiency of response. The chief's car and his turnout gear storage closet are located at the

base of the egress stair or circulation corridor at the apparatus floor level, with his office and dormitory having direct access to his response vehicle. In the typical two-story firehouse illustrated (Fig. 3), the chief's quarters are located at the head of the stair at the second floor and he goes directly into his suite of rooms from the egress stair. This eliminates many unnecessary steps by giving the responding chief direct access to his response vehicle. This will eliminate circulation patterns which in the past carried the responding chief through the company locker room and dormitory. There is a continuity of function between the chief's car area, the chief's turnout gear storage, the egress stair, and the responding chief's office and dormitory; the adjacency of these spaces indicates a minimum circulation pattern.

DISCUSSION OF THE ADVANTAGES OF THE ONE-STORY FIREHOUSE OVER THE TWO-STORY FIREHOUSE

There is a national movement generally to eliminate the two-story firehouse as a planning concept in firehouse design.

The arguments in favor of the one-story firehouse are mainly based on positive facts and response action strategy:

1. Injuries to members of the responding fire companies resulting from the use of stairs and slide poles will be eliminated.

2. Elimination of the physical exertion required in the constant up and down activity of a high-activity firefighting unit.

3. It is apparent that the most economical solution to firehouse design is the one-story firehouse. It is approximately 10 percent lower in cost than the two-story firehouse and becomes a trade-off when evaluating low land cost and the difference in construction cost between the one-story firehouse and the two-story firehouse. Although the one-time land costs have been made an obstacle to the one-story firehouse, the determining factors in the decision for a one-story or two-story firehouse shall be the efficiency of response and the reduction of maintenance and operational burdens which are life/cycle determinants. This maintenance and operation burden will far exceed the original cost of the land.

4. As a secondary option for high land cost, the value of the land can always be recouped by selling the air rights over the property for future development or for additional floor area to adjacent parcels as allowed by the zoning regulations in the particular municipality.

POLICE STATIONS

HOUSING

Perhaps no item of police equipment or property has the potential for providing or denying optimal utilization of command and supportive services personnel in any greater degree than the police headquarters building itself. Earlier this century the automobile reduced the need for large numbers of officers to provide on-street police service or for emergency standby purposes, but no such dramatic invention has reduced the nonline personnel requirements of a police agency. Indeed, the complexities of staff and auxiliary services and the utilization of sophisticated automated data processing equipment and systems, the growth of planning and research activities, the increase in training requirements—all emphasize the need for sound planning of police facilities if both space and personnel are to be used effectively and economically.

When an old building is recognized as inadequate several alternative responses to the problem may be identified: (1) doing nothing about the building or its floor plan and employing additional personnel in numbers sufficient to overcome the operational handicaps of the existing facility, (2) reducing service to the public and to the line or field elements of the department whenever the physical and functional relationships of people and their work are such that they require more time and/or personnel than is presently available, (3) researching the departmental and public needs and redesigning and modifying those portions of the structure which present operational or administrative problems, or (4) designing and constructing a new facility.¹

In some situations, the handicap of a poorly arranged building may be overcome by minimal reconstruction or relocation of offices and work areas, though this approach may not always be used to great advantage in cases where unusual problems exist. It is generally unwise, however, to attempt to redesign the police station in an existing structure. Experience throughout the nation has shown that such moves may eventually cost more than new construction, and the results are seldom satisfactory. The most economical approach, if viewed from a 20- to 40-year vantage point, probably will be in the design and construction of a new facility. This is true because the expenses of reconstruction are essentially a one-time cost, but the personnel costs of employees whose work performance is limited or wasted through poor building design continue year after year. Moreover, delaying new buildings when the need is apparent can be costly because of rising construction costs.

If only one unnecessary 24-hour per day posi-

¹ Whenever a new building or a major restructuring of an old one is under consideration, the key decision to be made does not concern building design at all—it is analysis and appraisal of departmental program and organization. All too often a building is designed to fit an antiquated, unrealistic agency structure. Thus a review of department organization should be made, accompanied by necessary changes, before a new building design or modification of an old one is attempted.

Municipal Police Administration, 1971, International City Management Association, Washington, D.C.

tion is saved or eliminated by such a move, the annual salary savings amounts to approximately five times the cost of one person's salary and fringe benefits. Unnecessary recurring personnel expenditures are a major consideration in building design. The luxury of poor working quarters is beyond the reach of most police departments in the United States. Given an already undermanned field force, the additional cost burden for personal services occasioned by poor building design is a major consideration. Fortunately, there is a developing awareness of the impact of poor design on police efficiency and costs for personal services.²

DESIGN OF A POLICE BUILDING

In designing modifications of an existing structure, or when plans are drawn for a new police facility, many factors should be considered. These involve functional relationships, economy of space, public convenience, security, etc.

Functional Relationships Offices and work areas of elements performing essentially the same tasks should be grouped so as to achieve maximum use of physical facilities, thereby avoiding duplication of equipment or furnishings. For example, the work of records and communication units are so interrelated and mutually supportive that space arrangements should assure direct access from one to the other. Further, temporary reassignments of personnel could easily be made between the integrated elements as work loads vary between the two. Administrative line officers should be grouped closely. Booking, identification, and detention operations must be so related that time and travel distance are shortened to conserve personnel resources and to avoid security problems.

Public Considerations Public access should not conflict with prisoner passageways or areas; this will avoid exposure of prisoners to the public and will eliminate the possibility of harm to either. The public, of course, must be restricted in its movement within designated areas of the building. Avoidance of prisoners' public contact eliminates the possibility of embarrassment, particularly to women and children, and criticism of the agency and its procedures. Also eliminated is the possibility of passing weapons to prisoners and escape efforts.

Public counters or business windows should be within reasonable distance of the building entrance to avoid public confusion and to limit the public's need to move about the police buildings. The public information and complaint desk should be adjacent to the communications or dispatch area. This is particularly important in the smaller departments. Equally important is provision of a single complaint counter or center; this avoids

² Under modern conditions of employment—the 40-hour week, generous vacation and holiday leave, and in-service training, for example—about five persons, give or take small percentage differences, are required to man one fulltime post 24 hours per day throughout the year.

duplication of services or permits better administrative control and convenience. Public telephones for the use of attorneys, bondsmen, visitors, and the public should be located away from the main counter to avoid confusion and disruption of ongoing police services.

General Design Considerations Building design should make possible the use of only one floor, or a section of one floor, during those hours when the administrative offices are closed. This concept has full applicability to both small and large agencies. Such design tends to keep operating costs low and improve general security. Whenever possible, walls for offices, rooms, and assembly areas should be of modular construction which permits expansion and flexibility of operation. Metal and glass partitions, and even file cabinet dividers should be used for functional allocation of space whenever privacy is not a major consideration; open space should predominate. Lighting, decor, and acoustical treatment should be planned carefully to increase comfort and efficiency of personnel.

Adequate parking facilities should be provided, including space for vehicles belonging to all agencies using the building, on-duty personnel, and clients and visitors, plus reasonable space for emergency needs. A distinction should be made between official and public needs. Location of parking space should provide for close access to the building by kinds of use.

Communications, Records, and Evidence The communications operation, including radio consoles, monitoring units, teletype machines, alarm systems, and telephones, should be housed in an air-conditioned, acoustically treated room. Teletype machines may require separate and acoustically treated cubicles to minimize the effect of their noise. The room should be designed to assure privacy and security; only police personnel on duty in communications and records and certain other authorized personnel should have access to it. In addition, the communications center should be on a raised, paneled floor to allow for adequate conduits and wiring and to provide flexibility when rearrangement is necessary.

Design of the records facility should provide for utilization of under-the-counter files in appropriate locations. In addition, vertical shelf files should be used whenever practicable to reduce storage space; closed shelf files provide all the features of standard file cabinets but require less room. As suggested earlier, file cabinets of five or more drawers can be used effectively as space dividers which provide for a measure of privacy. Acoustical treatment, false floors, and air conditioning are essential in the design of space for electronic data processing equipment. Duplicating and printing machines which create noise problems should be housed in acoustically treated cabinets within the services area.

Automatic multtape typewriters should also be located in a separate, acoustically treated room rather than in the general office area. Provision for the safekeeping of evidence and recovered property should be made within the services of-

POLICE STATIONS

offices and should be separate from those facilities used for prisoners' property.

Detention and Related Facilities All prisoner facilities should be located near the services element to enable personnel to perform booking and turn-key duties whenever possible, thus minimizing the need for jailkeeping staff. Provisions should be established whereby prisoners may be held in separate security areas prior to being booked. This will prevent prisoners not yet booked from disposing of possible evidence in their possession or from passing dangerous weapons through cells to prisoners already in custody.

The outside entrance to the jail and detention facilities should open to a drive-in garage. Police vehicles should be able to drive into the interior of the police building, with the outer garage door opened and closed remotely from within the area, and still remain outside the main detention and booking area. A second door which separates the unloading area from passage to the jail, also electrically controlled from within, should be provided. Means of providing security for the transportation of prisoners or material witnesses to court from the detention areas should be planned carefully, and conflicts with routes of nonpolice traffic within the building avoided.

Visitors' and attorneys' rooms must maintain all but audible and visual separation between prisoner and visitor.

A separate, secure storage area for prisoners' personal property should be provided within the booking area, preferably under a counter. It should contain enough cubicles to allow each to be numbered to correspond to the cells and bunks within each cell. For example, the first compartment logically would be 1-A, meaning Cell Number 1, Bunk A. It would contain property only if a prisoner were occupying that cell and bunk. This procedure would permit booking or detention personnel to immediately return property to a prisoner as he is released, avoiding unfortunate loss or destruction of property which has been mislaid or forgotten at the time of his release.

Closed-circuit television may be installed at various vantage points within the security areas for protection of police and detention personnel and for observation of prisoners, if direct observation of prisoners cannot be accomplished because of jail location or design without additional station personnel. A special portable extension telephone should be provided for prisoner use and located in a secure and private area within the detention facility. A gun reception and storage area should also be provided near the jail entrance where police officers may turn in their weapons to the officer in charge before entering the detention areas.

Provisions for Multiple Use Often classrooms, assembly, and other rooms may be designed to form a complex of interrelated multipurpose areas, giving sufficient flexibility to allow use for roll call, training classes, police community relations meetings, public hearings, scout troop meetings, and other purposes. A little foresight in the design of this section of the building can save a considerable amount of wasted space which is used only sporadically. Coupled with careful planning of class or meeting schedules, the same space can often be used for almost the entire day.

Service Facilities

It is important to the progressive police administrator that staffing requirements of the depart-

ment's administrative and service elements be kept at the lowest level, consistent with continued high-quality service to other elements within the department and to the public. This is possible only when the design and physical layout of the police facility are responsive to this need.

Important in the design of any building is the location of the records and identification files and the communications center. These are intimately related in function and purpose. If possible, the communications center and the records office should be located back-to-back, with facilities provided to allow for the direct exchange of information during those hours when clerks are on duty in the records office. In those departments where records clerks normally are not on duty around the clock, direct access to current records must be provided for the communications personnel; otherwise the lack of immediate availability of previously gathered information will handicap field forces.

The property room should also be located in or near the records center and close to the public information counter or desk. The communications center should be a room of sufficient size to provide an adequate number of dispatchers' positions, status boards, a supervisor's monitoring and backup position (perhaps only a desk initially, later to be replaced by a complete radio console), and teletype transceiver units. The records staff should be trained so that its personnel can provide additional manpower in the communications center during periods of maximum dispatching need. Unless appropriate physical facilities are provided to allow mutual assistance, additional personnel must be assigned to the communications section to allow it to handle overloads as well.

The auxiliary services work area should be air conditioned to provide optimum comfort for personnel and citizens conducting business there. Provisions for rest rooms, filing cabinets, and space for additional personnel during peak work periods should be provided near the communications center. It is axiomatic that the greater the distance to these areas, the greater the manpower cost to the department.

Administrative and Investigative Offices

The location of offices for the chief of police, division command offices, and the working offices and areas for criminal investigators, vice officers, youth officers, and administrative and staff support personnel, while not perhaps as critical as that of the records and communications center, has far-reaching operational and public relations implications.

Depending upon the size of the department, the chief of police and top-level command officers should have some freedom of movement and privacy. Some chiefs find it nearly impossible to function effectively while in their offices because of constant interruption by visitors who should normally be assisted by desk officers or other personnel. Frequently a visitor will demand to see the chief, rather than the proper officer or employee, simply because of inadequate provision for privacy. Too few persons see this as a design or office layout problem, insisting that "with proper control the interruptions will be kept at a minimum." The chief of a small or medium-sized department will soon find that the sight of him at his desk, with no one else in the room, indicates to many citizens that he should be available to talk to anyone. Therefore, certain offices should not be located immediately adjacent to the main public entrance unless some screening

or physical separation is provided which allows privacy and freedom of movement to and from the offices.

For the same reasons, offices of the youth unit, the vice unit, and the intelligence unit should be located away from the normal public traffic flow areas. However, they should be relatively close to the police officers' entrance to the records area. Often the desired degree of isolation can be provided by rear entrances or alternate routes of exit. Informants, victims of potentially embarrassing crimes, parents of youths apprehended for offenses, and cooperating officers from other agencies generally do not wish to expose themselves to persons in the building for fear of recognition, injury, or other reasons. The feeling that the department is concerned with their privacy or their personal safety frequently assists investigators in persuading citizens to cooperate in investigations in which they would normally maintain silence. Further, the damage caused by the unexpected exposure of a witness, informant, criminal partner, or an otherwise unknown officer to a suspect who happened to be in the station for some other reason is often irreparable.

The layout of investigators' work areas should be kept simple and free of the honeycomb or cubbyhole design found in many stations. Private offices should be provided only for the commander of the unit in small and medium-sized departments and only for the top-level subordinate commanders in the larger agencies. Investigators should have individual lockers for clothing and equipment required for normal work, with nominal filing cabinet space for paperwork associated with current cases.

A good investigator can seldom justify a private desk and file cabinets, for most of his work will be in the field, in the preparation of reports, and in attendance at court, inquests, and hearings. Many agencies utilize a series of tables or salesmen's desks for the investigators' use while reading records, taking notes, or dictating reports, thus minimizing the need for furniture and space. In such situations, a number of semiprivate interview areas are sometimes provided for questioning witnesses, informants, and other persons. However, responsibility for providing interview facilities for prisoners remains with the auxiliary services element so that prisoners need not be removed from within the security area. The same precautions apply for line-up or show-up rooms, and they should not be placed in the investigative office areas.

The offices of division commanders need not be removed from the general area of their subordinates' work areas, but patrol and traffic personnel assembly and roll-call rooms may be multipurpose facilities some distance from the division offices. Whenever possible, the highest ranking commanders' offices should be close to the chief's office and the conference room.

Other administrative offices such as those used by training personnel, planning, and internal affairs personnel also should be located in the same area so that the command staff will be close to these support units. These working areas also should be predominantly open space with a minimum of private offices or rooms. Modular wall dividers and desk or filing cabinet separators are sufficient to divide space among several major elements performing similar or related work.

One major consideration involves the location, design, and use of the police garage. Generally speaking, no attempt should be made to combine the auto maintenance or storage garage with a prisoner unloading area except in smaller depart-

POLICE STATIONS

ments. The garage and prisoner entrance may use the same door, but there should be a secure "tunnel" or section set aside which would allow the vehicle carrying prisoners to be completely isolated inside the security area after the door is closed. Sufficient space must be allowed so that several prisoners may be taken from the prisoner van without endangering the officers involved. Preferably, this area should not be visible from within the remainder of the garage.

Vehicle storage facilities located inside the garage should provide enough space to house most

vehicles not in use, especially in areas where the weather is severe. The garage entrance should not open directly onto a public street or a heavily used alley unless sufficient space is provided so that police vehicles need not be backed out into oncoming traffic. If also used for maintenance and repair of departmental vehicles, the garage should be provided with additional space for a small office, parts and storage, and the actual repair and maintenance area. If possible, the garage should not occupy prime first-floor space, especially in larger communities where the police

building is situated in the congested downtown area.

A final matter of building design involves the departments' marksmanship program. A department often will need an indoor as well as an outdoor target range, but careful planning minimizes the space required. If properly designed and constructed, the range may sometimes be combined with other training facilities, especially in smaller agencies where the shooting program does not require fulltime use of the area.

By JOSHUA H. VOGEL, AIA

Police stations represent one of the necessary governmental functions requiring careful planning. One of the most serious administrative problems confronting most police forces is lack of adequate or proper space and facilities for a police headquarters and jail.

There are two main objectives to be considered in the construction of the police department building: first, the handling and processing of the prisoners; second, the service to the public. The arrangement should be such that prisoners may be handled within the police department itself, without allowing those prisoners to be in contact with the public generally.

Plans Developed for this Section

The plans shown represent the results of the field survey and study by the police chiefs' advisory committee and subcommittees. Particular attention was given to room sizes and the arrangement in the plan of these various spaces in relation to one another, so as to ensure safe flow of traffic within the building by the public and security control of the prisoners by the police force without unnecessary duplication of staff.

The ideas reflected are based on past experiences with similar police stations now in use, and the explanation which follows each plan directs attention to some of the important elements suggested for inclusion in new structures.

SITE REQUIREMENTS

A. General

Police stations should be planned as if they are to be in a separate location from other structures. If analysis of site locations for a police station permits other structures housing other city functions (such as city hall or fire station) to be erected on the same site without interfering with the proper discharge of functions, then one central site can be chosen.

The jail section of a building should be above the ground and set back far enough from the property line to prevent contact between prisoners and persons outside of the building. Jail quarters should be accessible to a loading space at, or within, the building for the transportation of prisoners. It should be located where the vehicular traffic is not too heavy.

Off-street parking, space for expansion, light and air on all sides, and separate entrances must be provided whenever possible.

Small Cities and Towns

It has been found in small, compactly built cities and towns that one location will serve all city departments under one roof. When the city or town area extends only a few blocks in any direction, access to arterial streets

is readily possible. Such a central site, however, should be so laid out that it gives an opportunity for the public to enter the administration rooms from one street, the fire department from another side street, and the police department from a third side or from the rear.

In all these cases, the location in relationship to the various land uses, the street pattern, and size of the site itself makes it possible that this central site can have all the governmental units in one location and still meet all the site requirements of the individual functions separately.

GENERAL DESIGN INFORMATION

A. Horizontal Plan

A building with the least number of floors is more economical to supervise because less personnel is required to supervise it. While a building of several floors may cost less in construction and be a saving in site costs, the extra outlay for administrative personnel, year after year, will never cease; in time it may be far greater than the additional cost of the desirable horizontal plan.

B. Construction Building Code

The building should be fire resistant, properly lighted, heated, and ventilated. The plans should be arranged to prevent smoke and hot gases, from cooking or heating units, from passing through the building at any time.

Fire safety devices such as standpipes, fire hose, extinguishers, and alarms should be amply provided.

If the building is of two stories or more, two or more enclosed stairways should be provided according to building regulations for fire hazards.

C. Facilities

1. Windows Windows adjacent to jail quarters should have steel bars or steel detention sash with screening devices and be inaccessible to prisoners. All parts of detention quarters should be separated from exterior walls by a mesh partition, parallel to outside walls and 3 ft inside them, to prevent passing of contraband, exhibitionism, and to give passage for supervising personnel.

2. Storage A safe storage place should be provided for cash and valuable articles.

3. Firearms Firearms, weapons, and medicines should be stored in strong, securely locked cabinets inaccessible to prisoners; i.e. they should be kept in locations removed from jail quarters and corridors.

4. Firefighting Apparatus All fire hazards should be guarded against. Avoid exposed electrical installations, wood partitions, straw ticks, paper, rags, and other combustible materials. Fire hose in locked cabinets should be easily

accessible for inspection, for jail personnel to have for drilling, and for use in event of fire or emergency.

5. Telephone, Radio The telephone and radio service should include equipment for fire calls and auxiliary fire alarm as well as provision for right-of-way calls, conference calls, watch calls from stations of duty, and supervisory calls.

6. Detective Division The location of a detective division will depend upon the workload involved and the number of detectives employed. There should be a main detective office large enough to permit all detectives to get together for briefing and instructions. In addition, there should be small rooms located adjacent to the main detective office, which can be used for interrogation purposes. These need not be elaborate and require only a desk and two or three chairs.

7. Show-up Room In case a show-up room is desired, it should be located in such a manner as to permit the shuttling back and forth of prisoners from the confinement quarters to the show-up room without coming into contact with the public.

8. Visitors' Room A visiting room should be provided so as to promote informal interviews under adequate supervision. This visitors' room can serve for visitors for the prisoners or as a conference room between an attorney and a prisoner. It should be so located that the prisoners' entrance is on the jail side and the visitors' and attorneys' entrance is from the public side. A separation between prisoners and visitors inside the room should be provided by at least a fine meshed double screening or heavy plate glass windows. Another type of separation is the use of a table at least 3 ft wide with a partition extending to the floor and the partition above the table running to the ceiling so that it is impossible to pass even the smallest item of contraband.

9. Interview Room A separate interviewing room should be provided for the use of attorneys, probation officers, and social welfare workers.

10. Examining Room This same room, if properly located, can also serve as an examination room for the medical officer. For medical facilities, a locked steel cabinet for the medical equipment can be placed on the wall in one of the examination rooms.

11. Kitchen When the jail averages more than 15 prisoners a day, a properly equipped kitchen has been found advisable. There should be a refrigerator room and locked storage closet. The kitchen should be equipped with a stove for top and oven cooking. If it is a two-story building, one kitchen only on the first floor is recommended and dumbwaiters may be used, with a pantry on the second floor. In cases where the food is brought from the outside and not cooked on the premises, the kitchen or

Police Stations, Planning and Specifications, Bureau of Governmental Research and Services, University of Washington, Seattle, Wash., 1954.

21. Plumbing Adequate water and sewage systems should be provided. Provision for prisoners to obtain drinking water should be provided by the installation of recessed sanitary drinking fountains installed throughout the jail. Bathing facilities (showers) should be available for daily use. In the larger police

22. Receiving Garage A receiving garage should be built immediately adjacent to the building or made a part of it, so that cars could drive

The prisoner booking room, jail, and general office should be arranged so that one officer can book and supervise prisoners, handle communications, and serve the public without leaving the main office. The entrance to the jail and routing of prisoner traffic must be separate from the public area traffic. There should be an enclosed, escapeproof hallway or area for conducting prisoners from the jail to the courtroom.

POLICE STATIONS

B. Police Station—City of 3,500 Population

The floor plan for 3,500 or less population on a small lot on a corner street has all the needed central control but has few offices and a small jail (see Fig. 1).

1. Courtroom The courtroom is located so as to be accessible to men prisoners, while women prisoners can be brought through the office to court.

As the courtroom is sometimes used for special meetings, it is planned to have a separate entrance lobby so the public need not pass through the police station foyer and disturb the office at night.

2. Men's Cells One padded cell, one two-bed cell, and a large tank are provided. The tank can serve as a dayroom in this plan. Beds could be placed in the tank.

3. Multiuse Cells The multi-use isolation cell with two beds can be for isolation, for two inmates, for juveniles, or, in rare cases, it can be used as a women's cell, in which latter case a matron must be called in and the examination room is for her use. The multipurpose cell could be arranged for two two-beds so that altogether six inmates could be accommodated. If beds are placed in the tank, up to ten inmates could be housed.

4. Pantry The pantry is for service and dishwashing in case meals are so arranged. It can be used as a small laboratory if not used as a pantry.

5. Possible Expansion If the particular city has a greater maximum number of prisoners, it should be noted that the men's jail could be expanded into the carport space by placing the carport space farther back on the lot and building more cells on the cell side of the corridor. A dayroom in back of the tank side of the corridor could be provided.

Summary of Requirements

Population: Less than 3,500. See Fig. 1 for plan
Number of Persons in Police Department: Male officers, 4

Parking: Space for police officials' cars and public's vehicles, 4 (min.)

Estimate of Space and Facilities, Requirements for

I. General Police Administration Operations:

A. Executive's Requirements (Room or space sizes in feet):

1. Chief's office: 8 by 14
2. Private entrance
3. Conference room: Combined with courtroom
4. Cooperating officer's room: 8 by 10

B. Records and Clerical:

1. Central records maintenance: Combined with main office, traffic records, and personnel records.
2. Map space: In main office

C. Communications:

1. Telephone and radio: In main office

D. Training:

1. Classroom: Combined with courtroom
2. Library: Combined with chief's office
3. Supplies storage: Combined with main office

E. Identification:

1. Prints: Combined with shakedown room

II. Prisoners and Jail Facilities:

A. Receiving, Processing, and Confinement:

1. Drive-in garage: 12 by 25
2. Booking, searching room: 10 by 10
3. Medical examination room: 8 by 8
4. Isolation cell: One, 7 by 8
5. Violent cell: One, 7 by 7
6. Tank: 12 by 12
7. Dayroom: Combined with tank
8. Toilet: In cells
9. Shower: 3 by 7
10. Attorneys' interview room: 9 by 9
11. Storage: Combined with janitor's room
12. Storage prisoners' property: Vault 4 by 6
13. Prisoners' waiting space to courtroom: 4 by 8
14. Pantry: 6 by 8

B. Separate Rooms, Facilities for Women Prisoners:

1. One multi-use isolation cell: 12 by 12
2. Shower, toilet: 3 by 8
3. Matron's room: Combined with examination room: 8 by 8
4. Matron's toilet: 3 by 8

C. Separate Rooms for Juvenile Prisoners:

1. Use multi-use isolation cell

III. Receiving and Assisting Public:

1. Separate entrance foyer: 10 by 14
2. Public toilets: Men's and women's, each 5 by 10
3. Public telephone: In foyer
4. Complaint counter: Combined with main office, traffic violations and reporting accidents

IV. Police Personnel Requirements:

1. Male locker room: 6 by 8
2. Toilet: Combined with janitor's room

V. Police Property Requirements:

1. Storage of recovered, stolen bicycles: Combined with meter repair, 12 by 24
2. Storage of recovered stolen property
3. Storage of Police Department supplies: 8 by 8, near vault

VI. Police Building Maintenance Requirements:

1. Janitor's room: 6 by 10
2. Boiler and fans: 10 by 10
3. Heating, ventilating: Combined with boiler room
4. Repairs: Combined with meter repair room

VII. Courts:

1. Police courtroom: 16 by 23
2. Clerk's office: Combined with attorney's room, 9 by 9
3. Attorney's room: Combined with interview room

VIII. Public Safety Education:

1. Safety: Combined with main office

C. Police Station—City of 7,000 Population

The plan shown in Fig. 2 for 7,000 population is for a narrow site on a street corner.

1. Offices and Courtroom Offices for officers and the central record office and courtroom are provided. A 4-ft wall space is needed for the intercommunication system in the office. The attorney-clerk's room must serve also as

visitors' room in conjunction with prisoners' waiting hall back of the courtroom.

The matron's office must serve for visitors' room for women; and the attorney-clerk's office, in conjunction with the corridor for men prisoners, must serve for visitors' room for men.

2. Women's Jail The women's cell for four inmates and adjacent cell for two inmates could be used for juvenile or isolation cells.

3. Pantry The kitchenette is a pantry for serving food brought in from outside and placed in trays, and for dishwashing.

4. Men's Jail For men there are two isolation cells, one padded cell, and four four-bed cells, thus housing 18 men besides those in the tank. Dayroom for the privileged is provided.

Summary of Requirements

Population: Less than 7,000, See Fig. 2 for plan.

Number of Persons in Police Department: Male officers, 8 to 10

Parking: Off-street parking area for police vehicles adjacent to the police building; 2 cars. Area required for parking cars of persons who visit police headquarters; 2 cars. Total, 4 cars (min.).

Location of Police Headquarters Facilities: In the business district or manufacturing district. The building should be by itself if possible. If not, with the city hall. If it is combined, the lights, heating, and ventilation for the police department are to be operated separately. The police station should have separate entrances, one for the public and one for prisoners.

Estimate of Space and Facilities, Requirements for

I. General Police Administrative Operations:

A. Executive's Requirements (Room or space sizes in feet):

1. Chief's office: 11 by 14
2. Private entrance: Yes
3. Conference Room and Classroom: Combined with courtroom
4. Chief's office toilet: 3 by 8
5. Chief's office clothes closet: 2 by 4

B. Records and Clerical:

1. Central records maintenance: Combined with main office, traffic records, and personnel records
2. Map space: In main office
3. Mimeographing: In main office

C. Communications:

1. Telephone and radio in main office
2. Public telephone in foyer

D. Training:

1. Classroom: Combined with courtroom
2. Library: In chief's office
3. Firearms range: At city sportsmen's range
4. Supplies storage: Combined with main office

E. Identification:

1. Photographing and Fingerprinting room
2. Darkroom: 6 by 10
3. Lineup or show-up: Combined with courtroom.

II. Prisoners and Jail Facilities:

A. Receiving, Processing and Confinement:

1. Drive-in garage: 12 by 24
2. Booking and searching room: 10 by 10

Governmental and Public

POLICE STATIONS

3. Medical examination room: Combined with booking room
4. Isolation cells: Two, 7 by 8 each
5. Violent cells: One, 7 by 7
6. Group cells: Four, four bunks each
7. Tank: 10 by 12
8. Dayroom: 12 by 19
9. Toilet and shower room: One in dayroom

10. Attorneys' interrogation room: 8 by 8
11. Prisoners' visiting: Space in corner courtroom
12. Matron's room: 7 by 10
13. Storage, bedding: 7 by 14
14. Storage, prisoners' property: Vault 5 by 5
15. Enclosed vestibule to prisoners' waiting space: 3 by 12

16. Prisoners' waiting space adjacent to courtroom: 3 by 10
17. Kitchenette-pantry: 7 by 12
18. Food storage: 4 by 7

B. Separate Rooms for Women Prisoners:

1. One group cell: 12 by 12, four bunks
2. One isolation cell: 8 by 10
3. Shower, toilet
4. Matron's room: Combined with examination room, 7 by 10

III. Receiving and Assisting the Public:

1. Separate entrance foyer: 8 by 15
2. Public toilets: Men's and women's: Each 6 by 6
3. Public telephone: In anteroom
4. Complaint counter: Combined with traffic violations' bureau and traffic accident reporting counter

IV. Police Personnel Requirements:

1. Male locker room: 8 by 10
2. Coffee bar: Combined with kitchenette

V. Police Property Requirements:

1. Storage of recovered stolen bicycles: 14 by 14
2. Storage of recovered stolen property

VI. Police Building Maintenance Requirements:

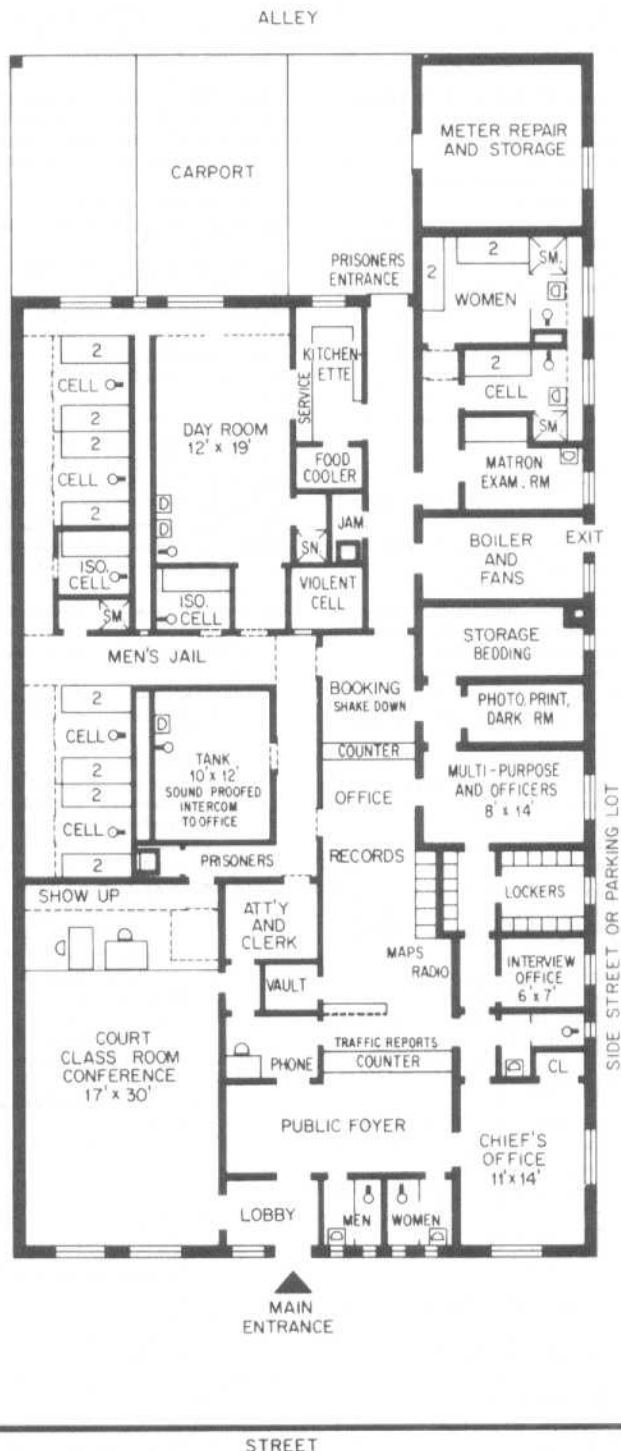

1. Janitor's room: 4 by 7
2. Boiler and fans: 8 by 14
3. Heating and ventilating system
4. Electrical controls
5. Water controls

VII. Courts:

1. Police courtroom: 17 by 30
2. Court clerk's office and city attorney's office: 8 by 8

VIII. Public Safety Education:

1. Safety education office: Combined with main office

POLICE STATION—CITY OF 15,000 POPULATION

A. Plan

The sketch plan illustrates how arrangements provide for central control with public and private entrances and separated, isolated quarters for juveniles, men, and women without any necessity for different classes of prisoners to cross each others' quarters or intermingle.

For 15,000 population or less, a plan of a one-story building is shown in Fig. 3.

B. Room Spaces

1. Central Offices All the necessary offices for administrative functions are provided. Offices for chief and assistant officers are accessible to the jail or to the public. The public, however, is separated from prisoner areas. The main office oversees the whole first floor with a minimum of personnel on duty at any one time.

2. Courtroom, Prisoners' Waiting Room The courtroom has the public entrance at one end, and at the other end the prisoners' waiting room adjoins. In this case the prisoners' waiting room is also arranged to be used in conjunction with the visitors' room.

3. Booking Room The booking room or shake-down is central to the men's jail and the juveniles' or women's quarters. The interrogation room can also be used as a matron's office as needed.

Fig. 2 Plan of police station for city of 7,000 population. One story, lot 50 by 100 ft; building 4,300 sq ft.

4. Juveniles' Women's Cells There are cells for four juveniles. For the women's jail, there is a cell for four inmates and a small tank, which can also serve as an isolation cell.

5. Men's Jail For the men's jail there is one eight-bed group cell which can be used for trustees, two isolation cells, one padded cell, and one sixteen-bed and one eight-bed group cell with dayrooms. A maximum number of 34 men can be housed, besides those in the tank.

6. Second Floor Alternate It should be noted that if the men's jail is on the second floor, the jail quarters are not over the juveniles' or women's jail quarters. Intercommunication thus is impossible and there are no special construction problems. The second floor, however, requires one more officer on duty than would be required in the case of the one-story plan.

7. **Stairs** The enclosed passage and/or stairs to the courtroom for men prisoners is provided for whether a one-story or a two-story plan is adopted.

Summary of Requirements

Population: Less than 15,000. See Figs. 3 and 4 for plans.

Parking: Off-street parking area for police vehicles adjacent to the police building: 6 cars. Area required for parking cars of persons

who visit police headquarters; 3 to 6 cars.
Total, 9 to 12 cars (min.).

Estimate of Space and Facilities, Requirements for

I. General Police Administration Operations:

A. *Executive's Requirements* (Room or space sizes in feet):

1. Chief's office: 12 by 12 to 12 by 15
2. Private entrance: 3 by 6
3. Conference room: 10 by 10
4. Chief's office toilet: 6 by 8
5. Chief's office clothes closet: 2 by 4
6. Assistant chief's office: 9 by 10
7. Chief's secretary's office: Combined with main record room, 10 by 17
8. Other: waiting room or public lobby: 15 by 20

B. Records and Clerical:

1. Central records maintenance, in main office, 12 by 18
2. Map room and library (accidents and crime data): Combined with officers' briefing room, 9 by 15
3. Old records storage: 4 by 6
4. Men staff toilets and lockers: 8 by 10
5. Women staff toilets and lockers: 8 by 10
6. Meter repair room: 10 by 12

C. *Communications:* Combined with general office

D. Training:

1. Classroom: Combined with courtroom, 17 by 24
2. Library: Optional, 10 by 12
3. Firearms range: 15 by 70
4. Supplies storage: 6 by 6

E. Identification:

1. Photographing and fingerprinting rooms: Combined with record room, 9 by 12
2. Photographic dark room: 6 by 8
3. Identification records: Combined with main office
4. Storage: 6 by 6 or combined with hall lockers
5. Lineup or show-up: Combined with courtroom

F. Office for Use of Other Enforcement Agencies' Representatives (Military Police, Federal Agents, Parole Officers): 10 by 10, optional

11. Prisoners and Jail Facilities:

A. Receiving, Processing, and Confinement:

1. Drive-in, escapeproof garage:
15 by 25
2. Booking and searching rooms:
10 by 12
3. Physician's office and medical
examination and treatment

(a)

POLICE STATIONS

- rooms: Combined with interrogation room
4. Isolation cells: Two, 7 by 8 each
 5. Violent cells: One, 6 by 7
 6. Group cells: Two, 8 by 13
 7. Cellblock: One 10 by 24; One 15 by 24
 8. Tank: 12 by 17
 9. Dayroom: Two, 9 by 20 and 12 by 20
 10. Toilet in cells and shower room: Two, 4 by 6
 11. Attorneys' interrogation room: 9 by 10
 12. Prisoners' visiting room: 8 by 8
 13. Delousing room: 6 by 6
 14. Laundry: 8 by 8
 15. Storage, cleaning utensils: 9 by 13, combined with storage
 16. Storage, bedding: 6 by 8
 17. Storage, prisoners' property: 4 by 6, or lockers
 18. Prisoners' waiting room adjacent to courtroom: 7 by 8
 19. Kitchen: 8 by 10
 20. Refrigerator: 4 by 6, optional
 21. Food storage: 4 by 6
- B. Separate Rooms for Women Prisoners:**
1. One isolation cell: 8 by 12
 2. One violent cell: 7 by 7, optional
 3. One tank: 9 by 10
 4. One shower in tank, one in cell, toilet in each cell
 5. Matron's room: 10 by 14, plus 4 by 6 toilet optional

- C. Separate Rooms for Juvenile Offenders:**
1. Two cells: 7 by 8
 2. One shower, One toilet in cell
- III. Receiving and Assisting Public:**
1. Separate entrance
 2. Public waiting room: 10 by 14 to 15 by 24
 3. Public toilets: Men's and women's, 8 by 8 each
 4. Public telephone: One pay phone, 3 by 3
 5. Information center: Desk sergeant
 6. Complaint counter: Combined with general office, 12 by 18
 7. Traffic violations bureau: Combined with complaint counter
 8. Traffic accident reporting counter: One 3 by 5 desk
- IV. Police Personnel Requirements:**
1. Male employees' lounge: 10 by 12, optional in basement
 2. Male locker room: Ten lockers in 9 by 12 room
 3. Women's locker room: One locker in women's office toilet
 4. Male shower and toilet room: Two toilets, one shower combined with lounge
 5. Gymnasium: 27 by 23, in basement
 6. Lunchroom and coffee bar: 9 by 10, in squad room in basement
- V. Police Property Requirements:**
1. Storage of uniforms: Lockers in basement

2. Storage of guns and ammunition: 5 by 6
 3. Storage of police vehicles: Two cars, 20 by 24
 4. Storage of recovered stolen bicycles: 10 by 12
 5. Storage of recovered stolen property: Combined with storage
 6. Storage of police department supplies: Two cupboards in officers' room
- VI. Police Building Maintenance Requirements:**
1. Janitor's room and lockers: Closets on each floor
 2. Boiler and fuel: 14 by 16
 3. Heating and ventilating system
 4. Electrical controls: Emergency 8 kva electric generator unit for radio and lights
 5. Repair and construction: 12 by 15
- VII. Courts:**
1. Police courtroom: 18 by 33, Combined with courtroom
 2. Judge's chambers: 9 by 9
 3. Court clerk's office: Combined with item 2
- VIII. Police Divisional Operations:**
- A. Detective Division:**
1. Office of officer-in-charge: 8 by 10, Combined with interrogation or assistant chief
 2. Interrogation rooms: 8 by 8, Combined with examining room
- B. Women's (Morals) Bureau:**
1. Office of officer-in-charge: 9 by 15, Combined with interrogation room
- C. Juvenile Division:**
1. Office of officer-in-charge: 8 by 10, Combined with interrogation room
- D. Public Safety Education:**
1. Bicycle licensing room: 8 by 10

Fig. 3 (cont.) Plan of police station for city of 15,000 population. Building 6,000 sq ft. (a) First floor plan. (b) Second floor plan.

DESCRIPTION OF PLAN FOR A SMALL TOWN HALL WITH POLICE STATION

A. Site Location

The site location can be anyplace centrally located in town. Distances across a small town are too short to present special problems. Usually the fire department is a rural fire district with the fire station located on separate property, although it could be on the same lot. In some cases the library can be planned on the same site if the entrance is on the opposite side from the prisoners' entrance.

B. Plans

A plan of a small town hall is shown in Fig. 4.

C. Room Spaces

1. Court and Council Room For a small town in a rural fire district, with few utilities to operate, a combined city hall and police station is desirable, as the council room can serve as a courtroom, and only one heating unit is needed.

2. City Hall Offices To provide for best use of personnel, since the clerk-treasurer may serve only part time, the marshal's office is located to oversee the town hall's public lobby as well as the prisoners' entrance and jail. The requirement of reporting traffic accidents warrants the office being kept open daily.

3. Offices This small plan has an office for the mayor or conference room, one clerk-treasurer

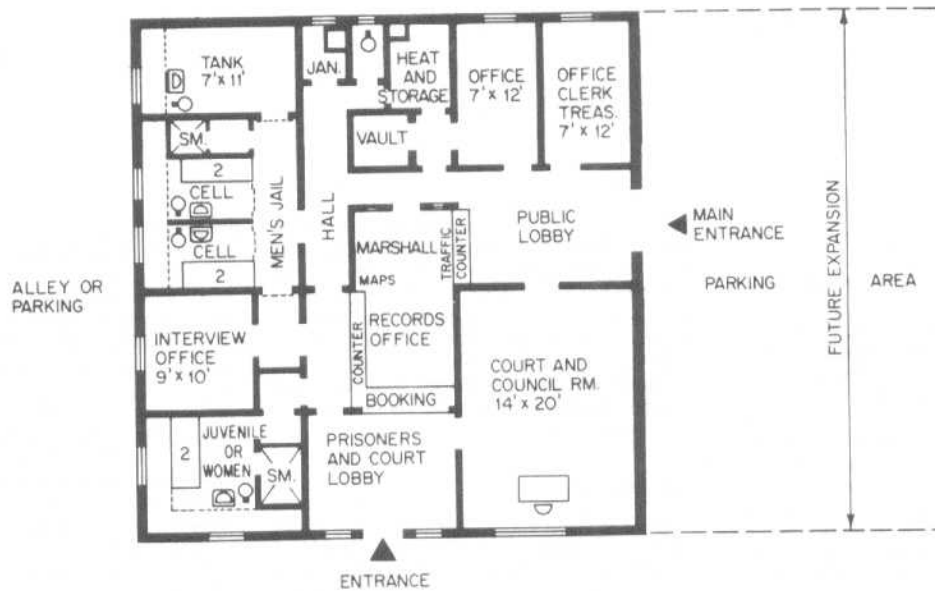

Fig. 4 Small town hall with police station.

office, a vault used by the marshal and city clerk, and a court-council room. The records room and the marshal's office are in one unit.

4. Juveniles' and Women's Cells One two-bed isolated cell can serve for juvenile or women prisoners, or as an isolation cell. Seldom is it needed for all such uses at the same time.

5. Men's Cells The men's jail includes the tank and two two-bed cells. Altogether six inmates, besides those in the tank, can be housed. Toilets and heating plant are included.

POLICE FACILITY

SITE SELECTION

Accessibility

From a total program standpoint, several possible sites should be inspected for a proposed law enforcement building. Several factors should be taken into consideration when selecting the site including location, available land area, configuration, and relationship of the site to major arteries and main highways that extend throughout the area. Additionally, the relationship of the proposed building to existing governmental structures should be considered, with particular emphasis placed on the relative proximity to the existing courts, jails, and prisons.

Primary consideration should be given to the selection of a site that will provide maximum accessibility to the community being served. The facility should be as close to the centers of business, industries, schools, welfare agencies, and the courts as circumstances permit and in an area which can be served by public transportation. Not only will this facilitate the use of such resources, but problems in staffing are simplified when there are not tiring and complicated daily trips to and from the facility. For prisoners who are selected to participate in programs of work release, study release, clinical services, or other community activities, transportation problems can contribute heavily to the success of such programs.

The facility should be easily accessible to the public and not hidden on a side street or on a site with very limited street frontages. The building should be related to one or two of the main streets connecting both north and south and east and west portions of the city. The building should not face an extremely busy highway or through-city thoroughfare, which might make access into the traffic lanes difficult.

The site should be accessible to two streets, rather than one. Several entrances and exits should be provided for police vehicles to ensure immediate access and egress to and from the site in the event one of the entrances might be temporarily blocked.

Residents can best be served by the central location of all criminal justice components and activities in a centralized design concept.

Parking

The site should be adequate, not only for the building itself, but to accommodate a police motor-court activity, staff parking area, and public off-street parking requirements. The parking space allocated for employee vehicles and for police vehicles is important when making shift changes and removing prisoners to and from jail. In the case of a combined police/jail facility, a private jail booking entrance (sally port) and prisoner processing area, easily accessible to automobiles, should be included in the plans.

In some instances, a basement-level parking

garage for police vehicles may be desirable. A ramp leading from the basement level would provide adequate street access. Placing the garage and official parking facilities in the basement will reduce noise levels at shift change times and during the conduct of daily activities, thereby avoiding inconvenience to adjacent land owners.

The parking lot or roof of the structure should also be considered as a possible site for a helicopter landing pad.

THE BUILDING

A police building should be regarded as a viable and flexible structure. It should be capable of growing with the community and the department it serves. The architect should be fully aware of the growth potential of the department and should design a facility that will meet not only the present needs of the agency, but also its future needs.

Police Function Only

Ideally, the building should house only the police component of the criminal justice system. Except in very small communities, the building should be exclusively oriented to the police function. Consideration should be given to separating the police from the incarceration function and the associated stringent design features necessary when the jail is made a part of the police building.

Similarly, the judicial functions would best serve the needs of the people if they were not located in the same building as the police. The framers of our Constitution made it perfectly clear that there must be separation of power between the executive, legislative, and judicial branches of government; therefore, we urge physical separation of the police facility, the courts, and the jail.

Exterior Design Philosophy

All public buildings should reflect an atmosphere of restrained dignity, permanence, security, beauty, and strength. It is imperative that a police facility impart the sense of strength and permanence to a greater degree than other governmental structures. To the public, the police building should represent a friendly, businesslike, professional building complex. Security provisions must, of course, be incorporated into the design because of the volatility of our times; however, it is possible to artfully disguise them so that the fortress image is not the predominant feature of the structure.

The police facility should be constructed of non-combustible materials. The design of the building, including the exterior surfaces, landscaping, and other elements, should be planned to reduce the number of areas where explosives may be hidden. Reinforced masonry on the exterior walls and either concrete or a lightweight concrete layer on the roof, will improve the building's resistance to manmade [sic] or natural disasters. Many refinements to increase building safety and security can be provided at little additional cost. All or most of the glass areas, both interior and exterior,

should be of bullet-resistant material. An interior garden court could be one of the methods used to create a quiet, beautiful, and serene atmosphere that could psychologically benefit the entire staff and eliminate the feeling of being enclosed in a windowless fortress. Whenever possible, the exterior of the building should not include windows.

The so-called "windowless" building may contain considerable glass, but the glass is positioned in such a manner that none of the interior activities can be viewed from the exterior areas. Psychologically, glass used in this manner can completely eliminate the feeling by the staff that they are working in a windowless facility.

The police building should be designed to provide services to the public as well as to fulfill the everyday working needs of the police. The structure should be readily accessible with ample public and private parking space. Properly designed landscaping, flagpoles, and identifying illuminated signs can and should be attractive and functional components of the building.

Horizontal Plan

A building with the least number of floors is more economical because less personnel are required to supervise it. While a multistory building may cost less in construction and be a saving in land costs, the extra outlay for administrative personnel, year after year, will never cease. In time, it will probably be far greater than the additional cost of the more desirable horizontal plan.

The horizontal design philosophy lessens the need for stairs and elevators which, when utilized, add hazard potential when moving prisoners, for bomb placement, for fire, and so on.

Human Needs

A law enforcement agency deals with many people. Basically, however, they can be divided into three categories:

- Department personnel
- General public
- Prisoners

Each group has specific needs in a police building and the needs of each should be considered as they relate to the entire facility.

Department Personnel The term "department personnel" includes all employees of an agency—executives, managers, supervisors, officers (both uniformed and plainclothed), clerical, and special employees.

Uniformed personnel who constitute the bulk of employees usually report to a central location which should include lockers, showers, and physical exercise area. A briefing room with the capacity to accommodate approximately two-thirds of the patrol force should be located near the locker rooms. A separate entrance into the building should be provided for use by police employees only. Unnecessary mingling of police officers, the public, and prisoners should be avoided in the police facility.

Police Facility Design, Bureau of Operations and Research, International Association of Chiefs of Police, Gaithersburg, Maryland, 1978.

POLICE FACILITY

General public The majority of persons visiting the police headquarters will have business only at the central information center. Therefore, the public information lobby should be a part of the information center operation and should be easily accessible from the *main entrance*. Employees in the information center can then handle inquiries and refer callers to the proper official or office. As a general rule, the building should be planned and equipped to avoid confusing the public. Offices should be plainly designated by functional titles on the doors. A conveniently placed building directory in the lobby is also an important feature that should not be overlooked.

Prisoners When the jail facility is located within the police building and/or when prisoner booking is done at police headquarters, special design features must be incorporated to accommodate this function. Prisoners should enter the building through a separate secure entrance. A sally port with automatic doors and drive-in provision should be part of the security entrance. A model prisoner-processing arrangement is shown in Fig. 1.

The reader should refer to Fig. 2 to better understand the relationship of the three separate entrances, public parking, employee parking, and police vehicle parking. Note in Fig. 2 the security feature of the gate separating the police vehicles from public access. Whenever the police facility is located in a residential area, high shrubbery and, more preferably, a masonry wall surrounding the police parking area should protect the adjacent residents from the glare of vehicle lights at night.

Interior Design Features

One of the basic requirements of a functional floor plan in a modern police facility is the control of internal circulation. Efficiency and safety dictate that the public enter the building through a single entrance into a controlled lobby. The public should not penetrate beyond the lobby

and should be allowed further access only after the need has been demonstrated. Figure 2 shows the functional relationships of the three entrances.

Space Allocation The functional police facility should be as flexible as possible for efficiency and economy. A flexible building is one in which

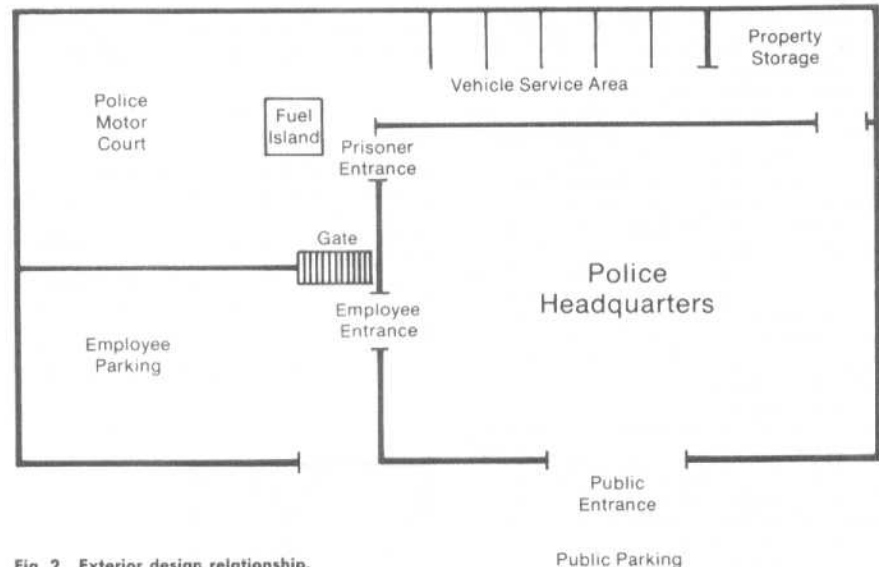

Fig. 2 Exterior design relationship.

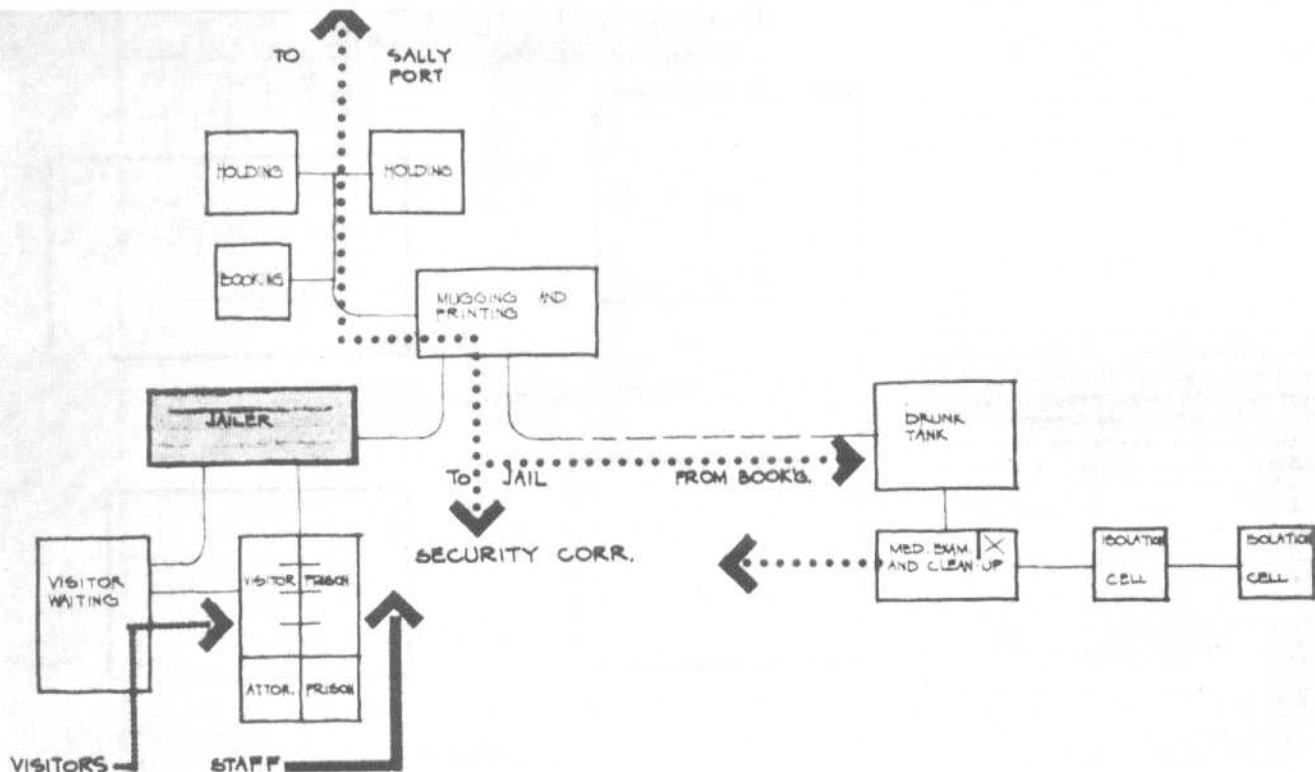

Fig. 1 Model prisoner-processing arrangement.

POLICE FACILITY

the interior space is adaptable to a broad variety of occupancies and the exterior walls are expandable to meet future growth needs.

In some cases, interior flexibility may be attained by the installation of movable partitions which can provide necessary privacy and also may be shifted to meet future functional space needs. Partitions approximately 6 feet in height afford sufficient privacy without affecting light or air conditioning. Private offices and small rooms should be kept to a minimum.

Private offices make supervision more difficult; occupants are tempted to turn their attention to outside matters and to engage in activity not strictly police-related. The potential for this situation is lessened when the partitions forming the offices are glass and, in some instances, the partitions may be less than ceiling height.

Glass partitions facilitate supervision and tend to assist in maintaining a businesslike appearance on the part of personnel by providing an unobstructed view for supervisors. Each area that must be kept secure, such as places where prisoners are confined or moved, the communications center, and areas for property and evidence storage, require special design features. Permanent partitions should be used in these areas and wherever the need is justified.

The building should contain large open floor areas in which a broad variety of furniture and equipment may be arranged. These areas may be subdivided with a minimum of structural or mechanical operation and expense through the use of standardized, movable, and interchangeable nonstructural elements.

Space can also be separated effectively by counters. The counters can also serve as receptacles for file cabinets.

ADMINISTRATIVE AREA

One portion of the police facility should be reserved exclusively for the administrative command staff. This staff includes the chief of police, planning and inspection services commanders, and the commanders of the primary organizational entities with departmentwide jurisdiction, such as the uniformed division, criminal investigation division, administrative services division, and technical services division.

Chief of Police

Immediate public access to the chief of police is not always necessary or desirable. Many citizens with minor problems, who at first demand to see the chief, can have their problems adequately resolved by talking to subordinate personnel. Constant interruptions of this sort would distract the chief from his primary obligations to the department. Thus, we recommend an office area that is away from the mainstream of public and staff, preferably near the rear of a one-story building or on the second floor of a two-story building. It is customary and worthwhile for the chief to have a private entrance, private toilet facility, closet, and a conference room immediately adjacent to his office. The normal space allowance for the chief's private office should be approximately 300 square feet. The separate conference room should be large enough to seat all officers above the rank of lieutenant, i.e., the executive staff. Access to the conference room should be from both the chief's office and from a common hallway for staff use.

The chief should be provided with a private secretary and, in larger agencies, an administrative officer. These two staff assistants should, of

course, be provided sufficient office space immediately adjacent to the chief's offices.

Figure 3 shows model layouts for the office of the chief of police in cities of varying size. Figure 4 shows model layouts for conference rooms.

Executive Command Staff The chief's executive staff should occupy offices which surround his own. Each staff office should be approximately 200 square feet in size. These staff offices could conceivably share secretarial services, e.g., one secretary for every two staff commanders.

CENTRAL RECORDS AREA

Records

The public entrance into a police facility should be primarily through a single main entranceway into a common lobby. This single public entrance should be controlled and supervised from the central records center.

This central records center should be placed in full view of the main facility entrance. The location should be such that records personnel can individually screen all citizens entering the building. Provision should be made in the lobby

area for public seating, public telephones, showcases for display of exhibits, and public restrooms. The public restrooms should be constructed of materials that would limit damage to the building in the event of a concealed, incendiary explosion.

The records area should be separated by glass from the public areas and staff access counter to ensure complete security of the entire records area.

The majority of persons visiting the police station will have business at the records center. Therefore, a public counter should be part of the records center. The employees in the records center can then handle inquiries or refer callers to the proper official or office. As a general rule, the building should be planned to reduce the necessity of having the public wander about the building seeking assistance. Public circulation within the building should be controlled and limited by separating the public lobby area from other corridors and doors that should be controlled electrically.

The interior of a police facility should be decorated in a professional manner. Bright, warm, but soft colors combined with careful use of complementary accents should greet the public. Rotary records systems should enhance the appearance of the records center as well as provide for a

Fig. 4 Conference rooms.

POLICE FACILITY

functional records storage and retrieval operation.

The records room, in addition to serving the public, should also be the center for collection and dissemination of information to police officers. Therefore, a private counter should be provided for police officers so that they may more effectively utilize records without using the public area and without permitting them complete freedom of access to the records room itself. Only

personnel assigned to the records function should be permitted in the room. This recommendation is made to preserve the integrity of the records and accountability for their proper maintenance.

The size of a records area should, of course, reflect the needs and space requirements of personnel assigned to the records function. A useful guide, when in doubt as to size, is to allocate approximately 100 square feet of space for each 15 police officers in the department.

Because of the heavy floor weight that will be required in the records area of the building as a result of files and other equipment, structural design requires that the floor be reinforced.

A model police information center is shown in Fig. 5.

COMMUNICATIONS

Dispatching Facilities

The police communications command center and its related equipment should be isolated from public contact in one of the more secure areas of the building. Other electrical and mechanical systems should also be protected to reduce the possibility of sabotage or vandalism.

Most police practitioners would agree that locating the dispatching and records units in close proximity offers advantages of expediting the flow of information and makes more efficient use of personnel. This philosophy is most practical in small agencies where a minimum number of persons on a late tour of duty could conceivably handle both communications and records responsibilities. When this arrangement is necessitated by department size, we recommend that the entire records and communications area be bullet-resistant.

Radio Console In addition to radio, the dispatch console should contain all electronic systems such as television surveillance of the jail and outside of the building, smoke and fire detection and warning devices, detention area audio surveillance, remote control for doors, and vehicle status boards, recorders, intercom, and TV monitors.

Status Board Status boards are devices used to indicate the availability of field units. Such a device is justified as a dispatching aid in the smaller as well as the larger departments. Switch control pilot lights may be used, with indicators at each dispatching position, on a large map visible to all positions. The switches must be wired so that actuation in any position causes the same indication at all other positions. Placing of pilot lights on a large map showing beat boundaries is particularly valuable to dispatchers responsible for deployment of large numbers of field units. Each unit's status cannot be accurately recalled from memory, nor can time usually be taken to query a number of units to determine which is the closest to the assignment at hand.

Recording Device The elimination of the log-keeping requirement by the FCC, which for many years required a transmission by transmission entry in a written form, has eased the dispatching burden considerably. However, the value of such a record for internal administrative purposes remains. The use of a multichannel tape recorder to fulfill this need is recommended. Space should be allocated for such a device when designing the communications center.

Complaint Operator/Dispatcher

Two types of complaint/dispatch operations are generally acceptable, depending upon the size of a particular agency. In the smaller departments, a single person usually can handle both the complaint-reception function as well as the dispatch operation. Whereas, in the larger agencies, complaint processing may require extensive specialization, perhaps with operators subdivided for geographical areas of responsibility. An alternate approach to the latter is to combine the complaint operators' and dispatchers' duties in

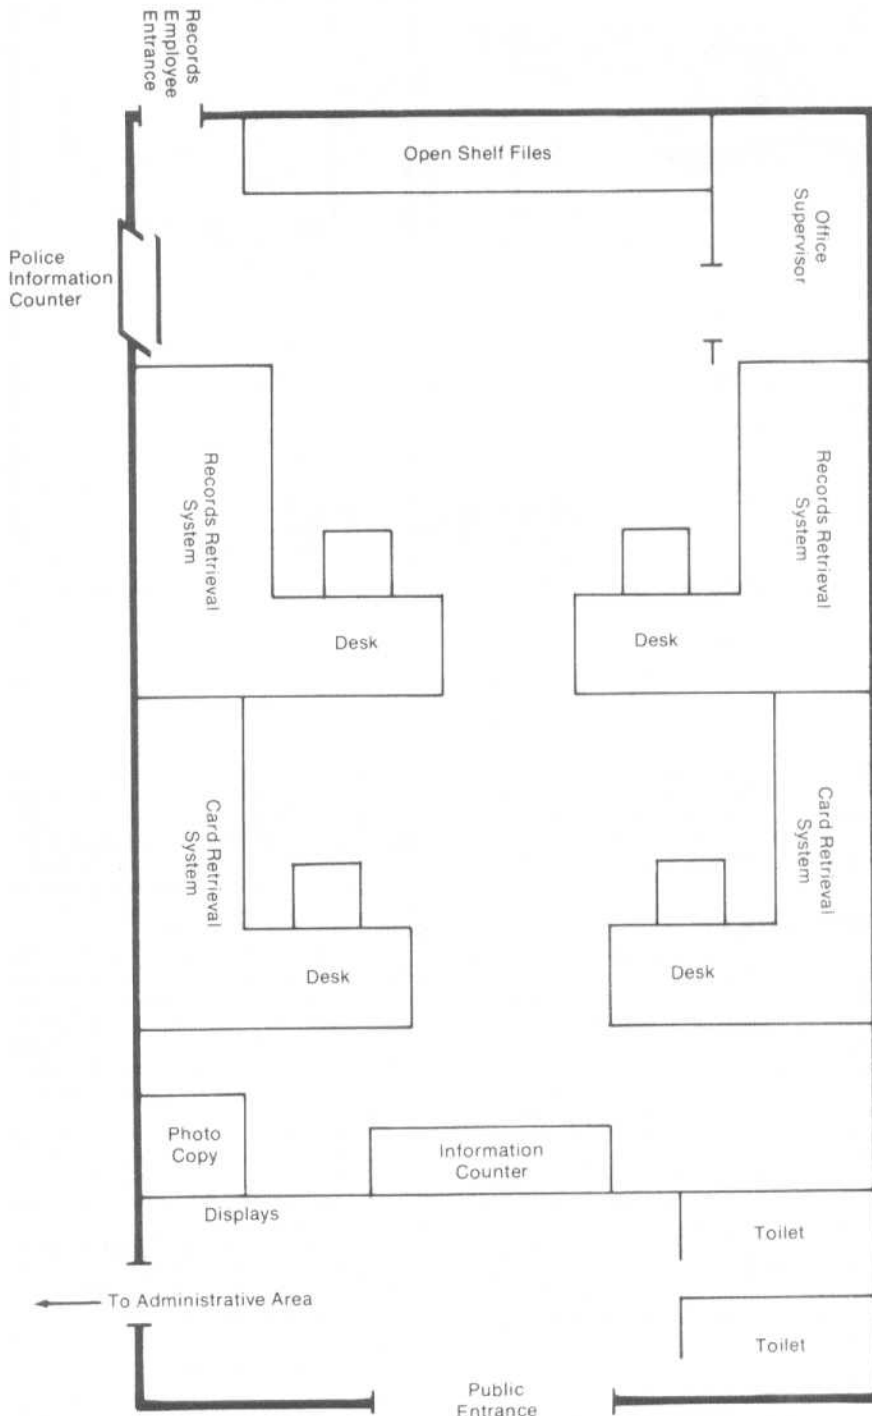

Fig. 5 Model functional space design, police information center.

POLICE FACILITY

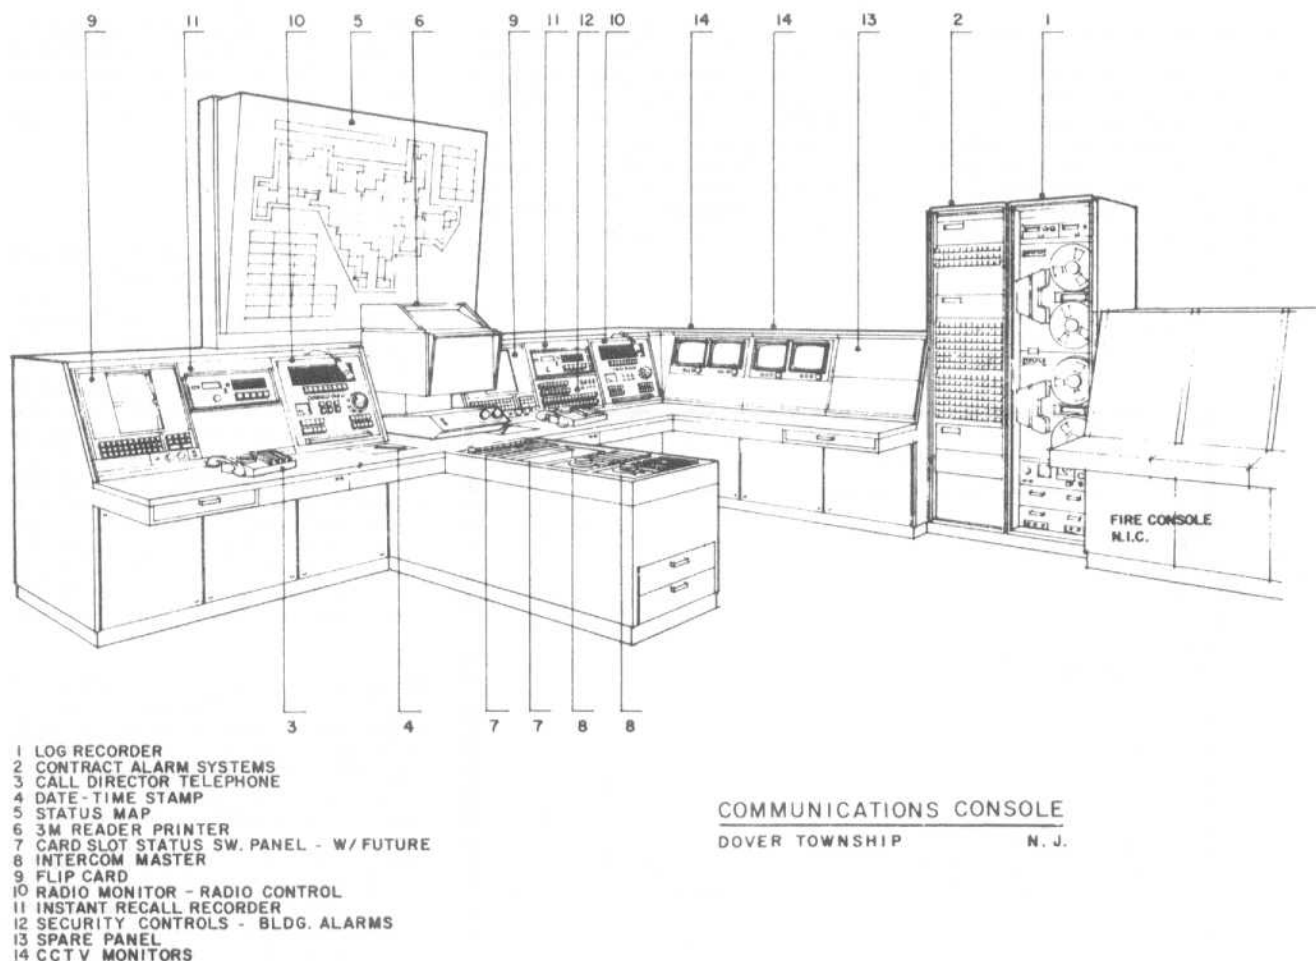

Fig. 6.

one position and add personnel as message volume demands. Difficulties arise in this method, however, when the message volume would justify either a separate complaint operator and a dispatcher or two combined operators/dispatchers (or any multiple thereof). The architect and the agency consultant will have to make the decision as to individual agency needs regarding communications according to the volume of complaint traffic, prior to the design of the command center.

Command Center Supervision

The function of supervising a police communications center should not pose any unusual problems arising out of the nature of the task. The sensitive nature of the process demands at least constant availability of supervision. In larger installations, provision should be made for the supervisor to monitor both landline and radio communications as they are carried on; performance of complaint operators and dispatchers may thus be evaluated to determine training needs and to correct improper procedures. A monitoring position is also useful for instruction of newly assigned personnel, and for intercepting and/or assisting in high priority calls.

Environmental Considerations

The communications command center should be made adequate in terms of sound conditioning,

lighting, air conditioning, room configuration, ability to expand facilities, and total security from potential sabotage. This area should be a complete self-contained unit with toilet, lunch room, locker space, and supervisor's area. See Fig. 6.

Emergency Power Supplies

Radio and landline communications are vulnerable to several influencing factors, the most important of which is electrical power. In the event of failure of normal power sources, the communications center should have some method of obtaining standby electrical service to the base station to insure its continued operations; therefore, the base station should be equipped with an emergency power source. This equipment should be capable of supporting not only all communications equipment, but also lighting requirements for the command center and primary operational portions of the building.

Figure 7 is intended to provide the reader with a visual display of a conceptual design model for a communications command center where telephone reception and dispatching are performed by the same person.

CRIMINAL INVESTIGATION AREA

Several design features should be considered when allocating floor space for criminal investiga-

tors. Investigators make extensive and constant use of records; therefore, it is practical to place investigators as near as possible to the records center. A great number of people coming to the police facility do so in order to confer with investigators; public access is an important feature that must be considered when physically locating detectives.

The area allocated to detectives should provide for individual work space and a degree of privacy for each officer. Collectively, however, detectives should be in constant contact with one another. Therefore, a single spacious room is recommended to house all detectives. The room could then be divided into individual office areas by movable partitions.

Interrogation rooms are another important feature that should be located near the detectives.

Again, in the same general vicinity, the architect should provide for office space for both the unit commander and supervisors.

Figure 8 shows a practical solution for all of the individual requirements needed in order for detectives to conduct their daily operation.

Figure 9 shows model interview rooms.

UNIFORMED OPERATIONS AREA

Although uniformed operations requires the largest number of officers, the physical space needs in a police facility for uniformed personnel are

POLICE FACILITY

Fig. 7 Model communications command center.

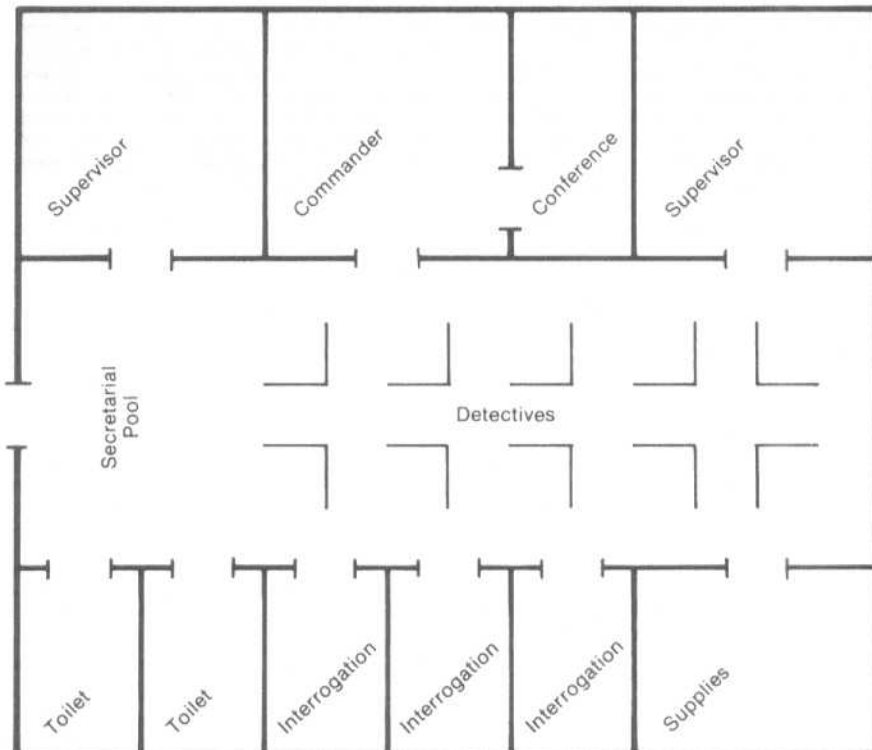

Fig. 8 Model detective area.

substantially less than those of other departmental units. Uniformed officers, of necessity, must remain to a great extent in the field. They require the use of a locker room, toilets, squad room, physical exercise area, briefing room, and writing area.

Commander/Supervisor

The patrol commander and/or shift supervisor should have an office accessible to the public, uniformed personnel, and the communications center. The close proximity to the communications center is important so that the commander can assist dispatchers, or take over the operation when necessary, under emergency conditions.

Special Operations

Office space should also be provided for traffic and tactical supervisors. These offices should be of sufficient size to accommodate crime and traffic accident location maps, charts, and other crime, accident, and special event analysis materials.

Roll-Call Room

Uniformed personnel, who constitute the bulk of employees, will report for roll call (briefing) prior to going on their assignments. Special features of a roll-call room should be planned by the architect. It is wise policy to have this room as private as possible. The public, upon seeing numerous members about an office (especially uniformed members), inevitably concludes that they are non-productive. Roll call, with its attendant inspection, training, reading of orders, and special instructions, should be conducted in a place out of public view. It is equally important to provide space, which cannot be seen by the public, where officers may prepare reports that are not completed in the field because of time or importance.

Special Features

It is wise to plan for a recreation area and lunch area with commissary provisions. The recreation area should be large enough to accommodate

$$\begin{array}{r} 8 \times 18 = 144 \\ +29 \\ \hline 173 \text{ S/F} \end{array}$$

TWO INTERVIEW ROOMS WITH MONITOR

$$\begin{array}{r} 8 \times 8 = 64 \\ +13 \\ \hline 77 \text{ S/F} \end{array}$$

INTERVIEW ROOM FOR TWO OR THREE PERSONS

Fig. 9 Interview rooms.

POLICE FACILITY

a universal gym and other physical exercise equipment that would encourage officers to maintain excellent physical condition, as well as provide space for defensive tactics and other training.

Squad or roll-call rooms should be designed so that desired privacy can be maintained during roll call and training sessions. Lockers should not be placed in these rooms thereby making it necessary for officers to change clothes or use lockers while the roll call for the next shift is in session. The squad room should not serve as a traffic path to other portions of the building.

Movable seating should be provided where roll-call training is conducted. The room should be acoustically treated and equipped with wall-mounted bulletin boards, chalk boards, individual mail slots for distribution of printed material, and wall-mounted clothes and hat racks. An ideal work flow pattern would show the locker room adjacent to the roll-call room.

Locker Facilities

An individual clothes locker should be provided for each uniformed officer in the department. The locker facility should be coupled with shower-room accommodations.

Training

Where possible, a training room should be separate from the roll-call room. This would allow uninterrupted training sessions. In the event that space is at a premium, the roll-call room could be designed as a multipurpose room large enough to conduct training sessions.

Library

A police library is a reflection of the philosophy of a police administrator and his agency to achieve the best possible law enforcement through constant staff study and improvement.

Savings of police budget dollars can be used to justify a professional library. It can save money on duplicate subscription costs, long-distance telephone calls, and duplication of files, space, effort, and materials. Ordering subscriptions to journals for each supervisor and administrator can be an unnecessary and excessive expense.

A library should be provided with a sufficient number of bookshelves and seating capacity to

accommodate approximately five percent of the work force. Tables in the library should be at least 5 to 6 feet from each other if the chairs are to be placed back to back. Between the tables and the walls, there should be an aisle approximately 5 feet wide. The length of the shelving should not be more than 3 feet per section.

PROPERTY ROOMS

Department Property

Department-owned property such as report forms, stationery, blank books, pencils, and other office equipment should be stored in a single room. Likewise, the department armament and munitions should be stored in a dustproof, moistureproof, secure room. It is recognized that armament must be immediately available to operational personnel; however, the supervisor in charge of property management must, of necessity, have the armament under his [her] immediate control and provide for routine inspections and inventory of such equipment. Both of these factors must be considered when planning for the location of the armory.

Evidence Room

An evidence storage room should be included in any planning for a police facility. The room should be secured against unauthorized intrusion and should allow for four different types of storage modes:

- Open bins
- File cabinets
- Safe
- Possible refrigerator

Open bins should constitute the majority of the room area. The bins should be approximately 3 feet wide and should be designed to allow for expansion upward. The balance of the evidence room can best be utilized by installing standard, letter-sized file cabinets. Small items that are more subject to loss are better stored in cabinets.

A good-sized safe should constitute the third storage mode for inclusion in an evidence room. This receptacle should be used to safeguard monies, jewelry, and other such valuables.

A refrigerator should be used to store narcotics, blood samples, and other perishables.

Since the evidence room would not normally be open 24 hours a day, it is necessary to establish temporary holding lockers into which evidence can be placed until it can be secured by the department evidence custodian. These lockers should be either self-locking or equipped with open padlocks. Officers coming into possession of evidence should properly mark it and deposit it in a locker. The door can then be snapped shut or padlocked. It should thereafter be opened only by the duly designated evidence custodian.

All evidence should be kept in the evidence storage room when not otherwise being examined or presented at trial.

LABORATORY FACILITIES

The location of the laboratory in a police building is relatively unimportant, and some advantages are gained in having it in a remote area. Space requirements and utility connections are the principal considerations; space needs are strongly influenced by the size of the laboratory staff and the equipment used. A police laboratory should be designed to meet future requirements.

Every agency should have at least a rudimentary laboratory. Depending upon the department's expertise and size, a laboratory could range in size from a single photography darkroom to a complex facility with separate rooms to accommodate: a darkroom; copy and other photographic work; chemical examinations; other laboratory instruments; evidence storage; a repository of standards for comparison; a director's office; a reception room; and a polygraph room.

Needless to say, those agencies that are physically located near a county, regional, state, or federal laboratory facility would require less laboratory space.

FIREARMS RANGE

An indoor firearms range should be considered as a very necessary component of every police facility. Such a range would most likely be situated in the basement or, in the case of only one floor, adjacent to the main facility. A minimum area for a range should be approximately 100 feet in length with a minimum of 4 feet in width for each shooting position desired.

By JOHN J. GROSFELD, AIA

GENERAL

Man is responsive to his physical environment. Traditionally, architects have relied on intuitive design processes to achieve desired responses, but recently a collaboration between architecture and the social sciences has enabled us to apply vast information resources to the problems of practical design. However, an architect seeking information finds a scarcity of scientific data about men in confinement. Until there are more studies and until collaboration becomes more general and more systematized, the correctional architect must continue to rely largely on experience and intuition.

One begins, however, with some general knowledge. Life in correctional institutions has been destructive of the human spirit; in a large proportion of cases the goal of rehabilitation has been utterly frustrated! The removal of a man from society and the attendant loss of his freedom, privacy, and independence as well as the deadeningly strict daily routine result in a totally depersonalized, totalitarian environment. Long-standing conventions in the design of correctional institutions and outmoded concepts of efficiency and functionalism have led to the repetitious and symmetrical arrangements of space and forms characteristic of the corrections field. Long corridors, highly polished floors, and hard finishes that reflect light and sound are hypnotic and result in impersonal surroundings.

The developing science of human behavior has led to an increased emphasis on the rehabilitation of offenders through treatment and academic and vocational training. Basic to these programs is a concern for the inmate as an individual. This knowledge should be applied in the design of new correctional facilities to create an environment that will foster positive responses. (See Fig. 1.)

TYPES OF FACILITIES

Increased emphasis on restructuring correctional systems to effect maximum change in offenders has resulted in the growth of various interrelated facility types, each serving different functions, often under separate jurisdictions.

Lockups

Lockups, or holding cells, are security facilities for the temporary detention of persons held for investigation or preliminary hearings following arrest. These facilities are usually operated by the police department and detention in them generally does not exceed 48 hours. Persons who must be held longer are transferred to the city or county jail.

Jails

Jails, or detention facilities, house accused persons awaiting trial and convicted offenders serving short sentences, usually a maximum of 1 year. As a rule jails are under local jurisdiction, such as the sheriff's office. Since the

Fig. 1 This correctional institution for younger offenders functions as a therapeutic community. The basic programs of the facility, namely diagnosis and treatment, are expressed by individualized building units of limited size in a nonregimented setting. (St. Albans Correctional Center, Vermont, Litchfield Grosfeld Weidner, Architects.)

inmates have not been extensively classified and the likelihood of attempted violence or escape has not been determined, security provisions in jails are at their maximum. It is entirely possible that a person brought to a jail to await trial for a misdemeanor (minor crime) might be wanted in another state for murder. This information may not be known to the jail staff until fingerprints are cleared through the FBI and other interrelated identification systems, sometimes a matter of several weeks. Traditionally, jails have not provided any rehabilitation programs because of the limited local financing and the erroneous belief that inmates spend too short a time there to benefit from a sustained treatment program. Recently, however, trends in correctional thinking and practice envision the possibility of new and more constructive uses of local jails. Through massive grants for planning and implementation, the federal government is encouraging development of extensive special rehabilitation programs directly geared to short-term incarceration. They recognize that jail represents an offender's first contact with the criminal justice system and thus it presents an optimum opportunity for intervention in a criminal career.

Jails are usually located in urban centers due to the need to be close to the courts. When site availability does not allow an adjacent court-jail relationship, a transportation system must be established to provide inmates quick and secure access to the courts.

Correctional Institutions

Correctional institutions, or prisons, are facilities for convicted persons serving sentences.

Since rehabilitation is a fundamental aim of these institutions, current correctional philosophy calls for individualized treatment to the greatest extent practical, even in maximum security institutions. Essential elements of a well-rounded individualized correctional program include scientific classification and program planning based on complete case histories and examinations, medical and dental services providing corrective as well as curative treatment, individual and group therapy and counseling, academic and vocational training, indoor and outdoor recreation, casework services for prisoners and their families, and preparation for parole or release.

The variety of treatment programs which correspond to the different needs of offenders require a system of specialized correctional institutions so classified, coordinated, and organized in staff and program as to meet the specific needs of offenders.

Some correctional institutions are under local control, such as a city or county penitentiary or workhouse, but the majority are under the jurisdiction of a state department of correction. Traditionally, such institutions have been located outside the urban centers isolated on large tracts of state-owned land. These self-sustaining communities have a complete complement of personnel and services, including medical, educational, recreational, religious, food and maintenance services. The trend toward isolating the correctional institution from the community is slowly being reversed because of an increased awareness of the need to involve the community in the correctional process and because of the rising costs of providing services in an institution which already exist in the community.

JAILS AND PRISONS

Community Correctional Centers

Community correctional centers are the result of the new emphasis in correctional theory to build or rebuild solid ties between the offender and the community, to integrate or reintegrate the offender into community life. This type of facility is located within the community and can serve to contain both pretrial and sentenced offenders.

The basic premise of such a facility is maximum utilization of community resources in the correctional process by providing existing services to the facility on a contract basis. For example, the educational and commercial-industrial resources of the community can be utilized for the training and rehabilitation of offenders. Thus the community correctional center can function as an outpatient clinic, providing a treatment center for an expanded probation and parole system, and ultimately relieving the overcrowded conditions in the existing penal institutions.

THE PLANNING TEAM

Planning for detention facilities involves many individuals at governmental and local community levels. Since no single planner or organization can adequately consider all the needs of the community in planning a detention facility, the architect's role during this early stage must be as a member of a specialized team.

In large metropolitan jurisdictions, a professional planning agency initially projects the detention facilities, integrating the scheme with broad-scale plans for community develop-

ment. Close collaboration with the administrations of the principal agencies involved, such as law enforcement, judicial, corrections, probation and parole, is mandatory. Also, a citizens' advisory committee may be formed, consisting of competent and concerned community members, whose support can be crucial in community acceptance of the new detention facility.

Since smaller communities have more limited technical or professional resources, the planning responsibility may be assigned to a group of local administrators, a local crime commission, or a citizens' council. In such instances, an architect knowledgeable in correctional facilities design can play a major role in the planning stage, coordinating all the available resources.

DEVELOPING PLANNING INFORMATION

Of utmost importance in planning a detention facility is a clear idea of the ends to be served and the means of achieving these ends.

The steps involved in initial planning for a new detention facility consist of a process of outlining a series of priorities of needed improvements based on a number of assessments which are supported by as much firm data as may be available. These basic steps are discussed below.

Assessment of Needs

Basic to the planning of a new facility is an analysis of the numbers and types of persons to be served. This task is made more difficult

by the need to consider the various areas that peripherally affect the field of law enforcement and determine increases or decreases in inmate population. For example, the initiation of an effective bail reform program will significantly reduce the number of persons held in pretrial detention. Acting in reverse, any substantial increase in the number of accused persons accepting their right to legal counsel and choosing their right to a jury trial will increase court operation costs and extend jail time from arrest to final disposition. A marked increase in law enforcement effectiveness can result in more arrests and an increase in jail population. A judicial reform program that initiates measures as a substitute for pretrial detention, such as issuing of summons or release on recognizance with promise to appear in court, will substantially reduce jail populations. The planners need to consider all these programs and anticipate their effect on the projected inmate population.

Inmate population projections consist primarily of estimates of the numbers and kinds of people coming into the correctional system. Information must be broken down by age, sex, offense, and tendency toward rehabilitation. This task may be most difficult if the statistical data available to the planners are not broken down in specific categories. The following is a partial list of the type of information needed for planning:

1. Number and dates of arrests by major categories
 - a. *Felony crimes.* Breakdown by crimes against property, against persons, against public order; narcotics and drug sale and use, and sex

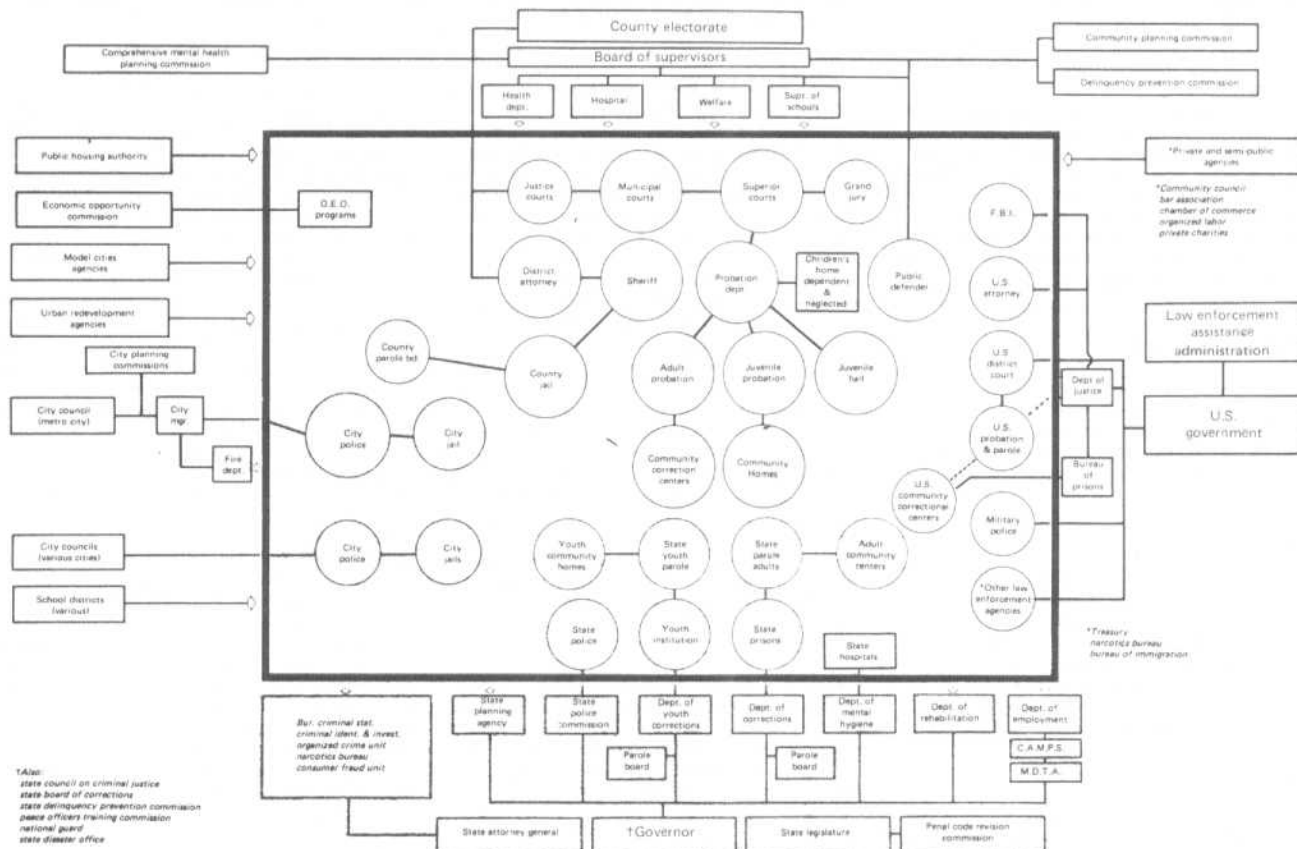

Fig. 2 Jurisdictional structure of a criminal justice operation at the community level within a typical county government boundary. (U.S. Bureau of Prisons.)

- b. *Misdemeanor crimes.* Same breakdown as for felonies. Separate alcohol-involved arrests and minor traffic arrests
2. Number and dates of judicial actions
 - a. *Adjudication actions.* Number dismissed, transfers to other jurisdictions, pleas as charged, pleas to reduce charges, to trial, convictions
 - b. *Sentencing actions.* Numbers of
 - Fines, restitution orders and suspended sentences
 - Jail sentences
 - Probations granted
 - Prison and reformatory sentences
 - Commitments to community correctional centers
3. Number and movements of sentenced offenders by
 - a. Time served in jail before discharge
 - b. Time served in state institutions before parole or discharge
 - c. Time served on probation before discharge
 - d. Time served on parole before discharge

Analysis of Existing Systems

To plan a new facility, a clear understanding of the function of the existing criminal justice system is essential. Basic analyses should be made of the flow of offenders through the system, specific functions of the system, and costs incurred.

Figure 2, a schematic diagram, represents all the criminal justice activities which may be found at the county level, as well as the various organizations and agencies that provide programs and services for these activities. This configuration will not be applicable to all localities. By formulating such a chart for a particular local governmental jurisdiction, planners will see where duplicate and overlapping functions occur within the existing system, enabling them to restructure these areas.

Figure 3 is a schematic flow chart showing the various stages and directions an offender moves through from arrest to release. The complete comprehension of the offender flow for a particular jurisdiction is critical in order to make the flow more efficient, especially at points where decisions are made. Vital statistics, such as the number of offenders involved in each step of the process and the average time for completion of each step, must be included in the chart.

The analysis of cost-effectiveness of correctional programs and facilities will involve looking at the entire correctional process of a particular system. Capital required for a new facility, cost of construction, and operating cost per inmate can be estimated with some degree of accuracy. The effect on the overall corrections system should also be weighed to fully justify the new facility, using data on the costs of community-based services, probation and parole. Projected costs can then be compiled to show the anticipated effect of the system and its new facility on the crime rate of the community. These projections of cost effectiveness of criminal career intervention should be compared with the costs likely to be borne by the community if the offender were to continue his criminal career.

Identification of Resources

Before planners can consider what new programs or facilities should be introduced or expanded, they must clearly identify the types and amounts of support that presently may be

available from all sources. Some of these sources may be outside the jurisdiction of the correctional system, such as certain governmental agencies or private agencies and organizations. Services may exist within the community such as paraprofessional volunteer help. Identification of these existing resources involves exploration of legislative groups, governmental agencies in the field of education, health, mental health, social welfare, employment services, and vocational rehabilitation as well as industry, labor, and civic groups.

The resulting inventory or resources then can be evaluated in the light of the professed goals of the correctional system to determine the new resources needed to attain these goals and the steps needed to tap new resources.

The resulting tabulation of existing and new resources will then provide the operative framework for the proposed new facility.

Analysis of Funding

After the correctional programs, services, and new facilities have been defined, the task of estimating basic costs of implementation and the identification of funding sources remains. Included in this analysis must be investigation of other agencies that contribute services or personnel. The sequence, timing, and amount of funds needed and the basic components of an operating model require delineation. A plan for the establishment of a new correctional facility will not start immediately as a full-scale operation but will be implemented gradually, involving construction of the physical plant, setting up of new correctional programs, hiring and training of staff, and finally, occupancy and program implementation.

Basic sources for funding are local government capital budgets and state or federal subsidy programs. Most funding programs combine several sources, devising intricate formulas for matching funds and allocating subsidies to specified programs. Guidelines for governmental subsidies vary from year to year and therefore need to be continually evaluated for applicability. Applications for subsidies should be filed as early as possible during the initial planning stage, since the bureaucratic process delays the date of ultimate approval.

Planners who inform themselves about the specific programs of existing subsidies can structure their new programs and facilities to take optimum advantage of available assistance programs. For example, if the federal government desires to promote the development of community-based correctional facilities that utilize maximum existing community resources, then perhaps a proposal from a local government to establish such a facility as a model project will receive maximum federal funding assistance under the "Discretionary Grants" section of the federal subsidy program. Funding assistance is available for every phase of criminal justice development, including planning, construction, staffing, and operation of new facilities.

Systems for Implementation

Another early planning function is determination of the systems and administrative machinery required to implement the new program. There may be an ongoing system which will absorb the new program with a minimum of expansion or change. More likely, however, it will be necessary to establish an administrative body carefully allied to supportive agencies (parole, employment, etc.) to ensure

the most effective delivery of programs and services. This procedure can involve decisions on shared responsibilities, which may require new enabling legislation. By categorically identifying the range of proposed programs

Fig. 3 Typical offender flow through the criminal justice system.

JAILS AND PRISONS

and services, planners are in a position to effectively mold the administrative system's needs into a comprehensive whole.

Planning for the Future

Comprehensive criminal justice planning is concerned with present and future effectiveness of the overall system. Budget allowances often limit the progressive development of programs and facilities, but the establishment of master plan timetables can accomplish the required improvements within the limitations and within a realistic schedule. Planning for future capacities will enable architects to allow for orderly expansion of facilities with a minimum interruption of the ongoing facility. As new methods of treatment are developed, the programs change and therefore maximum flexibility is required. By establishing a clear program of development, necessary preparatory steps may be taken well in advance to facilitate transition into future stages.

SITE SELECTION

Numerous factors must be considered in the selection of a site. Initially, the geographical area for the new facility is determined by the source of the majority of inmates to be served, although many other factors are important. Within a geographical area the factors to be considered in site selection are as follows. (See Fig. 4.)

Availability of Resources

In relation to maximum program effectiveness, the facility should be as close to the centers of business, industry, schools, medical facilities, welfare service agencies, and the courts as possible, and accessible to public transportation. Close proximity to a major college or university is highly desirable, in order to encourage development of a curriculum in law enforcement, using the facility as a teaching laboratory. Consideration should be given to community areas that could supply staff personnel, although an innovative and rehabilitation-oriented facility will attract high-caliber staff anyway. Accessibility to major industries and business facilities is essential for a successful work-release program.

Land Costs

Unless a facility is to be very small, the site cost will represent a very small percentage of the total cost of the completed facility. A mediocre or poor site should not be selected just because the saving might be 50 percent greater than that of a good site. This type of economy might be very expensive in the long run. For example, the initial capital outlay for an inner-city facility undoubtedly would be substantially greater than in an outlying area because building sites are scarce, expensive, and affected by zoning ordinances. Construction costs for an inner-city facility would be more expensive, requiring vertical high-rise development to achieve the required separation of functions. Against these factors must be weighed the increased operating costs of an outlying site: longer transportation time and additional man-days for inmate escort duty.

Topography and Utilities

The site should be reasonably level with sufficient slope to provide good drainage. Ample

acreage is required for the physical plant and its roads, parking, and recreation areas. A "buffer zone" of vacant land is desirable to avoid encroachment of private construction to a point where it would influence the free flow of inmates within the facility. Studies should be conducted by professionals to determine subsoil conditions, water supply, and availability of all major utilities.

Access to Community

Family visiting can play a major role in reorienting an inmate's antisocial attitude and alleviating bitterness and despair over his imprisonment. Therefore, the facility ought to be within easy reach of the communities served. Also, utilizing a new and relatively untapped resource—the community volunteer—requires ready access to community areas.

Acceptance by Community

This consideration is of major importance to the ultimate success of a new facility. The community must be receptive to the establishment of a new correctional institution in its midst. This is a most sensitive area for many citizens, and a well-planned and early campaign of public relations and information dissemination will pay high dividends in community acceptance. Meetings should be scheduled during the initial planning, with local community leaders invited to speak and to explain the function of the proposed facility to the townspeople. Alienation toward prisoners can be overcome by developing interests in an active volunteer program that cultivates advocates for the facility within the community.

DESIGN PRINCIPLES

Basic to the development of design principles related to correctional architecture is the criminal justice system as it has existed in the past, as it exists today, and as it will exist in the future. Present and future in particular must be considered by correctional planners as the framework for the design of innovative models for correctional management.

Historical Background

The development of corrections theory in the United States can be traced from the early

nineteenth century, where punishment and restraint were the major components of the criminal justice system. Gradually penologists became aware of the need to rehabilitate prisoners, but early attempts to do so called for encouraging offenders to contemplate their sins in solitude and silence. This method only replaced physical maiming of prisoners with a psychological maiming which is potentially more destructive.

By 1870 some concerned penologists recognized that the methods employed to rehabilitate offenders were not working. They drew up a Declaration of Principles adopted at the first meeting of the American Correctional Association in Cincinnati. It included the following objectives:

- * Reformation, not vindictive suffering, should be the purpose of penal treatment.
- * The prisoner should be made to realize that his destiny was in his own hands.
- * Prison discipline should be such as to gain the will of the prisoner and conserve his self-respect.
- * The aim of the prison should be to make industrious free men rather than orderly and obedient prisoners.
- * Prisons should be small, and separate institutions should be constructed for different types of offenders.
- * There should be established a system for the collection of uniform penal statistics.
- * Society at large should be made to realize its responsibility for crime conditions.

(The reader who is unfamiliar with the history of corrections will be interested to know that in 1970 The American Correctional Association met in Cincinnati and found the same faults existing today and reiterated the same recommendations.)

With the coming of the reformatory era, corrections evolved its own identity as a profession by emphasizing vocational training and education, followed by individual casework. Crime came to be seen as a symptom of sickness. Group therapy and counseling, the therapeutic community approach, and community-based treatment are the current dominant correctional concepts, but punishment and revenge have remained a basic part of the correctional structure.

Security Grading

The stated goals of today's correctional system include the protection of society, deterrence

Fig. 4 Major elements in site selection for a detention facility.

of crime, and rehabilitation of prisoners. Most penologists acknowledge that the majority of offenders in our correctional system do not represent a repeated threat to society. Due to the lack of a reliable means of determining risk potential, a majority of offenders are imprisoned without necessity.

Although the emphasis placed on rehabilitation of offenders seems to meet with society's approval, correctional administrators are generally inhibited in innovative measures because of a lack of valid information about public attitudes. An escape or a crime committed by a probationer is met with outrage and indignation by the public, providing correctional administrators only with the most negative public opinions upon which to base decisions. Only too often the response to innovation is "the public isn't ready for that," when the administrator has no positive means of assessing public readiness.

Ideally, a correctional system should include several types of institutions offering varying degrees of custody and types of treatment programs. The following describes the three basic types of specialized institutions.

Minimum Security Sometimes referred to as the open institution, this facility operates without armed guard posts. If it has a fence at all, it is only for the purpose of keeping the unauthorized public out.

The inmate housing facilities of a minimum-security institution may be comprised to a large extent of open dormitories, which are by far the most economical type of housing facility. Individual rooms, however, are preferable to dormitories for a sense of privacy not readily available in a regimented institutionalized setting. The ideal housing situation would be single rooms that allow inmates to lock their own rooms but which are accessible to the staff by master key. Dormitories are particularly unsatisfactory as housing in women's institutions, based on our society's traditional standard of modesty and privacy for women. Regardless of whether dormitories or individual rooms are selected, planning must provide easy supervision of the inmates' quarters.

The open institution is certain to play an increasingly important role in future correctional systems. The term originated with an emphasis on young offenders or prisoners nearing release date, but it currently covers a broad range of facilities having in common only the absence of barred windows and armed guards. These would include open camps or farms adjacent to security prisons that operate as satellite facilities, or separate independent camps for reforestation, land reclamation, or farming. An idea as yet unexplored is the open camp related to urban industrial activity.

Medium Security Custody in a medium-security institution is generally achieved by a perimeter control system that allows considerable free movement within the facility. Perimeter control consists of two lines of fencing 12 to 15 ft high separated by a space of at least 20 ft. Varying degrees of surveillance techniques, ranging from staff patrol to electronic detection systems or both, keep the perimeter fence under scrutiny. Perimeter control can be extended to include the exterior skins of housing units. In this manner, control is effected by the exterior walls, windows, doors, openings, and roof construction, while still allowing relatively free inmate movement inside.

Inmate housing in a medium-security institution should consist of individual outside cells, rooms, or dormitories. Dormitory housing always remains a compromise between

PRETRIAL DETENTION

CORRECTIONAL INSTITUTIONS

Fig. 5 This diagram shows approximate proportions of security grading of inmate populations in multicustody detention and sentenced facilities.

construction costs and the more ideal arrangement of individual rooms or cells, since rooms or cells with exterior windows provide inmates with a sense of individuality and territory.

Maximum Security Emphasis in this type of facility is on control and supervision via a perimeter fence or wall system in housing units and in all building areas accessible to inmates. Perimeter control is often effected by strategically located towers containing armed guards or by circulating patrol cars in constant contact with the control center which monitors an electronic intrusion-sensing system along the perimeter enclosure.

Housing facilities in maximum-security institutions are characterized by individual cells with their own plumbing and sanitary facilities. A small percentage of the housing may be composed of interior cellblocks consisting of groups of cells not directly accessible to outside walls or windows. Planning must consider maximum staff surveillance of all inmate areas

and activities, with cells readily observable by staff.

This degree of custody is required for less than 15 percent of the total inmate population in a correctional system.

Multisecurity While ideally it is desirable to provide separate institutions for each type of security system, such compartmentalization is available only to correctional systems with a high inmate population. For the smaller systems, such as those of counties, cities, or low-density states, it is unlikely that funds will be available for separate facilities. In these instances, a single institution will house the total inmate population of the system. Maximum separation is needed between custody groups to avoid inhibiting the full participation in the correctional program of minimum-security inmates due to restrictions imposed on inmates under maximum custody.

It is impossible to prescribe a formula for determining proportions of maximum-, me-

JAILS AND PRISONS

dium-, or minimum-security offenders that apply to all correctional projects. This proportion must be determined at the initial planning stage and should consider the effectiveness of services and programs that provide diversion from incarceration, such as bail practices, release on recognizance, probation, parole, and extra-agency referrals. It is certain that a system that does not incarcerate low-security risk persons awaiting trial will require a higher proportion of maximum- and medium-security facilities in its jail. Likewise, a system that does not have a strong probation and parole system will require a higher proportion of minimum-security facilities.

Figure 5 lists suggested proportions of basic security types to be provided in a multisecurity facility. These proportions are a general guide only and are given here to provide a basis for the planning described above.

Physical Image

A structure communicates its identity and goals to its users and to the community through its physical appearance. The attitudes of community residents toward the corrections system will be influenced by what they perceive as the physical image. In the past, the character of correctional buildings was expressed by a monolithic, fortresslike, and generally forbidding appearance.

The basic design of correctional architecture should clearly identify the function and purpose of the facility. The need for a variety of external controls, such as fences, locks, and detention windows, still remains. But these external controls need not be the dominant theme of the perceived environment, since the avowed purpose and goal of modern corrections are to build up the offenders' internal control over their own behavior. Because social controls replace external controls to a large extent, external controls where required should be subtly and unobtrusively integrated into the building form. The type of external controls recommended are the minimum consistent with the goals and methods of the correctional program.

Building Massing

After determining the correctional program, planners need to consider what basic form a new correctional facility will take. Certainly the character of the site plays a dominant role: an urban site limited in area will undoubtedly require vertical stacking of functions. This arrangement will apply particularly to urban jails that need to be easily accessible to the

courts. The resulting jail requires an efficient vertical transportation system for both inmates and staff. Major problems confronting the planner involve communication between inmates and pedestrians, vehicular traffic to and from the facility, and the provision and furnishing of outdoor recreation areas. (See Figs. 6 and 7.)

Where larger tracts of land are available, horizontal arrangement of functions will allow a more flexible expression of the program. A connected plan lends itself well to high-custody facilities where maximum control of inmate movement is required, while the multi-unit plan permits a greater freedom of movement between units, with basic control provided by the perimeter enclosure.

Size of Facility

The size of a new facility should be determined from estimates of the rate of commitment of inmates and their length of stay. The absence of uniform data makes this assessment a most difficult and uncertain task.

The maximum inmate population for a correctional facility should not exceed 500. Any institution operating as a single unit becomes increasingly inefficient and unsafe when its population exceeds that number. An ideal population should not exceed 200. There are institutions with capacities of 5,000 or more because the practicalities of state government make it easier to obtain funds to add to an existing institution in a piecemeal fashion than to acquire a new site and build a completely new facility. An analysis of operating costs often indicates that a high capacity means lower per capita costs. Such figures are easily computed and readily understood by legislators and the lay public, but the negative effects of large overcrowded institutions are clear only to the prison administrator.

All authorities involved in corrections and in the science of human behavior agree that a maximum homogeneous population of 200 offers the best milieu for treatment. The larger the institution population, the more its inmates and staff lose their identity and individuality. Conversely, the per capita cost of operating a fully programmed institution that is too small would be prohibitive. It is obvious that a compromise must be reached between the ideal treatment population and the funding capacity of the system.

A viable compromise is the satellite concept of planning. This approach involves the breaking up of a large institution into several smaller units, but still operating as a single administrative unit. Such a facility potentially has the

economy and program range of the large institution, yet retains the personalized treatment and safety valves inherent to the smaller facility.

Flexibility

Not only are the types of prisoners and purposes of their confinement undergoing constant change, but also the methods used to deal with them. New techniques, programs, and services present new requirements, necessitating the capability of self-modification through feedback and evaluation. Modification must also be aided by the physical design of the facility for this evaluation to be effective. Design for a number of indeterminate future conditions rather than a single set of fixed functions implies a "loose fit" between form and function at any point in time. It is far more desirable to have a facility with some "float" space than a building that fits today's needs so tightly that it becomes obsolete immediately when programs begin to develop and change.

In addition to responding to their own internal expansion needs, correctional facilities serve as a catalyst for the location of other nearby public and private community services. For example, a single unit could grow into a community resources mall, in effect an administrative subcenter of county-state-city social services, justice, and other governmental functions (see Fig. 8).

The degree of flexibility in spatial arrangement and convertibility of space that can be realized is determined by:

- The location of fixed circulation elements, such as stairs, elevators, and entrances
- The location of fixed service elements and utilities
- The structural module, including spans and location of fixed elements such as columns
- The design of mechanical, distribution, and lighting systems
- The design of flexible systems of partitions and interior finishes

The creation of flexible spaces requires early decisions in the design process about the extent and degree of flexibility required. All component building systems, especially the structural and environmental control systems, need to be organized into a pattern to allow maximum flexibility. Considerations of economy and performance ought to be made in conjunction with the degree of flexibility desired, for example, comparing a totally flexible, movable wall system with a semiflexible system of nonbearing partitions constructed of permanent materials. The movable system would initially be the more expensive, but frequent plan revisions in the semiflexible system would more than use up any savings initially gained by its selection. Noneconomic factors, such as use appropriateness (sound control, security, resistance to use and abuse) must also be taken into account.

Circulation and Security Control

The movement of inmates and staff within a correctional facility is a problem of major dimensions. Due to the complex functions, circulation from living quarters to dining halls, to work assignments, to school, to recreation, to infirmary, to canteen, to the administration building, and to numerous other parts of the institution needs to be planned not only to provide easy flow, but also to allow required supervision and custody control. The problem of supervision and circulation is just as important to the movement of supplies and materials throughout the institution.

Fig. 6 Vertical massing is a response to limitations imposed by an urban site.

Fig. 7 Horizontal development as indicated by two different concepts unrestrained by site limitations but expressing distinct levels of custody through massing.

Security in a correctional setting can be obtained in numerous ways: by technological advances in electronics, such as audio- and visual-monitoring systems; by more effective interpersonal relationships between staff and inmates; by more effective inmate diagnosis and classification; and by providing achievement-oriented correctional programs.

Basic security control can be attained in either of two ways. Primary reliance can be placed on a strong perimeter security system, with armed towers and sophisticated fence alarm systems. This method permits the inner compound area to be fairly open and allows greater freedom of movement within. Relatively little security is provided by internal structures. Conversely, reliance can be placed on the internal structural security of the facility's units themselves. This approach promotes minimal controlled movement between units and, therefore, there is less of a need for a strong perimeter security, but inmate participation in the correctional program is generally limited to that which can occur within the respective units.

Neither of these extremes is wholly appropriate for most institutions. The process of zone control more closely approximates in structure and operation the varied security needs of diverse programs and services. There are facilities that operate around the clock

and, therefore, require the greatest security and supervision, such as housing units, infirmary, control center, and main entrance. However, some facilities, such as the dining hall, may operate from 12 to 16 hours a day, others will operate 8 hours a day for 5 days during the week, while still other activities will occur for only 3 or 4 hours during the evening. By grouping the facilities in accordance with the schedule of use and by carefully planning access to these areas, portions of the institution not in use during certain periods may be closed off entirely to the inmate population, thus reducing the need for custodial control.

BASIC ELEMENTS OF A CORRECTIONAL FACILITY

Housing

The choice of inmate housing type is directly related to several factors: the type of facility planned, what programs, staff, and funding, both for construction and for operation, will be available. There are few guidelines regarding the ratio of cells to dormitory space. The guidelines that do exist often conflict, depending on the balance of priorities between maintaining security, providing an effective rehabilitative environment, or having an adequate professional staff. Planners will find that it is impossible to satisfy fully all these criteria.

Individual cells are advisable for institutions handling maximum-security inmates who require constant supervision. Inmates who are not maximum-security risks and are allowed more freedom of unrestricted movement in the housing units can be housed in individual rooms or in dormitories. Since jails and detention centers confine inmates whose requirements for supervision and control are virtually unknown upon arrival, a fairly high proportion of single cells or rooms is advisable, while open institutions and minimum-security camps can have a higher proportion of dormitory space (see Figs. 9 to 15).

One of the factors that influences the ratio of cells to dormitory space is the extent to which the institution has the staff and facilities to gather information essential for inmate classification. Since the total inmate treatment and training program is conditioned largely by custody requirements, its success is almost wholly dependent on flexibility of custody classification and handling of prisoners. When such basic data about offenders is available, management of the inmate population is made easier, and housing assignments can reflect the actual security problems which individual offenders present.

Interior Cells These are usually placed back-to-back in the center of the cellblock with a continuous utility space separating the two rows of cells. The utility space provides a means of running plumbing, ventilation, and electrical utilities in an area accessible for easy maintenance. Plumbing fixtures are fitted into the rear cell wall that defines the utility space. The piping extends directly into the chase, with tamper-proof pushbutton valves the only item exposed within the cell. Wall-mounted water closets are preferable to facilitate cleaning of the floor, but where fixtures may be damaged through abusive use, floor-mounted units should be installed. Mild-steel grilles along the front of the cell admit light and air, while allowing for maximum supervision of the occupant. Continuous fresh air should be provided by mechanical ventilation through the front of the cell and exhausted through registers in the back wall of the cell. It is expedient to firmly anchor steel beds and desks to floors and walls. Cell walls may be constructed of mild steel plate $\frac{1}{4}$ in. thick, with vertical splice joints every 3 ft, or of concrete or masonry blocks. Steel plate is often more economical, requiring less space than concrete or masonry and reducing the cell-block length. Masonry is preferable for noise control since its semi-absorbent surface is able to reduce the high level of background noise, a characteristic of multiple steel cells.

Fig. 8 Flexibility must allow for growth in response to program changes in the future.

Governmental and Public

JAILS AND PRISONS

Fig. 12 Low internal security. Personal spaces with potential for individual inside locking. Central group space for informal or structured activity. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

Fig. 13 Medium internal security. Seven rooms at upper level, seven at lower; group space and entry at middle level, providing separation of private space from group space with staff supervision of movements. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

Exterior Cells These are located on the outside wall of a housing unit, each with a window. A traditional arrangement consists of two rows of cells with a central corridor, but new imaginative planning concepts are breaking out of this mold by grouping cells around common activity spaces or arranging them along single-loaded corridors. Sliding or swinging doors open into the cell and are fitted with vision ports for nighttime bed checks. Toilet fixtures are attached to individual pipe chases, back-to-back for two cells, with access for maintenance. Furniture may be built-in or movable, depending on the degree of security required. Ventilating air, introduced into the center corridor, is drawn into the cells through door undercuts and exhausted through a register in the pipe chase. Walls are of concrete or masonry units; floors are concrete with a steel-troweled finish. Cells may be provided with radio speakers broadcasting programs from a central station with a limited selection of stations.

Inmate Rooms These are individual living spaces that resemble college students' rooms. Furniture is movable; toilet fixtures are centrally located for common use by the members of the housing group. Swinging doors can be wood or hollow metal, and the room occupants may have a key that controls the door lock, although there is provision for an overriding custodial deadlock. Rooms have outside windows with sashes of varying degrees of security. Radio hookups should be provided as well as an electrical outlet for use of an electric shaver. Wall and floor surfaces ought to be selected for durability and ease of maintenance, but with a concern for livability.

Dormitories or Squad Rooms These should be planned for ease of visual supervision, avoiding, for example, double-deck beds because of blind spots created by the high units. Each inmate usually has a locker for his belongings, which can be an integral part of his bed or located in a bank of lockers. Beds are best

Fig. 14 High security. Cluster component arranged for close staff surveillance of functions by direct observation. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

arranged in informal groupings that permit circulation and avoid a rigid grid pattern. A floor area of 55 sq ft for each bed and its circulation space is recommended. Maximum densities of dormitories should not exceed 30 persons in a single group, and 20 persons is even better. In order to provide a more livable environment for each inmate and offer him some privacy, lightweight panels can be erected to form cubicles around bed areas. Although this arrangement makes supervision less easy, this problem can be solved easily by orienting the open ends of cubicles towards the control area. Chairs and tables ought to be provided in dormitory areas particularly if there is not an adjacent dayroom.

Housing Support Functions

In addition to the raw housing space required for inmates' sleeping accommodations, certain housing support functions are needed for the operation of the unit. Each housing group should have a casual recreation area, generally called a dayroom, adjacent to the living quarters. Dayrooms should allot a minimum of 15 sq ft of space per inmate and should contain a large closet for equipment storage. Activities that might take place in the dayroom are casual games (cards, dominoes), ping-pong, television watching, reading, and dining (as opposed to central dining). Separation of areas by noisy and quiet activities is highly desirable.

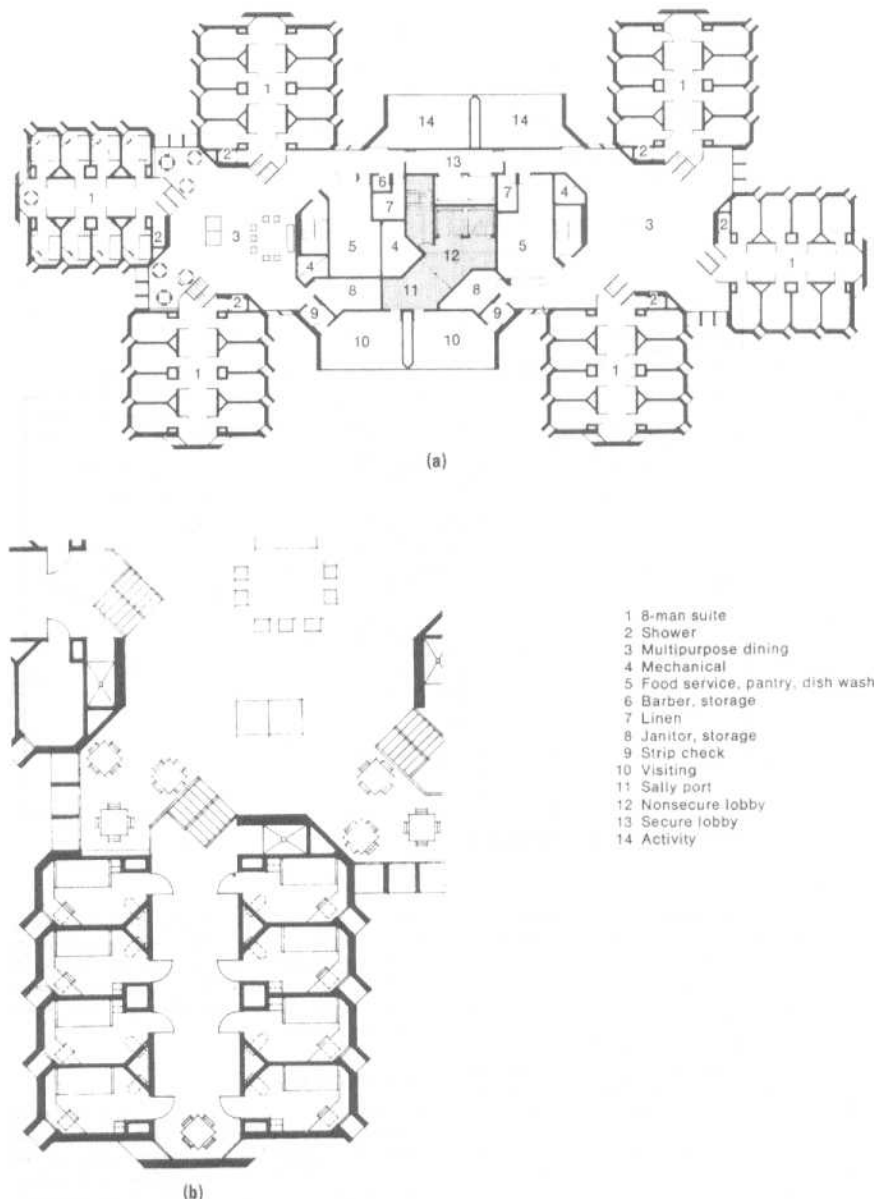

Fig. 15 Small group living expressed by this design for a metropolitan correctional center. Each floor provides a full range of program activities. (a) Typical living unit floor plan. (b) Typical 8-man suite. (Federal Correctional Center, New York City, Gruzen & Partners, Architects.)

Utility functions to support a housing unit include group toilets (except for cells which have individual fixtures), showers, and a janitor's sink. In addition to these basic functions, housing units may require closet space for storage of clean and soiled linen and clothing, depending on the institution's method of distributing such articles.

It is recommended to provide small laundry facilities near housing units utilizing commercial machines so that inmates can do their own personal clothing, particularly in a detention center where an institutional clothing system may not exist.

ADMINISTRATION

An essential first step in the planning of administrative functions for a correctional facility is

to determine the organizational pattern of authority. The agency having jurisdiction over the facility establishes the pattern, generally without the participation of the planners, although it will form the basis for space planning.

Administrative functions can be grouped to include those facilities that are located outside of security controls of the institution, and those within the basic security system. Functions to be located outside of security are those in which the staff needs to be accessible to the public and requires ease of ingress to and egress from the institution. Such functions include those of the office of the head of the institution, the business manager, certain deputy wardens whose duties relate to the public, and their various administrative, clerical, and secretarial staffs.

Those administrative officers whose work relates directly to the inmate population should

have their offices within the basic security system of the institution, preferably near the most vital area of his function. The deputy warden in charge of custody would, for example, have his office adjacent to the central control room and the key control points of the institution. The deputy warden in charge of the inmate program ought to be located in the heart of the institution so that he is not isolated from the inmate population that he serves. Similarly, administrative officers such as directors of education, recreation, and vocational training should have their offices located within the operating areas of their programs.

An idea gaining acceptance is the inclusion of arraignment court facilities within a detention facility. With a courtroom directly within the portion of the institution under security, the elaborate precautions involved in guarding prisoners and transporting them to the courts is unnecessary. The judge and attorneys come to the jail instead. There are problems created by admitting judges and attorneys within the controlled zones of the institution, but these are minor compared to the difficulties involved in transporting prisoners to the courts.

CORRECTIONAL PROGRAM

Program functions include all areas of activity which involve the professional treatment of inmates to influence change in attitudes and behavior. Some basic program functions in a correctional institution are:

- Counseling
- Casework
- Clinical services
- Education
- Vocational training
- Work-release or study-release

Counseling

Counseling is the establishment of a direct relationship, either at a personal or group level, in an attempt to solve specific personal problems or develop over a period of time increased self-understanding and maturity. Counseling may be the natural outgrowth of personal relationships between staff and inmates developing through day-to-day contact or the deliberate structuring of groups for mutual discussion of inmate and staff problems. Arranging living accommodations in small groups provides a natural setting for the development of counseling relationships between custodial staff and inmates. Optimum size of the counseling group seems to be from 8 to 12 persons, and a multi-use space within the housing unit where such activity can take place on a scheduled basis is highly desirable. Each housing unit should also include office space which can be utilized for individual interviews and private discussions.

Casework

Casework comprises services by professionally trained personnel (study, diagnosis, and treatment of psychosocial problems) administered individually or on a group basis. Casework activity involves obtaining the inmate's social history, solving immediate problems with family or other persons, exploring problems of social adjustment, and providing supportive guidance and information for release. In addition to the general institution program, other situations aided by casework services are presentence investigations of

Governmental and Public

JAILS AND PRISONS

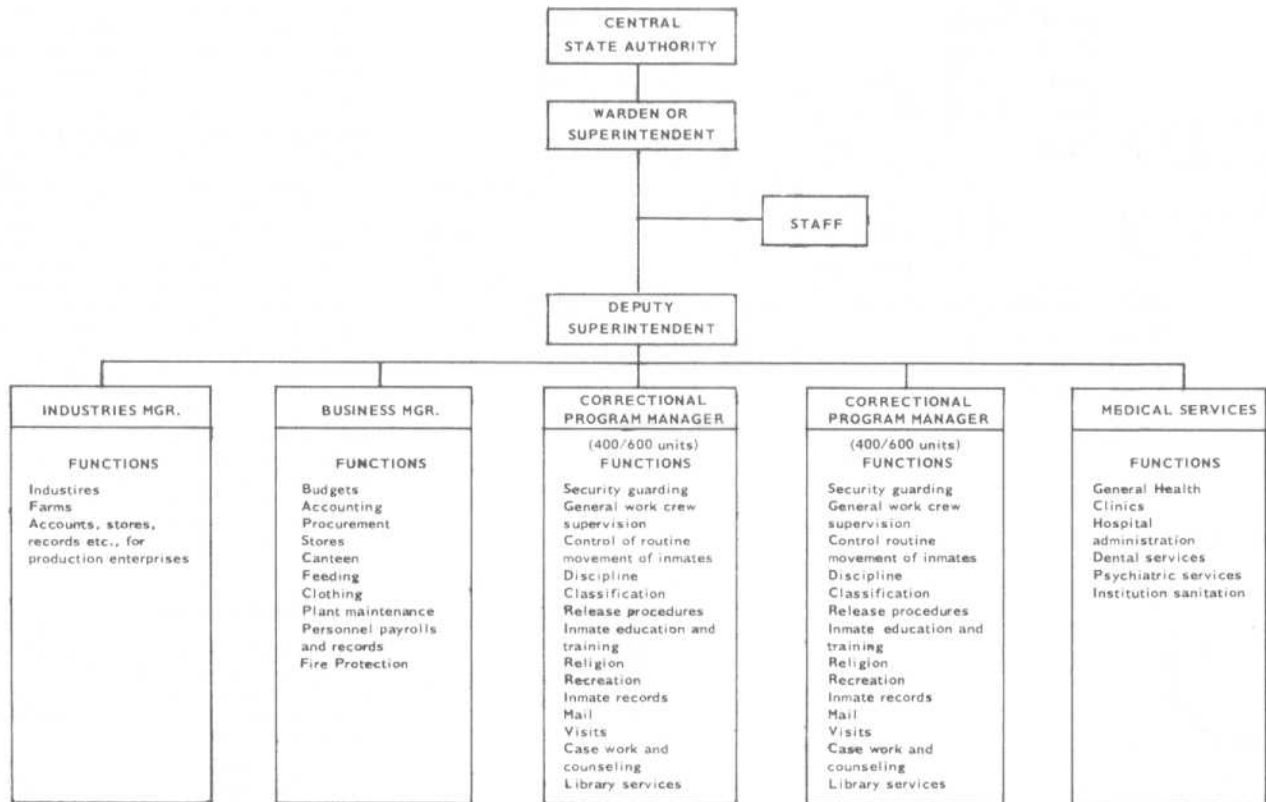

Fig. 16 A suggested organizational framework for a correctional institution with a diverse rehabilitation program.

detainees (for probation), the reception process, and postinstitutional supervision (parole). Casework activities are most effectively carried out in a centralized area that has ready access to typing services and records, although it is possible that a caseworker might go to see his client in an interview room in a housing unit.

Clinical Services

Clinical services rely on a professional staff such as psychiatrists, clinical psychologists, psychiatric nurses, occupational therapists, and other specifically trained technicians. These services provide intensive diagnostic and treatment techniques to discover causes and cures for individual maladjustments. The clinical staff also provides guidance and support to other staff members to aid them in their custodial responsibilities, including conducting sessions on personality theory and psychodynamics for line personnel. Allowances should be made in the maximum-security unit of the institution for individual and group treatment by the clinical services personnel. The general inmate population could go to a centrally located clinic.

Education

Education in prison is basic to any comprehensive correctional program. From 10 to 30 percent of all prison inmates are functional illiterates with an inability to surpass minimum test scores for the fourth grade. Only 1 to 3 percent have completed high school. Statistically, retardation in educational achievement is highly correlated with the extent of criminal behavior. While the median school level

attained by the United States population as a whole exceeds the tenth grade, prison inmates have a median of eighth grade. This is a clear indication that inmates would be better prepared for today's job market and for the other responsibilities of a noncriminal life if they had more education (see Figs. 16 to 18).

Design standards for educational facilities in prisons are the same as for other schools, with perhaps more emphasis on flexibility, such as interior partitions that can be moved as the curriculum changes. A basic correctional education program should provide for the following subjects:

- Academic
- General education
- Institution orientation
- Prerelease instruction
- Commercial training
- Music
- Health education
- Arts and crafts
- Dramatics
- Audio-visual room

The educational unit should be located on a major circulation corridor for maximum accessibility to inmates. Many classes will be taught in the evening by the extension service of a state university or by a teacher from a nearby college. It must be possible to use the educational unit during these hours without undue traffic through areas that are normally open during the daytime only. A close connection should exist between the educational unit and the library. It is wise to make the audio-visual room adaptable for a range of uses, with ample ancillary storage space for additional chairs and musical instruments. The music room, of course, must be situated for minimum inter-

ference with classroom areas. Adequate space ought to be set aside for the education director and staff. Toilets for inmates and staff need to be provided within the unit to minimize unnecessary movement through the main entrance to the unit.

Vocational Training

Vocational training programs in prisons have to extend beyond those operations which are necessary solely for the maintenance of the institution and prison industries. In addition, the inmates' level of educational achievement needs to be considered in assigning them to training programs involving high technical skills. Vocational program planning calls for a careful analysis of current market conditions to determine what jobs are actually available to inmates upon release. This analysis includes investigations of union and governmental job restrictions because of certain criminal histories.

Shop and maintenance areas should be supplemented with adjacent classrooms and special training facilities for instruction on new techniques and procedures.

The regulation and inspection of tools are critical functions in a prison. Since all tools must be accounted for each day, they should be stored on shadow boards which automatically indicate when any tool is out of place.

Work Release or Study Release

These programs are usually administered through correctional units detached from the basic prison. These units house those inmates who have qualified for a program of partial release into the community in order to work

Fig. 17 Educational component providing range of spaces in five sizes to offer choice of space appropriate to particular staff-inmate or inmate activity. Folding partition offers opportunity for larger group presentations or dialogues. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

Fig. 18 Teaching components include a multiuse instructional support unit, a mobile audio-visual unit, and a modular carrel unit for individual study. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

or study. This program is often administered as a prerelease phase where inmates generally are transferred to the unit a short time before their release. Work-release inmates must not be mixed with regular prison inmates, since they are often coerced by insiders to bring in contraband from the outside.

Since the occupants of the work-release units are free to work in the community, no physical constraints are necessary in their housing facility. The structure becomes comparable to a college dormitory, and often a private residence is acquired for this purpose, as long as it conforms to normal occupancy, health, and fire standards.

Consideration should be given to locations close to public transportation and within communities where the neighborhood atmosphere permits racially integrated housing. Space needs to be provided for offices, recreation, dayrooms, kitchen, dining room, laundry, and storage, in addition to sleeping areas.

INMATE SERVICES

Library

Library services function as the information and library materials center supporting the total institutional program. The library will provide a significant type of recreation for certain inmates, especially those not interested in or not able to participate in sports. The heaviest use comes during the evening hours, therefore, the library should be located so that adjoining areas with limited operating hours may be closed off without impairing access to the library. The library is best located far from such noisy areas as music rooms or workshops, but easily accessible to housing and close to the educational unit.

The quantity of reading matter in a very small facility, such as a small county jail or prison camp, would be a small reference collection supplemented by a program of book interchange from a general library. Larger facilities need libraries with no fewer than 6,000 volumes, or at least 10 books per inmate. Institutions with high populations of long-term prisoners should provide a minimum of 15

Fig. 19 Library component utilizing individualized reading-study area located remote from distraction of entry circulation-active usage area near entry for ease of access. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

JAILS AND PRISONS

to 20 volumes per inmate. The institution library ought to have access to a general library with a collection of at least 100,000 volumes for reference or interlibrary loan service. Seating space should be allotted for not less than 5 percent of the institution's population, with an allowance of 30 to 35 sq ft per reader for bookshelves, tables, chairs, and circulation. (See Fig. 19.)

Supporting facilities can include a librarian's office and workroom, a magazine storage room, and a listening room with record player. Provisions should be made for transporting books to the segregated maximum-security and infirmary areas to serve inmates who cannot travel to the library. In warmer climates an outdoor area is highly desirable to serve as a reading garden.

Commissary

This is where inmates purchase personal items, such as cigarettes, combs, candy, juice, and as many minor items as the administration wants to stock. A commissary operation may be centralized, so that inmates come in shifts to make their purchases, or it may be the traveling type, with a cart moving to and from the housing units. As a variation of the centralized commissary operation, inmates fill out request slips in their housing area, the slips are then taken to the central commissary where orders are placed in containers and marked for the ordering inmates. The containers are then distributed to them in the housing units.

A central commissary needs sufficient space and display counters for inmates to see the items available, so that they can order without delay. If ice cream or cold drinks are sold, refrigerated storage units must be provided. Ample space must be allotted for storage of stock and for the commissary officer's book-keeping operation. (See Fig. 20.)

Fig. 20 A commissary component with adjacent storage room for stock, corridor located for easy access. (Guidelines for the Planning and Design of Regional and Community Correctional Centers for Adults, University of Illinois.)

Barber

Barber facilities may be located centrally or in individual housing units. If they are decentralized, the chair(s) should be movable for storage while not in use. Generally inmates shave themselves, and barber services only apply to haircuts.

RECEPTION AND DISCHARGE

The reception and discharge unit is the point of institutional entry or departure for all prisoners. The entry process can be important in determining the inmate's later attitudes and behavior since it is his initial institutional impression. The reception process involves booking, examination, clothing issue, classification interview, fingerprinting, photographing, and assignment to a housing section. Sufficient holding areas must be provided where incoming inmates can congregate until the staff is prepared to administer the reception procedure. The holding areas require benches for sitting and toilet facilities in each area. Showers and drying areas should be provided at the reception area, and an examination room and doctor's office ought to be included for medical examinations. Prisoners beginning the process should not have access to those who have completed the process and are awaiting assignment to a housing unit. Most institutions assign new inmates to a special reception housing unit where they undergo orientation, classification, diagnosis, and withdrawal from drugs, as required. Due to the high percentage of drug addicts received by detention facilities, a major segment of newly received prisoners will undergo withdrawal, which is no longer a problem if methadone is administered. The withdrawal period takes from 3 to 5 days, and medical observation must be maintained during this time. (See Fig. 21.)

MEDICAL SERVICES

The correctional institution has an explicit responsibility to protect and maintain the health of inmates and to prevent the spread of disease among the prisoner population. Preventive medical services in a prison begin with the physical examination of each newly received inmate, encompassing any laboratory or x-ray evaluations that may be necessary. Those inmates who are found to be ill upon admission should be placed in the infirmary for treatment. The initial examination demands the identification of chronic illness in new inmates, such as a cardiac condition, tuberculosis, or diabetes, as well as drug addiction.

The centralized medical facilities of a prison consist of an inpatient and outpatient department. The outpatient function consists of the regular daily procedure under which inmates who are ill or require medical attention can report to the physician for examination and treatment. In small facilities the physician may tour the institution personally, but this is not as desirable as having the inmates go to a central facility for sick call. At least 10 percent of an institution's inmate population may be expected to report to sick call daily. An ample waiting area that includes toilet facilities is thus required for inmates waiting for medical attention. Consultation and treatment rooms should be located in close proximity to the clinical laboratory, x-ray, and pharmacy areas.

Inpatient facilities ought to have a full range of accommodations for inmates requiring formal medical attention. Sufficient beds need

to be supplied to accommodate 3 to 5 percent of the total population that will be housed in single rooms and wards. Areas need to be allotted for the isolation of patients with contagious disease, and special facilities for psychiatric patients who require special security and safety devices to prevent self-injury. The range of treatment facilities will vary, depending on general medical facilities available in neighboring communities. Normally, major surgery is performed at a nearby general hospital, although larger institutions may offer partial or full operating suites for emergency use. Basic treatment areas include general examination and treatment, hydrotherapy, physiotherapy, and eye, ear, nose, and throat services. These areas should be closely related to each other and under the direct supervision of the office of the medical director. Support facilities for these treatment areas comprise an x-ray suite, an EKG-BMR room, a clinical laboratory, and a pharmacy. The pharmacy must allow for a secure storage for drugs.

In addition to general medical treatment, a program of dental care requires a dental suite consisting of one or more treatment rooms and a laboratory. The dental suite should be adjacent to the medical waiting room. The dentist will function more efficiently if he has at least two chairs, thus permitting a trained inmate helper to prepare the next patient for treatment.

Fig. 21 A diagram showing inmate flow through the reception component of a detention facility.

FOOD SERVICE

One of the most important and difficult operations in any correctional facility is the preparation and serving of three meals a day to the inmate population and to the staff. Most of the kitchen work will be done by inmates with varying levels of experience or interest, under the direction of a steward and a limited staff. Food service can be improved by providing vocational culinary training as part of the correctional program.

With few exceptions, the food preparation is accomplished in a central kitchen facility having major areas for receiving, storage and preparation of food, cooking, dishwashing, and garbage disposal. The amount of space required for storage of foodstuff depends upon the frequency and characteristics of the food-purchasing and delivery program in the institution.

The point of entry for receiving food items requiring a substantial amount of storage should be supervised by a storekeeper who checks incoming deliveries against orders and designates storage areas in the institutional warehouse. The steward replenishes his daily stock from the warehouse or, in smaller installations with more frequent deliveries, food items are stored near the kitchen for continuous use.

The steward supervises the main kitchen, and his office should be strategically located to promote this control, with maximum glazed vision lights. Facilities for the inmate kitchen detail generally include a lounge, classroom (for special culinary instruction), and toilet. Generally, these inmates will put on their kitchen clothing in their housing unit, but some institutions provide clothing in the kitchen itself which necessitates inclusion of a locker room.

There are several basic methods of inmate feeding, each method having its advantages and disadvantages. An appropriate choice of methods depends upon consideration of the correctional goals of the facility, types of inmates served, available custodial manpower, and relationship to the overall program. The basic feeding patterns are

Central dining room(s) adjacent to kitchen
Local dining rooms in housing units
Feeding in inmates' cells
A combination of the above

Central Dining

Central dining adjacent to the kitchen facilitates delivery of prepared food and return of soiled dishes to the dishwashing area, generally located in the kitchen. Dining may take place in a single room or be sectioned off to reduce an excessively large group of inmates congregating in a single space. The process is usually carried out in shifts or on a continuous basis where inmates leave after they have finished with their meals and other inmates take their seats. Careful planning allows a sufficient area for inmates on line waiting to be seated so that they will not interfere with inmates already eating. The institutional sound system should be extended into the dining area to enable broadcasting of announcements and music programs.

Localized Dining

Localized dining in housing units eliminates the problem of large numbers of inmates congregating together and is more ideally suited to the type of facility that promotes a correc-

tional program based on a group interaction. The local dining room can be used for other program purposes between meals. The distribution of food from the kitchen is achieved by heated food carts, which function as serving steamtables in the dining area. It is generally preferable to return dirty dishes to a central dishwashing facility in the kitchen, since cleaning in accordance with health code requirements necessitates special equipment too difficult and expensive to supply in dispersed locations.

Cell Dining

Cell dining is the least desirable method and should be restricted only to that small minority of inmates who pose disciplinary problems. Even for this group, cell feeding should be avoided by providing a special high-security housing unit with its own dining room. Thus cell feeding will be restricted to the most uncontrollable inmates who generally are a very small percentage of the total population.

Staff Dining

Staff dining is generally treated as a separate function from inmate dining, except in small correctional units that promote a close rapport between staff and inmates. The staff dining hall often is divided into areas for custodial staff and areas for superior officers. These dining facilities should be near a main traffic artery, so that in case of an emergency there can be quick access to the main control points of the institution.

RECREATION

Recreation has been recognized as an integral part of a good correctional treatment program. It alleviates the dull monotony of prison life, acts as a safety valve for the release of pent-up energies that otherwise might lead to disturbances, and can be directed toward helping inmates confront some of their personal problems. A well-rounded recreation program should embrace active, competitive sports and strenuous activities for all inmates who are physically fit and interested. For those inmates who cannot take part in active sports, corrective physical fitness programs and other forms of recreation ought to be made available.

Indoor facilities naturally are essential for a full year-round recreation program. It is expedient to plan the gymnasium area for multiple program uses, so that movies and other auditorium functions can take place there. Without question, the most popular sport among inmates is basketball, particularly when the majority of inmates come from urban centers. The main floor of the gymnasium needs to be available for basketball, volleyball, and other floor games, so a separate area should be allotted for boxing, wrestling, and weightlifting, another popular prison activity. Spectator seating ought to be portable to increase the maximum activities space when seating is not required, yet easily brought in for movies or shows. Lockers and showers need to be supplied for inmates and visiting teams.

To meet requirements for basketball and volleyball activities, a gymnasium floor has to be at least 60 ft wide and 100 ft long, with a clear height of 20 ft. For competitive play, a gymnasium floor length of 100 ft is desirable. In addition to a main basketball court, allowances ought to be made for side practice courts

to accommodate a maximum number of users at a time. Floor inserts will enable the quick installation of a volleyball net as an alternate activity.

Besides the indoor facilities, outdoor recreation space is necessary for a complete recreational program. On urban sites where outdoor space is not available, it is wise to use roof surfaces to their maximum. These areas generally require fencing enclosures at the sides and top. Where the site is not restrictive, yard and field areas should be provided to supplement the indoor programs. It is expedient to locate outdoor recreation fields adjacent to the gymnasium if possible, to permit common use of lockers and controlled distribution of athletic equipment. The athletic field needs to be adequate for football, baseball, soccer, softball, basketball, and handball, with smaller activity areas for shuffleboard, horseshoes, and bocci ball supplementing it.

VISITING

There are two basic types of visiting done in a correctional facility, visits with family and visits with attorneys and caseworkers.

Visits with family are encouraged to sustain family ties until the inmate's release. Each institution establishes controls for the frequency and length of visits, depending primarily upon the staff available for supervision. Different types of institutions and different kinds of prisoners impose varying custodial restraints, requiring diverse visiting accommodations. Some prisoners and visitors require separation by physical barrier to maintain safe custody and prevent passage of contraband. Others can meet without incident in an informal furnished living room where they may embrace and sit alongside one another under observant supervision.

Closed Visiting

Closed or secure visiting room consists of a booth with a complete physical barrier separating the inmate and visitor. A large expanse of tempered or laminated glass permits visual contact while aural contact can be effected by telephone or microphone-speaker arrangement.

Open Visiting

Open visiting allows contact and normal conversation between inmates and visitors. Since constraints are more relaxed, it is desirable to provide an outdoor area adjacent to the visiting room for use in warm weather. Visitors should leave packages and handbags outside of the visiting room, however, and for this purpose an alcove containing small lockers is attached to the visitors' waiting room. In some instances, prisoners change clothing for visiting and are thoroughly searched before and after an open visit, a security measure intended to guard against the introduction of contraband.

Conjugal Visiting

Conjugal visiting deserves serious consideration for any sentence institution that hopes to encourage normal sexual adjustment among inmates. While the problems associated with conjugal visiting are numerous and its practice under present prison regulations might not completely fill the sexual needs of an inmate, conjugal visiting does allow a man to retain his masculine self-esteem and reduce the

JAILS AND PRISONS

need to establish it through homosexual conquests. These facilities should be totally removed from the prisoner population and offer complete privacy to the couples, with quarters that do not reflect the institutional character of the prison.

Attorney and Caseworker Visiting

Attorney and caseworker visitation ought to occur in a central location close to the institution's main entrance to avoid excessive outside traffic into the heart of the prison. The privacy and confidentiality of visits between a prisoner and his attorney must be completely respected, and visiting rooms should be fully enclosed with liberal glassed-in areas for visual observation by custodial officers.

RELIGION

The actual services that take place in a chapel are only a small part of a complete religious program, which includes religious education, counseling, and contact with inmates' families and visitors. The institutional clergymen require individual offices, preferably near the chapel, to carry out their administrative responsibilities. In many institutions, the chapel is used for other nonreligious functions and may act as an auditorium or gymnasium. Within a limited physical plant, this may be an efficient multiuse of a space, but it is obvious that if conditions permit, it is far more desirable to designate a chapel area exclusively for religious activities. Separate chapels for each faith group are preferable, but an interfaith chapel can be equipped with a revolving altar to serve the three major faiths.

SECURITY CONTROL

Security control in a correctional institution is effected by every component of the institution, including layout and design of building elements, details of operation and construction, and the skilled and intelligent supervision of prisoners by a competent staff.

Central Control

Central control is monitored by a control room that functions as the nerve center of the institution. This area is constantly in complete operation, acting as the custodial center for key control, communications, alarm, and traffic control.

The control room operates a series of electrically interlocked doors to fully supervise entrance and exit from the custody zone of the

institution. Ideally, the control room should have visual access along the major traffic corridors. If a system of closed-circuit television is used to view key points in the institution, the monitor screens also must be located in the central control room. All institutional keys should be stored in the key cabinet of the control room and furnished to officers at the beginning of their tour of duty and returned upon tour completion. The communications network of the institution, including security telephones, public address systems, and paging systems, ought to be controlled from this area, as well as all alarm systems, including general emergency alarms, and indicators for opening key doors or operating elevators. It is wise to locate a system of traffic control in or adjacent to the central control room to indicate at any given time the housing location of each inmate.

Firearms

Firearms should be stored in a secure depository at the main entrance of the institution. Many official visitors to a detention or sentence institution will be in possession of firearms, but these must never be permitted inside the custody portion of the facility.

Vehicular Access

Vehicular access to an institution with a perimeter security enclosure should be through an entrance vestibule with doors and gates at each end, both of which ought never to be unlocked at the same time. Frequently, large vehicle gates are motor-operated, controlled from a nearby tower or other control point.

Locks and Locking Devices

Locks and locking devices in correctional institutions ought to be fabricated and installed by manufacturers who specialize in these devices and have a proven record of satisfactory installation. Prison locks should be of the dead-bolt type, requiring the officer to turn the key in the lock for positive proof of security. Locking devices for rows of cells are generally controlled from cabinets at the front corridor of a cellblock. Basic sliding cell door locking devices fall into four categories.

Manual Gang Locking All doors can be deadlocked or unlocked as a group by moving levers in a control cabinet. Individual doors are locked or unlocked by a key at the door. Doors are moved manually by the inmates.

Electromechanical Selective All doors are locked or unlocked and operated individually or in groups from switches in a control cabinet.

Any door can be manually unlocked or locked by a key at the door without interfering with the electrical operation.

Manual Keyless Selective All doors are locked or unlocked and operated individually or in groups by moving levers in a control cabinet.

Keyless Electric Selective All doors are locked or unlocked and operated individually or in groups from switches in a control cabinet. There are means of unlocking and locking doors individually or in groups in the event of an electrical power failure.

SUMMARY

In the past, when an architect was assigned to a correctional project, he was relegated to the status of technician or draftsman by the corrections agency or local sheriff. He was handed an outline of basic area requirements and given instructions about their predetermined functional relationships. He rarely interviewed correctional staff representing the various program disciplines and did not explore extensively any alternative solutions to program requirements.

The result? In 1970 a survey of the nation's 4,037 jails found that 86 percent had no facilities for recreation or even exercise, 89 percent lacked educational facilities, 49 percent lacked medical facilities, 26 percent were without visiting facilities and 1.4 percent even lacked toilets.

Attempts have been made to liberalize and develop programs hampered by archaic physical plants, where environment is measured not by its effect on men, but by the strength of steel. There the difference between maximum- and medium-security construction is defined by the time it takes to cut through a steel bar or by the height of a wall.

Change is apparent. Today's architect should question the very need for a correctional institution to begin with. He should challenge the program's constraints, including requirements concerning security, indestructibility, location, and he should analyze the program's capability to ensure that past mistakes are not repeated. The era of the stereotype prison is over. Each community must plan and design in accordance with its own needs. New facilities need to be drawn into populated areas where professional staff, services, educational institutions, and human contact can integrate the offender into community life. The new corrections theory is not based on brick, mortar, and steel, but rather on the interaction between skilled professionals and the offenders within a therapeutic setting.

Proper location of the incinerator enhances acceptance by the public and results in economies in waste collection. A well-planned physical layout facilitates efficient and economic incinerator operation. Good design and selection of appropriate building materials promote a pleasing appearance and minimize housekeeping and maintenance.

Site Selection

Public Acceptance Public acceptance is a most important consideration in selecting an incinerator site. A few suggestions for gaining public acceptance follow.

1. Choose a site where construction can conform with existing and planned neighborhood character. In general, industrial and commercial areas are more compatible with incinerators than residential areas. An incinerator plant is usually classed as heavy industry, and the evaluation of its location should reflect this. Too frequently the vacant land surrounding an incinerator is later developed for residential or other restricted use, which creates conflict. To avoid potential conflict, the undeveloped, surrounding land should be zoned for industrial use.

2. Avoid choosing a site that may conflict with other public buildings. The noise, lights, and 24-hr work day of normal incinerator operation preclude locating it near a hospital, and heavy truck traffic makes incinerator location near schools undesirable.

Centralized public works operations are desirable. Often an incinerator plant can be advantageously located near a sewage treatment plant so that technical services may be shared. There may be economies in locating the incinerator near a garage where vehicle repair facilities and personnel can be shared.

3. Where conflict with neighborhood character is unavoidable, the screening effects of a wall or planting can reduce adverse effects and gain public acceptance. Good architectural design is itself a major asset in overcoming potential neighborhood objection.

4. Institute an effective public relations program. Before full site and design decisions are made, proposals and plans should be presented through the press and for discussion at public meetings. This would serve to demonstrate management response to community desires and a capability for operating an acceptable facility. Presentation of alternatives along with rationale for incineration may be supported by graphic examples and site visits to successfully operating facilities.

Site Suitability Factors important to design, but generally not of concern to the public, are foundation conditions, topography, availability of utilities, building restrictions, drainage, and meteorologic conditions.

Soil and rock formations determine the type of foundation required to support the heavy, concentrated load of an incinerator structure.

Failure to accurately determine foundation conditions and design to them can result in expensive modifications during construction and, in certain cases, abandonment of the site with its partially completed structure. Groundwater conditions also affect design and cost.

Topography and meteorological conditions must be considered in the location and the design of the incinerator. A flat site is apt to require a ramp for access to the tipping floor, whereas a hillside site can provide access at various ground levels. Topography can also ease or hinder the dispersion of gases and particulates by the local atmosphere. This aspect of plant location is complex and requires the assistance of a meteorologist or air pollution control specialist, who can determine the best stack height for the dispersion of gases. Stack height determination requires consideration of topography and legal restrictions, such as those from Federal Aeronautics Agency regulations, local building regulations, and zoning.

Availability of public utilities may be a governing factor in site selection, since electricity, gas, water supply, sewage disposal, and process water disposal are essential to the incinerator process. Fuel such as gas or oil may be required at some installations as an auxiliary heat source for the furnaces or as building heat. Communication facilities must be available for fire and safety control and for coordinating operations.

As in the development of any industrial site, effective drainage of surface waters must be an integral part of design. The site should not be selected in an area subject to flooding unless the facility can be protected and access remains available during high water.

Traffic Consideration The ideal location for an incinerator is at the center of the traffic pattern produced by the contributing collection vehicles. A major argument already made for incineration in comparison with land disposal was that incineration can reduce the time and cost of collection haul. This requires that the incinerator be centrally located. This is not always feasible for a variety of reasons. For example, future growth and its effects on the collection source must be considered.

A large plant may have literally hundreds of vehicles delivering solid waste in relatively short time intervals. Because of heavy traffic, the plant must have adequate access to preclude safety hazards in the streets of the area. Special access roads may have to be provided so that the trucks avoid heavily traveled highways. Special consideration also must be given to traffic impediments such as bridges with low weight limits, restrictive heights of overpasses, narrow pavements, and railroad grade crossings with high-volume traffic. A location that avoids commuter traffic is also preferred. Thus, a plant located near the edge of the participating community but readily accessible by freeways or beltways may be better than one centrally located. The same traffic considerations apply to residue disposal. On-site disposal is often not possible; therefore, incinerator residue and nonburnables must be trucked to a landfill.

Plant Layout

An incinerator plant layout should promote ease, simplicity, and economy of operation and maintenance. There should be adequate room for all parts of the operation. The structure should harmonize with the surrounding neighborhood and should be so oriented that unsightly parts of the building and operation (such as receiving and storage) are not visible to the public. In certain climates, it is advantageous to orient the receiving area on the leeward side of the prevailing wind. The on-site road pattern should allow ready access to scales and receiving area and an easy exit; one-way traffic is most desirable; sharp turns and blind spots should be avoided; and a large parking apron should be provided outside the receiving area to avoid congestion during peak receiving hours.

Adequate drainage is necessary for surface waters. Incinerator operation requires periodic hosing of tipping floor, vehicle wash areas, parking aprons, and ramps. The paving should be sloped and contain adequately sized and strategically placed drains. This is particularly critical in cold climates where ice formation could interfere with operations.

Maintenance and storage of trucks may be inside the incinerator building or on the grounds, but these areas must be located where they will not hamper the operation of the incinerator.

Building Design

The incinerator should be aesthetically pleasing and should be constructed of durable, high-quality materials and fixtures to reduce maintenance. Materials requiring a minimum of painting or resurfacing, such as concrete, tile, and noncorrosive metals, should be used. Surfaces that require painting should have a dense, durable finish. Corners and bases can be coved to reduce accumulation of debris and allow easier cleaning. Where possible, piping and duct work should be enclosed.

Personnel Facilities Adequate facilities for incinerator personnel are more a matter of convenience and may well represent the difference between a working situation that is conducive to efficiency and cleanliness as opposed to one that may create an indifferent and inefficient work crew. A clean locker room is needed, with adequate toilet, lavatory, and shower facilities. Lockers should have space for storing hard hats, rain and winter gear, and a full change of clothing. Sanitary facilities should be provided for women who may visit or be employed at the plant.

Lunchroom facilities should also be provided, along with a sink and suitable outlets for coffee percolators. Drinking water should be available on every floor and within 200 ft of employee stations. The lunchroom, locker room, shower, and toilet areas should be well lighted and kept clean at all times to encourage habits of cleanliness by the workmen. It is often desirable to provide washroom facilities convenient to collection personnel, weighmasters, and others.

Governmental and Public INCINERATOR PLANTS

Control Room Many large incinerators are now being built with glassed-in control rooms so located that the incinerator superintendent or shift foreman can readily observe various operations. Because all areas of the plant or operating conditions within furnaces cannot be observed from one location, closed-circuit television is used in some instances. The importance of the glassed-in area (ventilated and air conditioned) is not merely to provide comfort to the superintendent and foreman but to protect delicate recording instruments from dust and to minimize the noise level in an area where telephones are used. Written records are also better maintained in an isolated control room area. The control room should be suitably equipped with remote reading and recording instruments that provide supervising personnel with the information necessary to adjust the incinerator operation if it is not performing suitably.

Administrative Offices and Conference Room In the larger incinerator plants, sometimes the superintendent, foremen, and clerical workers need an office to conduct necessary administrative activities. Attractive decor and air conditioning will improve morale and efficiency. Smaller incinerators may effectively combine the operating control room with space for administrative activities.

At larger plants, a conference room for staff briefings, safety discussions, and training purposes is a worthwhile investment.

Weighmaster's Office The weighing activities may be conducted alongside the access road outside the incinerator plant or at the entrance to the turning and tipping area within the plant proper. In either instance, the weighmaster should have a facility with ample glassed area to observe the movement of weigh scale traffic. He should have ready means of communicating with the driver, handling credit cards, or making cash transactions.

Maintenance and Repair Facilities Regardless of the size of the incinerator, storage space for electrical, mechanical, and refractory parts and an enclosed area where repair and subassembly may be performed must be provided. For very large plants, separately maintained storerooms for parts, electric shops, mechanical shops, and enclosed refractory storage facilities should be included. Where a large municipality has a number of incinerators, central maintenance and repair facilities for major activities may prove economical. There should be storage facilities for such items as lawn mowers, skip loaders, mechanical sweepers, refractories, pipes, insulation material, and the various chemicals required for insect and other pest control.

Laboratory The incinerator must be so operated that the environment is not polluted. Federal, state, and local regulations are becoming more restrictive. Surveillance of the water quality of incinerator effluent is needed to ensure pollution control, and a small laboratory and testing equipment should be provided for this purpose. Municipalities with several incinerators should consider a centralized laboratory facility.

Plant Exterior

Roadways, Sidewalks, and Parking Areas In designing the roads providing ingress to an incinerator site, consideration must be given to peak

loading periods and types of vehicles that may utilize the incinerator. Where possible, the roadway system should be built so that the traffic flows only in one direction, thus providing only one entrance and one exit. Arrangements must be made for obtaining truck tare weights without interfering with one-way traffic flow. This is possible even where scales are used, provided the trucks being serviced all have established tare weights. When transient traffic is being weighed, so that a "weighout" is necessary, a roadway may be provided within the site that will allow the trucks to return across the scale for the second weighing in the same direction as the normal flow of traffic. All roadways should be sufficiently wide to permit the passage of one vehicle past another in the event that a truck is stalled. Road grades should be suited to the traffic operating on the grades. In general, the grades for short-distance truck travel should not exceed 7 percent uphill and 10 percent downhill. Pavements should be hard surfaced, all weather, and designed for heavy loads. Curbing, posts or guardrails should be used to confine traffic to roadways.

Incinerator plants should be provided with sufficient sidewalks to ensure that visitors and plant personnel will be able to walk safely about the premises without being endangered by vehicular traffic.

Parking areas are generally divided into two categories: (1) parking for administrative and operating personnel, visitors, and temporary parking for collection vehicles, (2) parking for overnight storage of collection vehicles and for equipment used at the incinerator site, such as mobile sweepers. In areas with severe winters, parking facilities inside heated garage areas are desirable to permit proper maintenance, cleaning, and protection of the collection vehicles.

Landscaping Perimeter planting around an incinerator site presents a pleasing appearance and reduces the noise of the truck traffic from within the property. For maximum benefit and to further enhance the appearance, trees and shrubbery can be placed outside the fencing. Provisions must be made in advance for adequate watering and for access so that periodic trimmings may be performed without unreasonable expense. Built-in sprinkling systems should be considered for lawn and shrub areas.

Fencing Where the incinerator plant is located in an area subject to vandalism, peripheral fencing with a minimum height of 6 ft is desirable.

UTILITIES

For efficient operation, a municipal incinerator requires certain utility services, which include: (1) electricity for power and lighting; (2) potable water for plant personnel and suitable process water for spraying, heating, quenching, cooling, and fire fighting; (3) telephone service; (4) sewerage systems for handling process waste and sewage, and storm sewers for drainage; (5) fuel for heating, hot water, auxiliary heat for incineration, and possible laboratory use. Each of these utilities supplied to the incinerator site must be metered and distributed safely and efficiently to all points of usage at the site.

With increasing incinerator capacities and with increasing use of sophisticated equipment and devices, more utility services will be

required. The cost of providing these utilities depends on the plant design and mode of operation.

Electric Power

With few exceptions, utilization of incinerator waste heat to generate electric power is not practiced in the United States. The incinerator's electric power is obtained from other sources.

Electric power requirements vary with the degree of mechanization and the use of equipment. Common examples of equipment requiring electricity are induced draft fans, forced-air fans, pumps, cranes, hoists, air pollution control devices, and grate-driving mechanisms. Allowance for future electrical needs should be included in planning and sizing the electrical distribution systems.

Water Requirements

The quality of the water required for incinerator operation will depend on its use. Sources may include: city water, on- or off-site wells, rivers, lakes, and waste-water treatment plant effluents. The total amount of water required may vary from 350 to 2,000 gal per ton of waste incinerated, depending on design and operation. Incinerator operation requires a dependable water supply. An elevated water supply serves this purpose and can be used for fire fighting. When waste heat is used to produce steam or hot water, the boiler feedwater and makeup water will require extensive pretreatment. Water for air pollution control equipment, for gas cooling, and for dust control sprays need not be potable but should be free from suspended materials. Water used in the incineration processes will increase in temperature, change in chemical characteristics, and will acquire solids. Treatment may be required before these waters are discharged.

The costs of water recycling and reuse should be investigated. In reuse and recycling, treatment should be effective in preventing clogging, erosion, and corrosion of equipment.

Sewers

Preferably, the incinerator should be located in an area served by sanitary sewers. Untreated waste process water should be disposed of through the sanitary sewer if the system is capable of handling it. Storm sewers should be used only for discharge of surface waters.

WEIGHING

An incinerator scale weighs incoming solid waste and outgoing residue, including fly ash and siftings. It may also be used to weigh salvaged materials. Accurate and meaningful weight records can be used to improve operation, to assist management control, to facilitate planning, and to provide an equitable means for assessing fees. Weights are needed for cost accounting, rating the effective capacity of the incinerator, testing air pollution control devices, and making a materials balance for the facility.

A management system making use of weights can serve to regulate and control solid waste collection and disposal. Good collection scheduling and routing may depend on such a system. Distribution of waste deliveries among available plants requires prompt access to weights of incoming material. Cost control

to increase efficiency and eliminate excessive expenditures of time and effort is dependent on weight units.

Observation of the trends in quantity, sources, and types of solid waste collected will assist in planning for future disposal needs. Weight records of residue assist in determining the remaining life of residue disposal sites and thus assist effective planning as well as provide a means of calculating combustion efficiency. If a community wishes to charge other communities, private haulers, or commercial haulers for using the incinerator, the weight measurements will provide a practical, equitable means for assessing fees.

Scale Description

Scale Types A small incinerator (50 to 100 tons per day) may satisfactorily use a wood platform, manually operated, mechanical scale and keep handwritten records. At the other extreme, large incinerators frequently use automatic systems employing load cells, electronic relay, and printed output. The electronic relay scales allow for greater flexibility in locating the scale platform in relation to the scale house. Highly automated electronic scales and recorders are more costly than simple beam scales; however, they are justified in many cases because they are faster and more accurate.

Size and Capacity The scale should have sufficient capacity to weigh the largest vehicle anticipated to use the incinerator on a routine basis. The platform should be long enough to accommodate simultaneous weighing of all axles. Separate axle loading scales, although less expensive, are inherently inaccurate and slow in operation. For simultaneous weighing of all axles, the majority of collection trucks could be accommodated with a 10- by 34-ft platform. A 50-ft platform will accommodate most trailers and semitrailers. Scales should be capable of weighing loaded vehicles of up to 30 tons.

Accuracy The accuracy and internal mechanism of the scale and recording mechanism should meet the commercial requirements for the state or other jurisdictions involved. This is particularly necessary if user fees are based on weight. Recommended scale requirements have been outlined by the National Bureau of Standards.

Platform The platform or deck of a scale may be constructed of wood, steel, or concrete. Wood decks are least expensive but least durable. Many large truck scales have a platform constructed of reinforced concrete.

Scale Pit Scale-pit walls are usually concrete and should be set in a suitable foundation to control settlement. A paved scale-pit floor facilitates cleaning and maintenance. In all cases, scale-pit drainage is essential. Scale-pit depth should be sufficient to allow periodic inspection and maintenance of the scales. Access to the pit should be through the wall or through a hatch on the platform. Gutters around the edge of the scale pit to intercept runoff from the deck have been used effectively to ensure a dry, clean scale pit. Lighting should be provided to aid in inspecting and maintaining the scale mechanism and in cleaning the scale pit.

RECEIVING AND HANDLING SOLID WASTE

Solid waste is delivered, usually during the day shifts, in several types and sizes of trucks and vehicles. The vehicles are first weighed and then proceed to the tipping area. At large installations, the trucks unload into a storage pit, whereas at small incinerators, the practice has been to dump the waste directly into the furnace charging hopper or onto the tipping floor.

After the waste has been unloaded into the storage pit, the material must be transferred to the charging hopper. For incinerators with charging hoppers located above the storage

pit, the transfer is usually performed by overhead cranes. Some incinerators have the charging floor on the same level as the storage area, and transferring is usually done with a front-end loader or special equipment.

The solid waste is charged into the furnace by dropping it directly through a gravity chute or pushing it into the furnace with a ram. After deposition, the waste is mechanically moved through the furnace.

Tipping Area

The tipping area is the flat area adjacent to the storage pit or charging hoppers where trucks maneuver into position for dumping (Fig. 1). The area should be large enough to allow for safe and easy maneuvering and dumping.

Dimensions Collection trucks tend to arrive at the incinerator in large numbers during a short time interval. To avoid a backup of trucks, the length of the tipping area and storage pit should receive careful design consideration. The total length of the tipping area should extend the length of the storage pit and, if possible, beyond the pit. Width of individual dumping spaces along the pit should be about 10 to 12 ft. These spaces should be clearly marked. Support columns should be placed to avoid interfering with dumping spaces.

The tipping area width should be greater than the turning radii of trucks using the tipping area. For single-chassis compactor trucks, the radius is between 25 and 35 ft; for tractor trailers, the radius is between 35 and 50 ft. The minimum recommended width of the tipping area is 50 to 70 ft; if the space is available, the width should be larger.

The entrance, exit, and ceiling of an enclosed tipping area must be high enough to provide the necessary clearance for dump trucks. Ceiling height is critical at the edge of the tipping area when the packer and dump bodies are raised in the unloading position. A minimum of 25 ft is recommended, but greater vertical clearance may be necessary for some trucks.

Vehicle entrances and exits should provide a minimum of 18 ft of vertical clearance. Exits should be provided with warning devices, such as hanging chains, to prevent careless drivers from attempting to exit with raised dump bodies. The entrance and exits should be equipped with wheel guards to protect the door jams.

Tipping Floor Enclosure Enclosing the tipping area should be considered. Climatic conditions may make it desirable. In addition, an enclosed tipping area is definitely recommended for good public relations. Dust control, odor confinement, and noise reduction effected by enclosure will help make the incinerator more acceptable to the community.

Other Aspects of Tipping Area Design The floor of the tipping area should be constructed to withstand the heavy loads placed on it; it should slope away from the storage pit toward a drain so that the area can be regularly cleaned and flushed. The floors are usually rough surfaced for traction.

Because of the debris that accumulates in the tipping area, the drainage system is required to accommodate large quantities of wash water. The size of the receiving sewer is critical if the discharge is to such a system. Bar grates or other suitable devices can be used to prevent large objects from being discharged to the sewer and possibly obstructing flow.

Fig. 1 Plan of tipping area and storage pits with crane.

Governmental and Public INCINERATOR PLANTS

Scattered dust and litter from the dumping, recasting, and charging operations are problems common to solid waste handling. Provisions for cleaning the tipping area should be considered during the design phase. Vacuum cleaning facilities, a compressed air system for cleaning electrical contacts, powered mobile sweepers, and flushers have been successful in controlling the spread of dust and litter.

Because of dangers involved in the handling and dumping of large trucks in close quarters, safety in the tipping area should be stressed by the incinerator supervisor. Hold-down chains or bumper picks are sometimes employed to prevent trucks from being tipped into the pit; however, use of these safeguards is time consuming, and short ramps sloping away from the storage pit at an angle of 8 to 12° from the horizontal will prevent mishaps efficiently.

Most plants are constructed with a curb or backing bumper along the entire length of the pit to prevent trucks from backing into the pit. This barrier must be high enough to prevent trucks from overriding yet low enough to permit the chassis overhang to clear the curb. A height of about 1 ft is considered adequate. The face of the backing bumper is usually vertical or slightly concave to conform to the shape of the wheel. The barrier must be durable enough to withstand repeated impact and must be securely anchored to prevent movement. It should contain openings so that spilled waste can be shoveled or swept from the tipping floor into the pit.

Other measures to be considered for the safe operation of a tipping area are: (1) designing tipping area, storage pit, and crane to eliminate possibility of crane bucket striking extended dump body; (2) using a traffic director at larger incinerators; (3) permitting the dump bodies of packer trucks to be raised only when the truck is in the unloading space.

Storage Pit

The purpose of the storage pit is to provide a safe and convenient holding place for solid waste before it is charged to the incinerator. In a properly designed storage pit, waste from numerous sources can be mixed to provide a more uniform feed for the furnaces.

Capacity of the Storage Pit When the rate of receipt of solid waste exceeds the burning rate, material must be stored for future processing. The total space for storage depends upon the amount of material remaining after the daily receiving period and the amount that is left unburned from day to day during times of peak waste delivery. The storage pit is usually designed to contain about 1.5 times the 24-hour capacity of the incinerator. If heat recovery is practiced, the pit storage capacity should receive special study to ensure a supply of solid waste adequate to meet the heat demand when waste is not delivered to the incinerator.

To calculate the necessary storage volume, the unit weight of solid waste in the storage pit must be known. The generally accepted average unit weight of waste in a storage pit is about 350 lb per cu yd.

When designing storage pits, future changes in waste density should be considered. As noted, in recent years, solid waste density has been decreasing.

Other Aspects of Storage Pits Storage pits are usually rectangularly shaped because of crane design and ease of construction. A rectangular pit allows the crane supports to be constructed with the use of the existing pit walls and bracing.

Some pits are divided into separate rectangular units with charging hoppers between units. With this design, a fire that may start in a pit can be isolated, and pit cleaning is facilitated because of the ability to alternately empty the pits.

The width of a storage pit usually does not exceed 30 ft. Minimum width is usually 15 to 20 ft or wide enough to allow a monorail crane to operate without being obstructed by the overhang of trucks in the dumping position.

The walls of the pit must withstand the external forces caused by water and soil and the internal pressures of solid waste and water in the pit, a condition that could occur during pit fires. During crane operations, the crane bucket may collide with the wall and crush the concrete. Continuous steel plating or embedded steel T-sections in the concrete can protect areas of the pit subject to repeated impact.

Fires occasionally develop in the pit. They can be caused by sparks carried over by the crane during the charging operation, by live coals in the collected waste, or by spontaneous combustion of stored waste. Smoke and heat can damage the crane, break windows, and ruin equipment. Crane damage can put the entire plant out of operation for weeks or longer. The pit area should be equipped with an adequate number of fire hoses of effective size. The dewatering facilities must be adequate for the expected quantities of water used in fire fighting. Portable pumps help to remove excess amounts of water.

The entire pit should be watertight and sloped to troughs and drains for dewatering. When a pit is constructed below grade, it will usually be necessary to have a sump. Screening devices to prevent material from entering the sump are also recommended.

The sources of water and the resulting quantities vary with the installation. When pits are not watertight, leakage can occur as a result of the positive hydrostatic pressure of groundwater. Waste collected in wet weather may be saturated, and vertical drainage will occur in the pit. Water from dust control sprays also enters the pit.

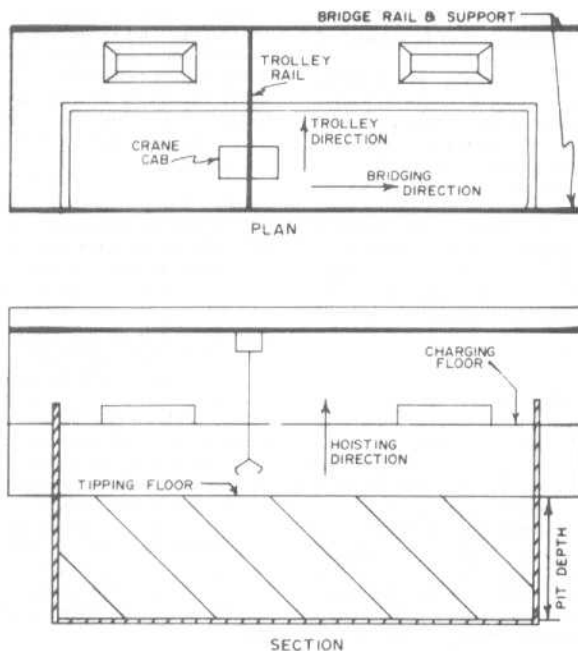

Fig. 2 Plan view and section view of bridge crane.

Cleanout facilities are needed to empty the pit if the furnace equipment breaks down or to remove unwanted items inadvertently unloaded into the pit and remove saturated waste after a fire. A loading shaft from the charging floor to the ground level is useful for unloading the pit and for hoisting heavy equipment and material from ground level to the charging floor (Fig. 1).

Charging Methods

Solid waste is charged into the furnace by several methods. In small installations where the storage area is on the same elevation as the charging hoppers, a front-end loader, vibrating hopper and conveyor, or other mechanical means are used. At larger incinerators, cranes charge the solid waste.

Besides transporting solid waste to the charging hoppers, cranes also mix and distribute the solid waste in the pit. This action results in a more uniform burning material and better utilization of pit capacity.

Crane Types The types most commonly used are the monorail crane and the bridge crane (Fig. 2). The former is a fixed unit suspended from a single rail that crosses the pit in only one horizontal direction. The bridge crane differs from the monorail in that it can maneuver horizontally in two directions rather than one. The capacity of the monorail crane is usually less than that of a bridge crane; the width of the storage pit is restricted to include only that lateral area within reach of the open bucket. Capital cost of a monorail crane is less than that of a bridge crane, and at some incinerators, its performance may be adequate.

Crane Capacity and Bucket Design The size of crane needed to operate an incinerator is a function of incinerator capacity. Each continuous-feed-type furnace requires a given number of bucket loads at regular intervals. The size of the bucket, therefore, is a function of the 24-hr furnace capacity and number of bucket loads per 24 hr. Once the size of bucket has been fixed, the crane capacity can be specified. For

example, a 4.5-ton crane is recommended for use with a 2.5 cu yd bucket.

The number of bucket loads that can be charged during a given period depends upon the number of cycles that the crane can make during the charging operation. A cycle is defined as the time for loading and lifting the bucket, trolleying and bridging to the charging hopper, dumping, and returning for another bucket load. Typical cycles vary from 1½ to 3 min. To determine the cycle time, the hoisting, bridging, and trolleying speeds must be known, as well as the length, width, and depth of storage pit. Typical hoisting and trolley speeds are between 250 and 300 ft per min, whereas bridge travel speeds may be as high as 350 ft per min. In general, design criteria do not require high speeds.

Incinerator cranes usually use the closed-scoop bucket or a grapple. The closed scoop is a clamshell with heavy steel lips usually equipped with short teeth to increase penetrating ability. The grapple type is similar to a clamshell but has much longer teeth, called tines. This type has a considerably larger capacity than an equally rated closed-scoop bucket. The grapple is a poor cleanup tool because of the length and spacing of its tines. For cleaning purposes, the grapple can be equipped with bolted-on pans.

Number of Cranes Crane downtime will stop incinerator operations unless a standby crane is provided. Nearly all installations with a capacity above 400 tons per day (TPD) have a second crane to prevent shutdowns. A second crane is recommended for plants with over a 300-TPD capacity. Because of high costs, most small plants have only one crane. At larger installations, a third crane is often justified, and nearly 50 percent of the plants with over a 850-TPD capacity have three cranes. With a second or third crane, space in addition to the operating space required for the first crane must be provided for the storage of the units when not in service. The point of storage for the nonoperating units must not interfere with the operating unit.

Control and Operation The crane can be operated manually from a cab traveling with the crane or from a remote fixed operating point. Manual operation from a mobile cab has some advantage over a remote fixed operating point. The operator has better visibility, which usually yields better and safer operation. Where the pit is long, the distance judgment error is reduced with mobile cab operation.

When a mobile cab is used, the operator should have a safe, convenient boarding platform. Since the charging operation may be dusty and hot, the crane cab should be air-conditioned.

Charging Hoppers

Charging hoppers are used to maintain a supply of solid waste to the furnace. In batch-fed furnaces, a gate separates the charging hopper from the furnace and supports the solid waste while the furnace is burning the previous charge. Generally one hopper is provided for each furnace cell. In a continuous-feed furnace, the waste-filled hopper and chute assist in maintaining an air seal to the furnace as well as to provide a continuous supply of solid waste.

Most charging hoppers have the shape of an inverted, truncated pyramid. The size of the hopper opening depends somewhat upon the size of the furnace, but it should be large enough to prevent arching of oversized material across the hopper bottom. Common hopper

openings measure from 4 by 4 ft to 4 by 8 ft. The hopper should be deep enough to receive a bucketful of solid waste without spilling over.

The charging hopper is generally steel- and sometimes concrete-lined. Because of abrasion from solid waste, impact from the crane bucket, and heat from the furnace, the hopper must be constructed of rugged material and built to facilitate repair and replacement.

Charging Chutes

The charging chute connects the hopper to the furnace and may be nearly as wide as the furnace, so that the solid waste will pass through the chute without clogging. The discharge of waste into the furnace is usually by gravity, but reciprocating or vibrating feed mechanisms may also be used. Several measures may be taken to prevent solid waste from clogging chutes. These include the use of smooth inside surfaces; corrosion resistant materials; and vertical (or nearly vertical) chutes with increasing cross section.

The charging chute, because of its proximity to the furnace, should be protected against extreme heat. For this reason, chute walls are often water jacketed. A hopper cover or other means of closure should be provided for ending a burning cycle in continuous-feed furnaces.

FURNACES

Incineration is a controlled combustion process for burning solid, liquid, or gaseous combustible waste to gases and to a residue containing little or no combustible material. When solid waste is exposed to a turbulent atmosphere for a critical time period at an elevated temperature, combustion occurs. During com-

bustion, moisture is evaporated, and the combustible portion of the solid waste is vaporized and then oxidized. Concurrent reactions are the oxidation of metals and the oxidation of such elements as sulfur and nitrogen. Carbon dioxide, water vapor, ash, and noncombustibles are the major end products of combustion.

The combustion processes take place in the furnace of the incinerator, which includes the grates and combustion chambers. There are numerous designs or configurations of furnaces to accomplish combustion, and, to date, no one design can be considered the best.

Furnaces

Furnaces commonly used for the incineration of municipal solid waste are the vertical circular furnace, the multicell rectangular furnace, the rectangular furnace, and the rotary kiln furnace. Although these furnaces vary in configuration, total space required for each is based on a heat release rate of about 18,000 Btu per cu ft of furnace volume per hr, although heat release rates varying from 12,500 to 25,000 Btu per cu ft per hr have been used.

The vertical circular furnace is usually refractory lined. Solid waste is charged through a door or lid in the upper part (usually the ceiling) and drops onto a central cone grate and the surrounding circular grate (Fig. 3). Underfire forced air is the primary combustion air and also serves to cool the grates. As the cone and arms rotate slowly, the fuel bed is agitated and the residue works to the sides where it is discharged, manually or mechanically, through a dumping grate on the periphery of the stationary circular grate. Stoking doors are provided for manual agitation and assistance in residue dumping if required. Overfire

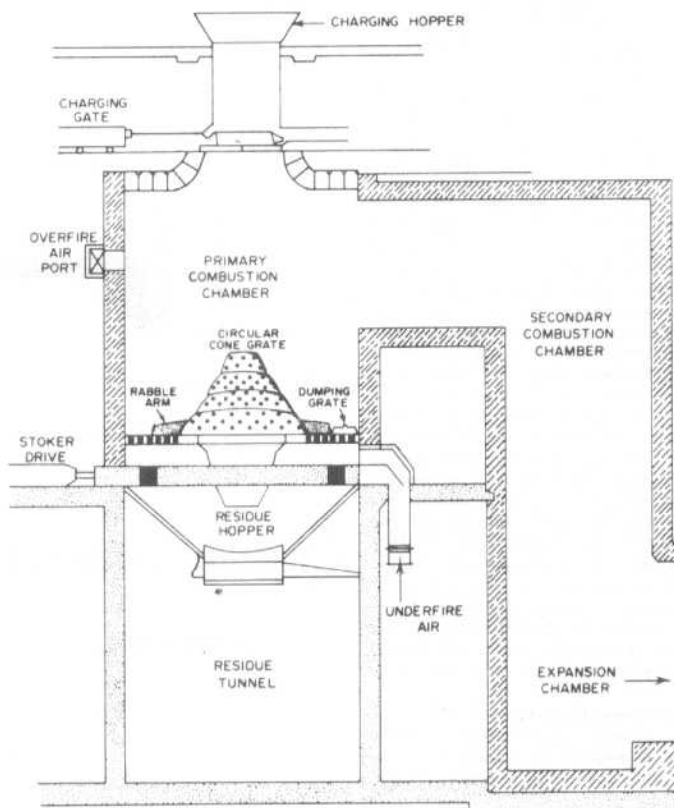

Fig. 3 Vertical circular furnace.

Governmental and Public INCINERATOR PLANTS

air is usually introduced to the upper portion of the circular chamber. A secondary combustion chamber is adjacent to the circular chamber. Many furnaces of this design are in operation.

The multicell rectangular type, also called the mutual assistance furnace, may be refractory lined or water cooled; it contains two or more cells set side-by-side, and each cell normally has rectangular grates (Fig. 4). Solid waste is usually charged through a door in the top of each cell. Generally, the cells of the furnace have a common secondary combustion chamber and share a residue disposal hopper.

The rectangular furnace is the most common form in recently constructed municipal incinerators (Fig. 5). Several grate systems are adaptable to this form. Commonly, two or more grates are arranged in tiers so that the moving solid waste is agitated as it drops from one level to the next level. Each furnace has only one charging chute.

A rotary kiln furnace consists of a slowly revolving inclined kiln that follows a rectangular furnace where drying and partial burning occur (Fig. 6). The partially burned waste is fed by the grates into the kiln where cascading action exposes unburned material for combustion. Final combustion of the combustible gases and suspended combustible particulates occurs in the mixing chamber beyond the kiln discharge. The residue falls from the end of the kiln into a quenching trough.

Grates and Stoking The grate system must transport the solid waste and residue through the furnace and, at the same time, promote combustion by adequate agitation and passage of underfire air. The degree and methods of agitation on the grates are important. The abrupt tumbling encountered when burning solid waste drops from one tier to another will promote combustion. Abrupt tumbling, however, may contribute to entrainment of excessive amounts of particulate matter in the gas stream. Continuous gentle agitation promotes combustion and limits particulate entrainment. Combustion is largely achieved by air passing through the waste bed from under the grate, but excessive amounts of underfire air contribute to particulate entrainment. Some inert materials, such as glass bottles and metal cans, aid combustion by increasing the porosity of the fuel bed. Conversely, inert materials inhibit combustion if the materials clog the grate openings. Mechanical grate systems must withstand high temperatures, thermal shock, abrasion, wedging, clogging, and heavy loads. Such severe operating conditions can result in misalignment of moving parts, bearing wear, and warping or cracking of castings.

For design purposes, the required grate area is approximated by dividing the pounds per hour of solid waste to be burned by the pounds per square foot per hour of solid waste the grates are capable of burning. Ordinarily, the design value for the grate loading will be between 50 and 70 lb per sq ft per hr. This design value depends mostly on type of solid waste and grate design, but it also depends on the other elements of the furnace. The grate loading is often expressed in Btu's per square foot per hour. An average rating of 300,000 Btu per sq ft grate per hr is often used as a design parameter.

Grate systems may be classified by function, such as drying grate, ignition grate, and combustion grate. Grates for solid waste incineration may also be classified by mechanical type.

Fig. 4 Multicell rectangular furnace.

Fig. 5 Rectangular furnace.

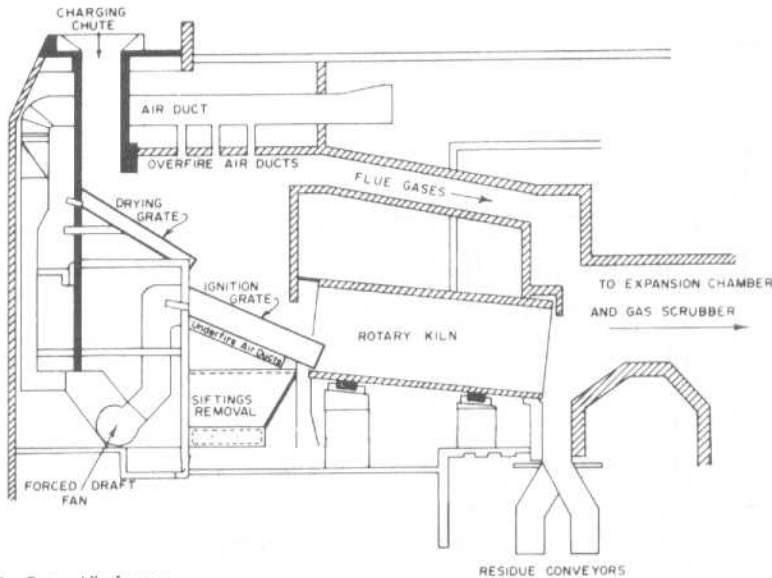

Fig. 6 Rotary kiln furnace.

Fig. 7 Traveling grates.

Fig. 8 Reciprocating grates.

Fig. 9 Rocking grates.

They include traveling, reciprocating, rocking, rotary kiln, circular, vibrating, oscillating, and reverse reciprocating grates; multiple rotating drums; rotating cones with arms; and variations or combinations of these types. In the United States, traveling, reciprocating, rocking rotary kiln, and circular grates are the most widely used.

Traveling grates are continuous, beltlike conveyors (Fig. 7). A single traveling grate does not promote agitation. Two or more grates at different elevations provide some agitation as the material drops from one level to the next.

In reciprocating grate systems, the grate sections are stacked like overlapping roof shingles (Fig. 8). Alternate grate sections slide back and forth while adjacent grate sections remain fixed. Like traveling grates, reciprocating grates may be arranged in multiple-level series providing additional agitation as the material drops from one grate to the next.

Rocking grates are arranged in rows across the width of the furnace, at right angles to solid waste flow. Alternate rows are mechanically pivoted or rocked to produce an upward and forward motion, thus advancing and agitating the solid waste (Fig. 9). Rocking grates have also been arranged in series.

The rotary kiln has a solid refractory surface and is commonly preceded by a reciprocating grate. The slow rotation of the kiln, which is inclined, causes the solid waste to move in a slowly cascading and forward motion.

The circular grate, in the vertical circular furnace, is commonly used in combination with a central rotating cone grate with extended rabble arms that agitate the fuel bed (Fig. 10).

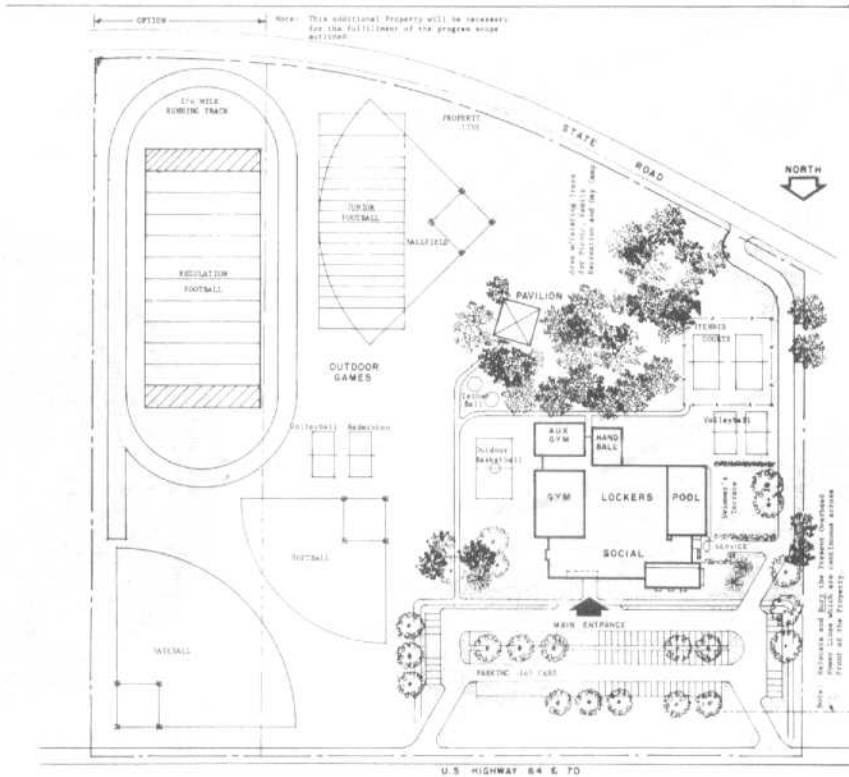

Fig. 2 Site plan. (National Council of the Young Men's Christian Association of U.S.A.)

By IRIS ALEX, AIA., Building Consultant, and GLADYS L. BROWN, Health, Physical Education, and Recreation Consultant

BUILDING SITE

The decision to build a new building or to undertake major renovations is the end result of a long process of study, analysis, planning, and fund-raising on the part of the local YWCA. The geographical location of a new facility is determined by community needs for the services to be offered.

The architect, it is hoped, will be involved in the selection of the site. The YWCA may have options on one or more parcels of empty land or land with existing structures on it. The following factors should be taken into account in choosing the site:

- *Proximity to public transportation and availability of parking facilities.* Depending on the locality, participants will arrive by bus or other available means of public transport or by private car. Since the building should attract all kinds of people, easy access to it is of prime importance. If the lot is not large enough to accommodate parking, there should be parking lots in the vicinity.

- *Size of site.* The site should be large enough to accommodate the proposed building, any possible future additions, on-site parking if required and desired, and outdoor activity space if this is included in the program.

- *Visibility.* The site should be easily seen and easy to find. There should be adequate road frontage for the building and for driveway entrances. Identifying signs should be visible from a distance.

When the building site is the property where the present YWCA building is located plus an adjacent lot, and the present building is to be demolished and replaced, careful consideration should be given to building the new structure in phases. Since the YWCA is a membership organization, a long interruption of services is detrimental. It is desirable to be able to carry on programs as long as possible and with as little disruption as possible in the old facilities while the new building is in the construction process. If the size of the site does not allow for phased construction, then the YWCA will have to move to temporary quarters.

GENERAL DESIGN PRINCIPLES

Thoughtful consideration should be given to the things the YWCA wishes to express through a building as well as to its adaptability and usefulness for the activities it is to house. The building should be a friendly place, attractive to different kinds of people. As a community investment, it should be designed for maximum use at minimum operating cost.

It should be designed so that people coming to it or just going by are aware that it is a busy place. Offices at the front of the building present a dark and lifeless appearance after office hours even though the rest of the building is teeming with activity. If it is evident from the outside that something is going on within, potential users will be more apt to investigate, and the contributor to the building or to the community fund will feel that he is helping to provide something that is really being used.

Maximum effectiveness in use of staff time

is essential. The element of control of the building should be given major consideration, so that staff on duty at a front desk can be alert to all people coming into or leaving the building. Additional exits for safety should be under the control of the person supervising the area during the periods when such exits are open. When space is provided for drop-in use, it should be located within the range of vision of either the front desk or a staff office during the time it is open. Program staff offices should be related to the activity areas to be supervised by the staff member. This gives opportunity for the supervision of the groups and for informal contacts with individuals before and after the activities.

Ease of maintenance is important, especially in small buildings not requiring the full-time services of an engineer or janitor. Heating should be as automatic as possible; mechanical equipment should permit operation with minimum attention and upkeep. In the long run it will save both money and man-hours if portable equipment is stored in a location related to its use, even though that may be more expensive to provide than a single storage room.

Since the building will be used by individuals of all ages—from toddlers to the infirm—details of construction should be designed so as to avoid offering temptation to the young. Everything from light switches to swimming pools should be viewed as having potential "attractive nuisance" qualities, and all possible safeguards should be provided. Rooms to be used for public meetings should be on the main floor, if possible, or otherwise readily accessible and located so as to reduce unnecessary traffic.

Interior construction and decoration should provide a colorful appearance and at the same time be durable and easy to maintain. Many materials now in use can make an attractive looking building and still meet the requirements of ease of maintenance. Furnishings can be both sturdy and attractive. The feminine touch can be achieved without wallpaper and ruffles or fragile furniture. Ingenuity in planning is required; it pays off both in long-term satisfaction and in economy of operation, so that the maximum possible amount of the yearly budget can go into staffing and otherwise supporting the program. (See Table 1.)

Another essential point is flexibility in use, with the amount of space for single-purpose use kept to the minimum. Additional storage for equipment for several groups, features that can be shut off from a room, or flooring and other elements in construction may increase the original cost of a single room but may greatly enhance its use. The standby cost of single-purpose rooms with limited use is even higher in the long run and is an extravagance during the life of the building. Wherever possible, the plan must permit flexibility so that later adaptations or modifications can be made without undue expense or waste.

MAIN ENTRANCE AND LOBBY

The front entrance should be inviting and accessible, avoiding steep steps and providing

sufficient platform space on the outside so that there is adequate clearance for doors that open out. Access for the handicapped must be provided. Doors should be sturdy but not too heavy. They should give some vision into the immediate lobby into which people enter.

Space inside the doors and on traffic lanes to other parts of the building should be sufficient and routed to cause a minimum of congestion at periods of peak use. Since the trend is away from huge lobbies and lounges, space actually needed for traffic should be achieved, insofar as possible, by planning for maximum use rather than for large areas. To avoid a "sitters' lounge," which tends to attract people who do not participate, only a limited lounge space should be planned, with the furnishings so arranged as to avoid interference with the traffic lanes. Wall space for displays and bulletin boards should be provided in the lobby.

The main entrance should be located carefully so that it is accessible to the street and to any parking area nearby, either one on the building site or a public lot in the neighborhood. If most participants arrive by car, it is important that they reach a main entrance by the shortest route from their cars. Very often, people find a side or rear door more conveniently located and enter the building by that means, thus complicating the control of traffic in the buildings. Have the lobby so arranged that the entrances from the street and from the parking area can easily be supervised from the reception desk. (See Fig. 1.)

RECEPTION DESK

The main front desk is both a key public relations contact and a control point for the entire building. It should be located so that people entering the building can find it quickly and so that the lobby and lounge are within the line of vision of the front desk staff.

The size of the main desk area will depend upon the volume of use and the number and kinds of services to be performed there. In a large building, especially when the front desk serves both an activities and a residence building and/or handles registration for activities involving large numbers of people, the counter should be large enough to permit two or more people to give service at the same time. It should be located so that traffic flows in one direction and people will not crowd in front of it, impede movement, slow down the service, or cut off the view.

Equipment should be planned and conveniently located for service at slack periods when a minimum staff is on duty and must be alert to what is going on in the lobby. If there are times when the person covering the counter must also operate the switchboard, it must be placed where she can save steps yet watch the lounge. Mailboxes, storage space, and file boxes or drawers for registration cards should be readily accessible. If, during their slack periods, the front office employees do any of the processes for large mailings, counter space should be provided away from the congestion of the regular working equipment. Provision should be made for the easy and safe handling

YWCA BUILDINGS

of cash and the issuing of receipts. An adjacent office is needed for the office supervisor and for jobs requiring concentration, such as record keeping or the counting of money. It is better to have the safe located in this office instead of in the main desk area. Sufficient storage space should be provided for supplies and equipment.

SPACE FOR BUSINESS AND ADMINISTRATION

Whether a business and purchasing office should be in the same area as the main desk and its related office space will depend on the size of the association and the number of people employed. In a small building, offices can be planned so that people doing several kinds of jobs can work nearby. Such a plan may include space for mimeographing and assembling, record keeping, bookkeeping, and other business or administrative tasks. In a large association with a sizable volume of business and a number of staff employed in the different kinds of operations, it will be better to locate the business and administrative offices elsewhere and in relation to each other so that as much of the main floor as possible can be kept free for activities. (See Fig. 2.)

Lavatory and coat storage space should be provided for the use of the staff in each total unit of offices.

Administrative offices should be provided for all administrative staff. The offices of the executive and any associates or assistants and the related clerical staff should be located so that they are accessible to the people who need to come to them but away from major activity areas. When possible, it is also advisable to have a separate office for the president, with a desk of her own and a telephone so that she can have privacy when she needs it. Sometimes this office can be used by other volunteers or staff. If the volume of work of the

treasurer is large, she needs an office or a desk in the business office.

Storage space is essential in administrative offices, and small offices uncluttered by needed materials or equipment can provide a better work setting than large floor spaces with makeshift storage arrangements. Offices of professional staff should not be arranged so that they give a sense of remoteness or inaccessibility. The offices for clerical staff should be adjacent to those of the professional staff with whom they work, so that they can work efficiently and screen unnecessary interruptions. If counseling or other individual services are offered, the office for that staff will need to be readily accessible to the hesitant or timid person and ensure a degree of privacy and freedom from interruptions. It is essential for a counselor to have an attractive private office for individual consultations. (See Fig. 3.)

The offices for the administration and management of the business and property of the association have been described at this point because of their relationship in a small building. Their exact location in larger buildings will vary according to other features. In any event, they will occupy a relatively small space as compared to that used for activities. The amount of space for administration and management may be increased where offices for metropolitan staff are housed in the central building. The total ratio of office to activities space should be studied in order to achieve maximum use of the building for program but also enough office space to serve the requirements of good administration.

SPACE FOR ACTIVITIES OR GROUP USE

The number and types of rooms to be included for program use will be determined by the space budget previously prepared by the YWCA building committee and the degree to

which multiple-purpose use can be made of each area.

Few buildings, even large ones, should have big rooms for single-purpose use. An auditorium with slanted floor and permanent seating is a luxury unless there is such heavy demand for it that it will actually be in use a large amount of the time.

The largest room for which an organization should make provision should be one that can house several kinds of activities and will be used to maximum capacity frequently enough to justify its inclusion in the plan. It is not advisable to consider providing for the largest group the association will want to assemble at any one time or even several times during a year. It is less costly to rent that kind of space elsewhere in the community for a limited number of events than to construct and maintain space that will in all or in part be standby space during most of the year.

The same principle applies to construction of health education facilities for competitive sports that are limited in the agency program and for which other community facilities are or should be made available.

On the other hand, a room for mass activities of several kinds can be justified, especially if it can be converted into two or more smaller rooms for other types of groups to use in between times.

A large multiple-purpose room in a building without a complete health and recreation department may have to be used for gym classes and also for mass activities. In order to make it useful for other things, there will be some limitations on the kinds of gymnasium programs and equipment that may be used. However, unless the primary use is for health education programs, it is probably too expensive to provide the special features required for competitive sports or other activities involving high-cost facilities that will not give maximum return on the investment.

TABLE 1 Recommended Finish Schedule for General Areas*†

Rooms	Floors										Walls							Ceilings				
	Resilient tile or sheet	Carpet (replaceable)	Carpet	Hard maple	Terrazzo (cement or epoxy)	Quarry tile	Ceramic tile	Dustproof concrete	Epoxy or cold-glazed cement coating on concrete block	Painted concrete block	Glazed tile or brick	Brick or other exterior wall	Wood paneling	Tackboard paneling (partial)	Vinyl wall covering	Steel and glass partition	Unfinished	Lay-in exposed-grid acoustic panels	Acoustic tile	Acoustic plaster	Plaster	Unfinished
Entrance vestibule	1								1		1										1	
Lobby, Lounge	2	1			1	1			1		1	1	1	1				2	1	1		
Corridors	1	1			1	2			1		1				1			2	1			
Offices	1	1											1	1	1	1		2	1			
Activity, class, club rooms	1	1							1	2			1	1	1			1	2			
Child care room	1	1							1	2			1	1	1			1	2			
Multipurpose room	2			1					1				1		1			1	2			
Crafts rooms	1					1		1	1	2	1				1			1	2		2	2
Storage	1							1		1												1
Service areas								1		1							1					1
Toilets							1				1				2					1		

* 1, 2 = Order of preference.

† Painted surfaces to be kept to minimum.

Adequate public toilet facilities for women and men should be provided in a location convenient for participants in activity areas. These should not be located too close to the front entrance and/or out of sight of the reception desk or some other control point.

Multipurpose Room

A room that can be used for dances, for informal mass activities, or as an auditorium and a banquet room can be designed to serve all those purposes satisfactorily if proper atten-

tion is given to the particular requirements of each.

For use as an auditorium, the size and type of stage and dressing rooms will depend upon whether the room will have frequent use for dramatic productions. For frequent use, a permanent stage with accessible dressing rooms is recommended. Dressing rooms can be designed for other uses provided there is adequate closet and storage space for each use.

Adjacent storage space must be provided for stage properties and surplus chairs in order to clear the room for dances and similar activi-

ties. A stage high enough to be seen from the back of a flat-floor auditorium will usually have room for some storage under it. Dollies which can easily be rolled in and out of such space save labor in setting up and clearing the room. If a portable stage is used, storage space must be provided.

If games or other activities may take place in the room, there should be adequate storage for that equipment. This may sound like a lot of storage, but it must be provided somewhere and more storage can result in more use of the available floor space for program. Proximity of storage to location of use can save time and effort for the maintenance staff and speed up the conversion of the space for different uses.

Checkrooms should be considered in relation to the large room and to other parts of the building. It is more economical to provide small checking areas located near activities space than to have one large checkroom requiring an attendant even at times of minimum use. Portable racks within sight of the groups or supervisor may be practical and can be moved into temporary checking areas when there is unusual demand. A checkroom should not be located in a heavy traffic area and should have a marked one-way traffic lane when a large group is to be served. A kitchen should be located for ease of service to the large room, directly connected with it or adjacent to it. Food should not be carried a great distance or across a hall or other space where people may be congregated or passing. Such functions will not necessitate a continuous or even frequent use for the kitchen and do not require elaborate refrigeration to carry over perishable foods. There should be a service entrance so that deliveries can be made and waste removed independently of the main lobby or heavy traffic lanes. It should be controlled when deliveries are being made. A buzzer connection should be installed to the main office facilities

Fig. 2 Oakland Branch, YWCA of Metropolitan Detroit, Michigan. Entrance area, offices, child care. Branch building. (O'Dell, Hewlett & Luckenbach, Architects.)

YWCA BUILDINGS

Fig. 3 YWCA of Greater Pittsburgh. Office floor, large metropolitan association. (Skidmore, Owings and Merrill, Architects.)

to call a janitor to take deliveries so that he will not have to waste his time waiting for them.

Storage for dishes can be provided by cupboards that open in the dining area or are adjacent to an opening for transfer to the dining area. The size and arrangement of other kitchen equipment will depend somewhat on the kind of service planned. If it is to be catering service, the total preparation of a meal may not be done on the premises. Sufficient heavy-duty equipment should be provided for normal use, but again it is not advisable to install all that would be needed for the unusual events.

Smaller Activity Rooms

Other rooms will be needed for small-group use and should be so arranged that they can be combined for different sized groups. A room that can be used for meetings of 150 to 200 people can be divided to form several small units. Good-quality acoustic folding partitions for dividing rooms can make the smaller units satisfactory for simultaneous use.

Entrance into each section of the room must be from a hallway, so that no group will be disturbed by people passing through and so that one or more sections need not serve as a passageway.

If several types of groups are to use the rooms, each group should have the equipment it requires, and the equipment adapted to several uses should be available as needed. A craft room has frequently been considered a single-purpose room, especially if, in addition to sinks, benches, and other usual equipment, the organization has a kiln or machinery for crafts. It is possible, however, to group these pieces of equipment at one or both ends of the room and shut off those areas with movable partitions that can be locked in place, thus converting the remaining area into a room for classes or other small meetings. Drying racks for craft products should be out of reach of the curious but accessible to the craftsmen. A well-organized display arrangement can offer

stimulation and new ideas to others. A similar plan can be used to convert activities space for use as a chapel or quiet room. An altar or other arrangement for worship that can be opened for use when the room becomes a chapel might be at one end.

The rooms used by several groups and the special-purpose areas should be grouped to facilitate supervision of the activities and provide a variety of programs close together. Meeting rooms, classrooms, craft and similar space should in general be located on one floor or on consecutive floors to permit ease of movement from one area to another and to limit the amount of elevator use (where there is one) and/or stair climbing.

Food service is needed in relation to program activities, and building plans should provide facilities for it. A kitchen that can be used for meals for large groups should be related to the area that will be used for such affairs. Kitchenettes should be provided to serve small groups, and if a residence is to be included in the plan, cooking facilities must be furnished for permanent residents. A snack bar adjacent to a drop-in lounge or recreation space may be provided.

Vending machines are often included in the program, and electrical and plumbing connections should be provided in locations where machines may be installed.

CHILD CARE FACILITIES

If a program is to be carried out for mothers of young children, a nursery with special lavatory facilities will be required. The proper standards are essential, both in the building arrangement and the supervision, and should meet local ordinances and health department requirements. If the space is to be used for other purposes, the special equipment will require storage space where it can be out of the way and properly protected. (See Figs. 1 and 2.)

Local ordinances dictate the space allotted per child, the maximum number of children per

room, and special facilities to be provided. An outdoor, enclosed play space adjacent to the indoor facilities is desirable.

HEALTH, PHYSICAL EDUCATION, AND RECREATION FACILITIES

If a YWCA is planning to include HPER facilities, particularly a swimming pool in new building plans, or to add these facilities to an already existing building, meticulous research and care must go into choosing construction methods, mechanical, electrical, and filtration systems, finishing materials, and into designing the area for the best traffic flow and use of space. (See Figs. 4 to 6.)

The operating costs of HPER facilities are rarely subsidized by the local community chest agency, and the YWCA must pay all operating and maintenance costs for these facilities out of the income from classes and rentals. Since construction costs are so high for these facilities, the design must provide for the maximum utilization of teaching-staff time and ease of maintenance and operation by the custodial staff.

There should be an easy flow of traffic from the main lobby. Having the swimming pool visible from the lobby will attract participants. Spectator space in the natatorium is desirable if the budget allows for it.

It is preferable to have the entire HPER unit on the ground floor. If this is not possible, the locker rooms and swimming pool must be on one level, and the gymnasium or multipurpose room, dance and exercise studios can be located on a different floor but with a means of access directly from the HPER lobby area. It is important to avoid cross traffic of participants in gym attire with other traffic in the main lobby.

The HPER facilities should be so situated in the building that they can be open for rental by outside groups when other parts of the building are closed.

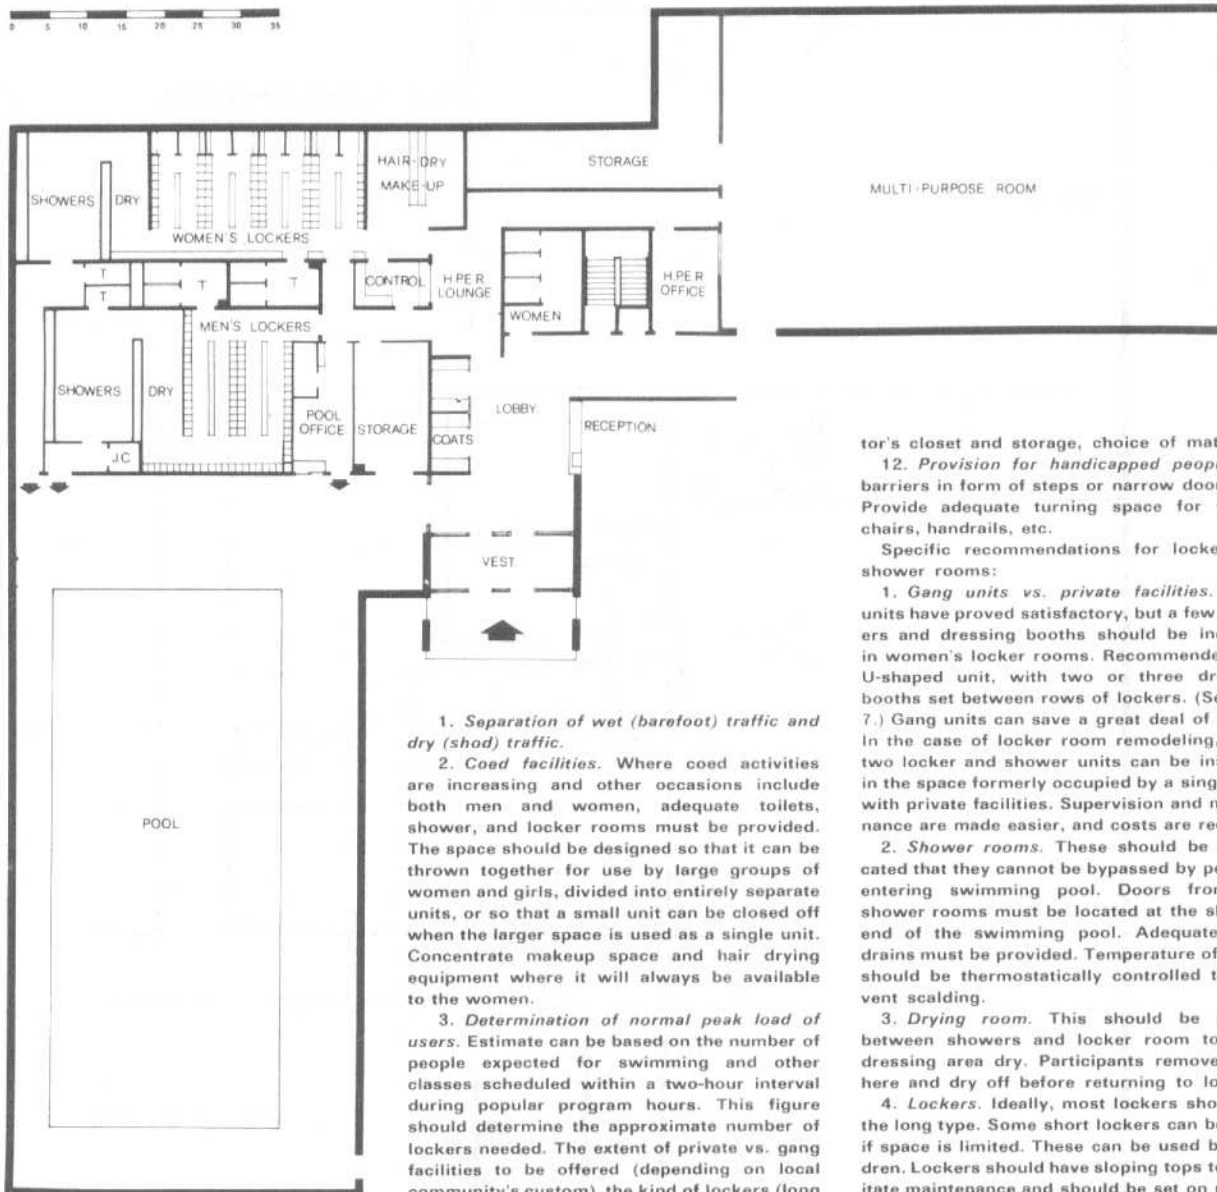

Fig. 4 Bangor, Maine, YWCA, HPER addition.
(Higgins, Webster and Partners, Architects.)

Elements in a Total HPER Unit

Lobby Lounge

A separate lounge adjacent to the locker rooms should be provided for HPER participants. A control office with a counter from which an attendant may dispense locker keys and towels, keep records, etc., should open into this room. Doors to locker rooms should be within sight of the attendant. Lounge furniture, bulletin boards, and vending machines should be provided. Access to gymnasium or other small exercise rooms should be through this space. Participants in gym attire can wait here for classes in order to relieve the occupant load in the locker rooms.

Ideally, the locker room entrances can be closed off and the space used as a social lounge during recreational and social programs.

Locker and Shower Rooms Important considerations in locker-room design include the following:

1. *Separation of wet (barefoot) traffic and dry (shod) traffic.*

2. *Cood facilities.* Where coed activities are increasing and other occasions include both men and women, adequate toilets, shower, and locker rooms must be provided. The space should be designed so that it can be thrown together for use by large groups of women and girls, divided into entirely separate units, or so that a small unit can be closed off when the larger space is used as a single unit. Concentrate makeup space and hair drying equipment where it will always be available to the women.

3. *Determination of normal peak load of users.* Estimate can be based on the number of people expected for swimming and other classes scheduled within a two-hour interval during popular program hours. This figure should determine the approximate number of lockers needed. The extent of private vs. gang facilities to be offered (depending on local community's custom), the kind of lockers (long or short), methods of checking and control, and the number of showers and toilets required by state health codes and good practice also figure in determining the size of the locker facilities. Adequate dressing and circulation space are important. Ten to fifteen sq ft per person should be allowed.

4. *Safety of program participants.*

5. *Provision for storage of coats and bulky belongings.* This is a factor in locker size. Lockers should be large enough to accommodate a dress hanger. If necessary, coats can be stored on racks under the supervision of the attendant.

6. *Protection of participants' belongings.*

7. *Supervision of locker rooms.* This is especially important if there is a heavy emphasis on children's program.

8. *Method of control and dispensing keys, towels, etc., and checking valuables.* Possible need for washing machine and dryer.

9. *Attractiveness of area.* Layout, materials, colors, lighting.

10. *Comfort of participants.* Temperature, humidity, acoustics, good traffic patterns, adequate space.

11. *Ease of maintenance.* Well-located jani-

tor's closet and storage, choice of materials.

12. *Provision for handicapped people.* No barriers in form of steps or narrow doorways. Provide adequate turning space for wheelchairs, handrails, etc.

Specific recommendations for locker and shower rooms:

1. *Gang units vs. private facilities.* Gang units have proved satisfactory, but a few showers and dressing booths should be included in women's locker rooms. Recommended is a U-shaped unit, with two or three dressing booths set between rows of lockers. (See Fig. 7.) Gang units can save a great deal of space. In the case of locker room remodeling, often two locker and shower units can be installed in the space formerly occupied by a single unit with private facilities. Supervision and maintenance are made easier, and costs are reduced.

2. *Shower rooms.* These should be so located that they cannot be bypassed by persons entering swimming pool. Doors from the shower rooms must be located at the shallow end of the swimming pool. Adequate floor drains must be provided. Temperature of water should be thermostatically controlled to prevent scalding.

3. *Drying room.* This should be placed between showers and locker room to keep dressing area dry. Participants remove suits here and dry off before returning to lockers.

4. *Lockers.* Ideally, most lockers should be the long type. Some short lockers can be used if space is limited. These can be used by children. Lockers should have sloping tops to facilitate maintenance and should be set on raised, coved bases. Lockers finished in bright colors are an excellent means of providing a cheerful atmosphere. Benches can either be floor-supported between rows of lockers or cantilevered from the base below the lockers.

5. *Toilet facilities.* Two sets of toilet facilities are needed, one "wet" and one "dry." The wet unit can consist of a single toilet without washbasin located off the shower room. The user reshows before going back to the swimming pool. The dry unit is located near the locker room entrance and makeup area and contains washbasins in addition to toilets. Toilets should be wall-hung and partitions ceiling-hung to facilitate maintenance.

6. *Makeup area.* This is an essential area and should be located out of the main traffic flow. Adequate space should be provided to accommodate large groups. Provide deep shelves at standing height and adequate mirror area. This should be located in the women's locker room but should also be available to the second locker room when both are used by women and girls.

7. *Hair dryers.* These should be located adjacent to the makeup area. Automatic, wall-hung dryers are recommended and should be set at

Fig. 5 Orange, New Jersey, YWCA, HPER facilities. (Emil Schmidlin, Architect.)

suitable heights for girls and women. Some hair dryers should be placed in the men's locker room. Do not locate hair dryers near the shower rooms. Hair clogs the floor drains, and participants should dress before using hair dryers.

8. *Materials used in locker-room construction.* The ideal floor material is nonslip ceramic mosaic tile. Unfinished concrete usually encourages fungus growth and attracts dirt. If the budget is too restricted for ceramic tile throughout the locker area, it should be used in the shower and drying rooms, and a good concrete sealer should be used for the dry dressing areas.

All floors must pitch to adequate drains, and hose bibbs should be provided. See sched-

ule for recommended floor, wall, and ceiling finishes. (See Table 2.)

9. *Lighting, Heating, Ventilating.* Lighting should be in the form of recessed, vaporproof fixtures. Illumination should be evenly distributed over the entire area, with fixtures located over dressing spaces between rows of lockers. The recommended footcandle level is 30. Provide concentrated and flattering lighting at the makeup area.

In designing the heating, ventilating, and air conditioning system, the locker room and shower areas humidity control is a prime factor. This area should be zoned separately. Too high a velocity of air is chilling to the wet skin. The shower and locker room temperature should be about 80°.

Offices The number of offices required reflects the size and scope of the program. At minimum, the following are required:

1. *Director's office.* This office should be located either off the HPER lounge-lobby or off an adjacent corridor. This office should be easily accessible to the public and closely related to the HPER unit. When a swimming pool is not included in the HPER unit, a staff dressing room and shower should be connected to this office.

2. *Pool office.* A second office is needed when a pool is included. This office opens off the HPER lounge or locker-room complex and has a door opening directly onto the pool deck. This office, which should have a large sliding glass window for supervision of the

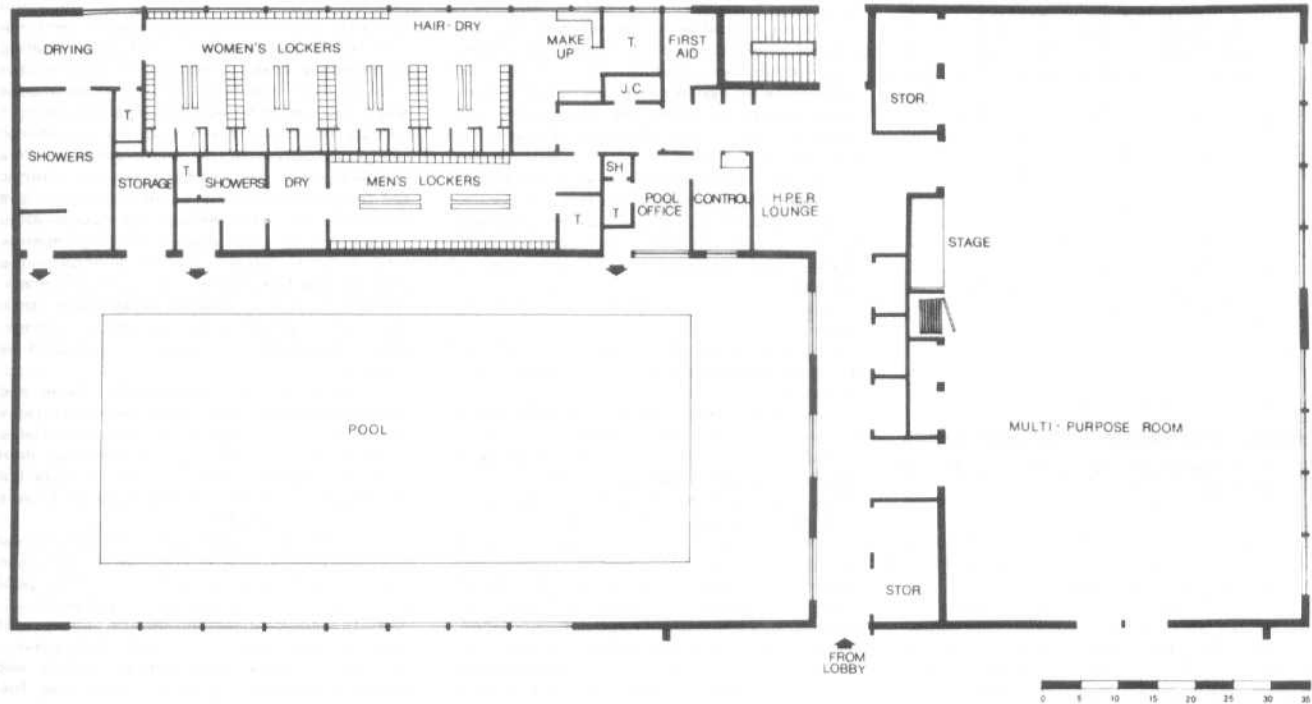

Fig. 6 Greenville, South Carolina, YWCA, HPER facilities. (Charles Potter, Jr. — Alison Lee, Architects.)

pool, contains controls for the natatorium and underwater lights and sound system, first-aid equipment, a telephone, teaching aids, and audio equipment. There should be a staff dressing and shower room opening off this room. The pool office should be large enough to accommodate a first-aid cot.

3. Control office for locker-room attendant, previously described.

Gymnasium or Multipurpose Room Previously determined budget and program factors dictate whether there will be a regulation gymnasium or a multipurpose room. Very few YWCAs can

afford the luxury of two large rooms, so that a multipurpose room usually serves for physical activities as well as large meeting, social, and food service events. The floor must be suitable for all uses and preferably should be wood. Court markings and floor sockets should be provided as required.

TABLE 2 Recommended Finish Schedule for HPER Facilities*†

Rooms	Floors								Walls						Ceilings							
	Cushion-edge nonslip ceramic tile	Abrasive Terrazzo	Trowel-on epoxy coating	Resilient tile or sheet	Hard maple	Synthetic gym flooring	Carpeting	Dustproof concrete	Ceramic tile	Glazed block or brick	Epoxy or cold-glazed cement coating on concrete block	Wood paneling	Painted concrete block	Vinyl wall covering	Unfinished	Perforated metal panels	Perforated asbestos-cement panels	Kiln-fired, waterproof mineral-fiber tile	Lay-in exposed-grid acoustic panels	Glass-fiber acoustic units	Plaster	Unfinished
Natatorium	1	2							1	1	2					1	1	1		1		
Shower rooms	1	2							1	1						1		1			1	
Locker rooms	1	2	3					3	1	1	1		2					1	1			
Toilets	1								1	1	2			3					2		1	
Offices, lounge				1			1				1	1	2	1					1			
Gymnasium					1	2				1		1	2						1			
Multipurpose room				2	1						1	1		1					1			
Dance, exercise rooms					1						1	1	2						1			
Fitness studio				2			1					1	2	1					1		2	
Storage								1							1							1

*1, 2, 3 = Order of preference.

†Painted surfaces to be kept to minimum.

Fig. 7 Recommended U-shaped unit of lockers and dressing booths.

Collapsible bleachers, a viewing balcony, and a portable or permanent stage may be included in the program and budget.

Consult *Planning Areas and Facilities for Health, Physical Education, and Recreation*, published by the American Association for Health, Physical Education, and Recreation, 1201 Sixteenth Street, N.W., Washington, D.C. 20036, and available on order from the YWCA National Board, 600 Lexington Avenue, New York, N.Y. 10022. This volume gives regulation floor areas, court markings, ceiling heights, and other pertinent design data.

Provide as much flat, clear wall space as possible. Avoid column and other projections inside the room. Lighting fixtures should be shatterproof, and an exposed grid, lay-in acoustic board ceiling is the most practical, since panels can be easily replaced in case of damage. Separate storage rooms adequate for gym equipment and for chairs and tables should be provided. If the program calls for the large room to be divided, provide an acoustically rated folding partition. Adequate power outlets should be provided. Other possible program requirements are sound systems, bulletin boards, projection screens, etc.

Smaller Activity Rooms Some physical education activities call for smaller rooms: corrective exercise and dance classes, for example. These rooms should have wood floors and mirrors. Ballet bars and other required apparatus should be included. If there is a fitness studio in the program, provide adequate space for all contemplated equipment. A carpeted floor may be desirable.

Natorium The natatorium is a large, clear-span room, with adequate heating, ventilating, and humidity controls, which houses an indoor swimming pool. Sufficient width must be provided for adequate deck space around the pool.

The interior walls of the natatorium should be flush. Avoid column projections and recessed areas, including entrances from locker rooms and offices. The lifeguard on duty must be able to see the entire space. The exterior walls and roof should be well insulated to prevent condensation.

The YWCA swimming program is primarily intended for teaching, with recreation secondary. Both functions must be income-producing, and maintenance and operating costs must be kept low.

It is often tempting to envision an indoor-outdoor pool situation, but the necessary provisions for this kind of design feature are costly

to construct and keep in repair, whether they are sliding glazed walls, movable roofs, pressurized enclosures, or a battery of hinged, glazed doors. The outdoor setting is not used sufficiently in YWCA programs in most parts of the country to justify the cost. Sunbathing space is not income-producing, and added staff supervision is required.

The inclusion of any windows is not recommended, since sunlight reflects on the water surface, making it difficult for the lifeguards to see the swimmers. It also causes algae growth and consumes large quantities of chlorine.

Important considerations in natatorium design:

1. **Ceiling height.** A minimum height of 15 ft must be maintained over a 1-meter diving board.

2. **Materials.** All materials used in the natatorium must be moisture- and chemical-resistant. A schedule of recommended materials is shown. Any metal doors, trim, railings, etc. should be stainless steel. Any other metal will require too much maintenance.

3. **Ventilation.** Controlling the humidity in the natatorium is essential. Introducing dry, heated air and removing moist air should produce a comfortable environment. Temperature must be kept constant and at a minimum of 80° for swimmers' comfort. When spectators are present for a competitive event, the temperature can be lowered. Air velocity should be kept low to avoid chilling wet skin. A flat ceiling surface is desirable to allow air to move freely.

4. **Adequate acoustic control.** This is essential for a teaching program. An acoustic ceiling of moisture-resistant material can be supplemented by wall-mounted acoustic units.

5. **Good lighting.** Light fixtures should be located over the pool deck only for easy relamping and should provide a minimum uniform lighting level of 60 footcandles. The light source should be diffused to avoid glare on the water surface. An emergency lighting system must be provided.

6. **Spectator space.** Desirable for teaching and for special events. Spectator space must be separated from the pool deck by a low wall. The spectator entrance should be controlled from the reception desk. It is preferable to have the spectator space at or slightly above the deck level rather than at balcony height.

7. **Miscellaneous provisions.** An adequate storage room is required for instruction and other pool equipment such as lane markers, starter blocks, a canoe if called for in the program, etc. Maintenance equipment should be stored separately.

Hot and cold recessed hose bibbs, a drinking fountain, a clock, and an adequate number of power outlets should be provided. Include hooks or inserts on the upper walls for displays and decorations. Provide means of hanging rescue equipment (pole and ring buoys) so that it can be reached when needed.

Swimming Pool Important considerations in swimming pool design:

1. Conformance to state or local regulatory agency regulations. Submission of plans and specifications for approval.

2. Careful study of soil mechanics, results of test borings to determine best pool shell and foundation construction, drainage, need for hydrostatic relief valves, etc.

3. Thorough inquiry and research into YWCA's proposed program use of swimming pool. Requirements for instructional, recreational, and competitive uses of a pool are sometimes in conflict, and program emphasis will be a decisive factor in choice of size, water

depth, and overflow system. The pool must be easily accessible to handicapped persons.

4. Initial construction costs and ongoing maintenance costs. Construction savings that will require extensive future maintenance and repairs must be avoided. There is no comparable substitute for a properly engineered reinforced-concrete pool shell. Some savings can be made in finishes by restricting ceramic tile to a minimum area at the water line and plastering the rest of the tank. By incorporating adequate surge tank area, either in a separate tank or in an integral trench, savings in the heating and filtering of water can be made. Architects should avoid inexpensive pool "packages" which seem to afford savings. Often much of the equipment included is inferior.

Count on your combined architectural and engineering experience or engage the services of a qualified pool engineer to design a suitable installation. The National Swimming Pool Institute in Washington, D.C. may be contacted for suggested names of qualified engineers throughout the country.

If the YWCA does not have the funds to build a well-designed pool of the size desired it is advisable to cut down the size of the pool rather than sacrifice construction quality.

5. Thorough investigation of source of potable water supply (for sufficient volume and for chemical composition), waste and sewer connections, power supply and fuel supply in the vicinity.

6. Read and follow applicable suggestions in the following reference materials:

a. *Suggested Minimum Standards for Residential and Public Swimming Pools*, National Swimming Pool Institute, 2000 K Street, Washington, D.C. 20006.

b. State or local health codes covering public swimming pools.

c. *Swimming Pools, A Guide to their Planning, Design and Operation*. Council for National Cooperation in Aquatics. Hoffman Publications, Inc., Sunrise Professional Building, Fort Lauderdale, Florida 33304, 1969.

d. *Planning Areas and Facilities for Health, Physical Education and Recreation*, previously cited.

Specific Recommendations for Pool Design

1. **Size and shape.** A rectangular pool with vertical side walls is recommended, with deep water at one end and shallow water at the other.

Pool size will be determined by program needs. If schools and other agencies will be using the facility, cooperative planning is necessary.

Standard pool sizes (in feet):

60	by 25
60	by 30
75	by 25
75	by 30
75	by 35
75	by 42*
82.5	by 42*

Competitive requirements:

For recognized competition, a 75-ft pool is essential. (Actual length is 75 ft 1 in.) Swimming lanes should be 7 ft wide. A minimum of four lanes is needed, with 1 ft extra on outside lanes. If the YWCA will be building the only pool in the community, it may be necessary to meet competitive requirements. If a heavy

*Not generally recommended for YWCAs.

instruction program is anticipated, especially using the station teaching method with several teachers at the same time and large classes, the 75-ft pool with a large shallow water area is desirable.

2. *Depth.* Minimum depth of water allowed is 3 ft. Recommended shallow depth is 3 ft 6 in. This is required for a competitive pool. Approximately 60 to 65 percent of the pool area should contain water less than 5 ft deep. The slope of the shallow water area must be gradual. In depths under 5 ft, it should not slope more than 1 ft in 15.

Minimum deep water depth is 9 ft for a 1-meter diving board, although some state codes require a 10-ft minimum. Recommended pool bottom contours are shown in the National Swimming Pool Institute Standards. The deepest point in the pool should be under the plummet line from the end of the diving board. For good water circulation, the pool bottom should rise gradually from this point to the deep end of the pool.

3. *Pool construction.* Any choice of material for construction or finishing that requires frequent repair, refinishing, or painting is not economical. Certified boring logs should be obtained and expertly interpreted so that the appropriate shell construction can be determined. Poured reinforced concrete is preferred. Adequately reinforced pneumatically applied concrete has been used, but the curved bottom contour interferes with full use of the pool for teaching. Metal shell construction requires constant repainting, which causes disruption to teaching schedules and subsequent loss of income.

4. *Pool tank finishes.* Ceramic tile remains the classical permanent swimming pool finish. Tile should be vitreous square-edged tile to permit smooth tile grout. White tile should be used within the tank, with required lane and target markings in black. Properly filtered water is blue and looks best in a white tank. If the use of tile must be restricted, it can be installed in a 1-ft-deep band along the long sides and extend 3 ft 6 in. down at the ends. The rest of the tank can be plastered. A white cement plaster with a "marble dust" finish should last from four to eight years. Pool markings can be delineated by having lines cut or by setting tile strips before plastering.

Pool markings must be carefully indicated on the detail drawings. Required markings for competitive swimming can be found in *Swimming Pools, A Guide to their Planning, Design and Operation*, previously cited. Recessed cup-type anchors and inserts for lifelines and lane dividers must be provided for.

5. *Pool ladders and entrance steps.* Ladders should be recessed in side walls only, adjacent to deep and shallow ends. If deck space and budget permit, a short flight of steps leading into the shallow end should be incorporated into the design.

6. *Overflow systems.* There is a wide choice of overflow systems: fully recessed or semi-recessed gutters, roll-out, rim-flow, or deck-level systems; surface skimmers; and prefabricated steel semi-recessed gutters.

Cost factors influence the choice. For example, a fully recessed tile gutter is the most expensive to install, while a deck-level installation with large coping stones will have a minimum cost both in construction and associated piping.

Proposed program use influences the choice. Deck-level, rim-flow, or roll-out systems offer ideal conditions for teaching and recreation but are not ideal for competition, where the ends of the pool must be defined. This problem can be solved by setting up temporary turning boards for competitive events.

An important element in the general hydraulic performance of the system is adequate surge tank capacity. The function of a surge tank is to provide storage area for large volumes of overflow or gutter water that are likely to accumulate at rates faster than the circulating pump can accommodate. This capacity is required to maintain a continuous skimming of the overflow perimeter edge for proper sanitary conditions in the pool. The tank can be a separate chamber of concrete or steel, or it can be integrally accommodated (as in the trench of the deck-level and rim-flow systems). The National Swimming Pool Institute recommends a minimum of $\frac{1}{2}$ gal of water for every square foot of pool surface.

Whatever overflow system is used, the coping or edge must be installed dead level and must provide a comfortable handhold for swimmers. The number of drains and the size of the piping from the overflow system must be adequate to prevent flooding of the gutters, which would interfere with the skimming of the surface water.

A comparison and evaluation of overflow systems follow:

a. *Fully recessed gutter.* No drawing is shown. This is an old-fashioned system with many drawbacks and is not recommended for YWCA pools. It is the most expensive to build, difficult to clean, and contrary to good pool operation.

b. *Semirecessed gutter.* (See Fig. 8.) Similar to fully recessed, but water level is closer to deck and gutter is easier to clean. System must be piped to surge tank.

Advantages	Disadvantages
Provides visible pool edge for competition	Water level 5 or 6 in. below deck. Difficult to climb out of pool
Cuts down surface roughness when gutters are flooded	Some cleaning difficulty
Water surface closer to deck than in fully recessed	Requires pipe tunnel for access
	Narrow edge of gutter lip provides precarious footing for diving off edge

Recommendations: Acceptable for YWCA pools.

c. *Roll out.* (Fig. 9) Basically a deck-level installation. Drains are located either in horizontal portion of shallow trench or in corner.

Advantages	Disadvantages
Comfortable pool use and egress	Decks may flood if adequate number of drains are not provided
Ideal for teaching and recreation	Pool edge not visible for competition. Temporary turning boards can be used
Gives beginner swimmers feeling of security by allowing wide visibility	Requires pipe tunnel for access
Easy cleaning	
Low construction costs	

Recommendation: Excellent for YWCA pools.

d. *Deck-level or rimflow system.* (Fig. 10.) These two systems have many similarities but they differ in their hydraulic characteristics. The *deck-level* installation has side inlets and a bottom main drain. The integral trench serves as surge capacity for surface skimming, and supply piping can be run in the trench. The *rimflow* installation has bottom inlets and the integral trench serves as the main drain. All the pool water is drawn over the edges. Both systems incorporate a precast coping and precast concrete slotted trench cover.

Advantages	Disadvantages
Trench serves as integral surge tank	Deck can flood if not properly pitched
Minimum construction costs	Pool edge not visible for competition. Temporary turning boards can be used
No pipe tunnel needed	Care must be taken in choosing cleaning materials for deck since some deck water enters pool recirculation system
Comfortable pool use and egress	Bottom inlets in rimflow system are inaccessible for servicing
Ideal for teaching and recreation	
Gives beginner swimmers feeling of security	
Easy cleaning	

Recommendation: Excellent for YWCA pools.

e. *Surface skimmers.* No drawing is shown. This system consists of container devices set in the top of the pool wall. The skimmers operate by suction of the pool pump. There is no surge tank required, and the water is constantly skimmed by movable weirs. Skimmers are not approved by all state boards of health. The disadvantages are the continuing expense and nuisance of maintaining the movable weirs and the fact that skimmers do not eliminate surface turbulence in large pools. Surface skimmers are suitable for very small pools only. They are not recommended for large YWCA pools.

f. *Prefabricated stainless steel recessed gutter.* No drawing is shown. This system is usually part of a commercial "package." The disadvantages are numerous: skimmer weirs needing manual adjustments several times a day, water-line inlets that disturb swimmers in end lanes, and exposed rings for lane and life lines among them. The main advantages are that a pipe tunnel is not required, and the manufacturer substitutes a large diameter return pipe for a surge tank. This system is not recommended for YWCA pools.

7. *Underwater lights.* Lights can be either wet-niche or dry-niche type. Dry-niche lights require a pipe tunnel or manhole for servicing. Wet-niche lights are reached from inside the pool and the fixture brought up to the deck for relamping. Follow requirements of Article 680 in the National Electrical Code.

Underwater lights are desirable for safety and for synchronized swimming programs.

Fig. 8 Semirecessed gutter.

pool shows, and pageants. An acceptable lighting level is 1 watt per square foot of pool area.

Lights should be located in side walls only, and not directly opposite each other. Depth below water line should be at least 3 ft in the shallow area, and about 6 ft 8 in. in the diving well.

If the budget does not allow for complete installation of lights, provide conduit, junction boxes, wall niches, and other provision for future installation. Controls for underwater lights must be located in the pool office.

8. *Underwater speakers* are useful for coaching and for synchronized swimming.

9. *Decks.* Decks must completely surround the pool. For side decks, the minimum width is 5 ft, but the side used for instruction should be wider. Decks at both ends should be 13 to 15 ft wide. Decks should have nonslip surfaces, preferably of cushion edge mosaic ceramic tile 1 by 1 in. or 2 by 2 in. in size. Depth and distance markings should be in a contrasting color. Deck surface must be properly pitched to an adequate number of drains. It is important to pitch decks so that water splashed on the decks does not return to the pool. Provide corrosion proof anchors and inserts for deck equipment.

10. *Deck equipment.* Deck equipment may include diving boards (no higher than 1 meter recommended), lifeguard chair, starter blocks, and a hydraulic lift for the handicapped. Lifeguard chairs are essential for large pools as specified in state codes. Some form of vacuum cleaner must be provided. Recommended are automated pool-bottom cleaners that require only a power outlet. This kind of cleaner cuts down considerably on maintenance time.

An adequate number of recessed hot and cold hose bibbs should be provided to allow any part of the pool and natatorium to be reached with a 75-ft hose.

11. *Water circulation and filtration systems.* There are three interrelated and interacting systems required to clarify and disinfect water in the swimming pools:

- Recirculation and distribution of water
- Removal of particles by filtration
- Feeding chemicals for disinfection and control of pH

Pool water should be pumped, filtered, chemically treated, heated, and circulated continuously at a minimum turnover rate of eight hours—six hours if the pool is heavily used. Water is introduced into the pool through inlets (normally located on the sides, although the rimflow system has bottom inlets), dispersed uniformly, and removed through main bottom drains located at the deepest point of the pool. (In the rimflow system, all water is drained

over the pool edges.) Supplementary drainage is by means of the overflow system which continuously skims the surface water. The highest degree of contamination is found at or just below the water surface.

A note of caution about main bottom drains—the grating must be heavy enough so that swimmers can't remove it, and the openings must be so small that divers' fingers can't be caught in them.

Brief description of interrelated systems: Return water is piped from main drain line and surge tank through hair and lint catcher, pumped through a flowmeter to the filters. (Note: If vacuum-type diatomaceous earth filter is used, this kind of filter precedes the hair and lint catcher on the suction side of the pump. Granular media (sand and gravel) filters and pressure diatomaceous earth filters are on the pressure side of the pump.) Chemicals are introduced into the water through mechanical feeders. Then the water is heated and returned to the pool through the inlets. All equipment and piping must be sized for the recommended turnover rate.

Some recommendations:

Pumps. Pumps are preferably located below the water line, or self-priming pumps must be specified. Dual pumps should be provided, in case of breakdown.

Filters. The most commonly used filters are either pressure granular media filters (sand and gravel or anthracite) or pressure or vacuum diatomaceous earth filters. A comparison follows:

- *Pressure granular media filters:*
High initial costs, low operating costs. Require little maintenance and no replacement of filter medium.
Backwashing is simple but requires a large volume of water.
Require large floor area. Filters are usually installed in batteries of three or four which enables one to be backwashed while the others operate. (Smaller high-rate sand filters are on the market. These have been installed in a few YWCA pools recently and have proved satisfactory.)
Traditional granular media filters are recommended for YWCAs because of their low maintenance costs and simple operation.
- *Diatomaceous earth filters, pressure or vacuum:*
Low initial costs, high operating costs. Require extensive care. Filter medium must be replaced each time filter is backwashed.

Possibility of medium entering pool and clouding water if not skillfully handled. Requires less water to backwash.

Diatomaceous earth does not remove some water discoloration, specifically if the water supply contains iron.

Recommended for YWCAs only if a skilled pool maintenance man is available.

Water treatment. Chlorine is the most widely accepted agent for water purification. While bromine and iodine are being used in some areas, they are much more costly and have not been given broad approval by public health authorities.

Chlorine is available in gas form, delivered in sealed tanks; as calcium hypochlorite in powder form; or as sodium hypochlorite in liquid form. Whichever form is used, application through a mechanical feeder is required. The feeder must be capable of supplying 1 lb of chlorine per eight hours for each 10,000 gal of pool water.

Chlorine gas is dangerous to handle, although less costly than other types.

Calcium hypochlorite is safer and easier to handle but is still combustible. This type is recommended for YWCA pools.

Sodium hypochlorite delivered in jars is bulky and hard to handle. The chemical breaks down under warm conditions.

All the above chemicals lower the pH factor in the water, so that an acid neutralizing agent like soda ash must be added.

Delivery, storage, and handling of pool chemicals must be taken into account when designing and locating the filter room. When the filter room is below grade, a sidewalk elevator can be provided or some means of lowering deliveries of supplies. Adequately sized doors and areaways facilitate delivery and replacement of bulky equipment. The pool filter room should have good ventilation and a water supply.

SERVICE FACILITIES

Provide space for maintenance equipment and storage, janitor's closets in strategic locations, maintenance workers' dressing rooms, office space for the chief maintenance man, and unloading and receiving facilities.

Provide public telephones and drinking fountains in convenient locations.

MECHANICAL EQUIPMENT

The proposed mechanical systems for the building must be presented and explained to the building committee and board of directors. The anticipated capability of the maintenance staff is a factor to consider in the choice of systems. Automatic controls should be considered in order to cut down on maintenance time.

If there are not sufficient funds available to complete air-conditioning systems, for example, install roughing provisions for future completion which will cause the least disruption and renovation when funds can be raised to complete the installation. Air conditioning is recommended for most YWCA buildings so that facilities can be used to their maximum effectiveness all year long.

SPECIAL FACILITIES

Two special features may or may not be included in the building plans. One is food service in the form of a cafeteria or coffee shop, and the other is residence (Figs. 11-13).

Fig. 9 Roll out.

Fig. 10 Rimflow or deck level system.

Food Service

Cafeterias serving individual meals at cost are features associated with the YWCA for many years. Originally, food service was for the benefit of women and girls at a time when public food service was not readily available. The cafeteria idea was developed by the YWCA in many communities in order to provide whole-

some food at prices employed women and girls could afford, and in a suitable atmosphere. Subsidy of such a feature was accepted as long as it was recognized as a necessary service for the girls and women for whom the organization assumed responsibility. The success of the idea and the quality and price of the food attracted other clientele, whose patronage tended to decrease the subsidy.

The situation has changed over the years in most communities where reasonably priced meals are available in restaurants and other eating places, to the point where the YWCA may no longer provide a unique service. Often the food service operation in the YWCA now is unable to compete and again must be subsidized or closed. Private operators rightly question the use of contributors' money to subsidize a competitor and, in addition, feel that the YWCA has an unfair advantage because of its tax-free status. In some instances the association has rendered itself liable to property tax because of its food service.

The inclusion of an extensive food service operation in a new or remodeled building should be the result of an established program need for residents or for members, staff, and volunteers engaged in varied YWCA programs. Among the factors to consider in reaching the decision to include such facilities are the location of the building in relation to nearby eating places, the size of the building, the kinds of programs offered, and the numbers of people present in the building during meal hours.

The food service facilities noted earlier—a kitchen to serve group meals, kitchenette units, vending machines, and cooking facilities for residents—may suffice for food needs in a small building. In a large building, it may prove economically feasible to install more extensive facilities if the need is present.

Governmental and Public
YWCA BUILDINGS

Fig. 12 Charlotte, North Carolina, YWCA, residence floor. (J. N. Pease Associates, Architects.)

Fig. 13 YWCA of White Plains and Central Westchester, New York, residence cluster. (James D. Lothrop, Architect.)

Residences

One of the earliest services the YWCA undertook for the benefit of women and girls was that of providing housing within the budget of employed girls and offering a protected living situation. For many years that service was considered essential and sufficiently in the interest of the community and the individuals to warrant a sizable subsidy. Increasingly, as the need for the protective aspect has decreased and as other housing for employed women has become available, subsidy of YWCA residences has been withdrawn.

Because the YWCA has an obligation to maintain high standards of residence operation, a residence should not be continued nor included in a new building unless the long-term demand will be sufficient to provide enough residence income to carry the full cost of operating the unit according to these standards.

A decision to include a residence in a new YWCA building should be based on a careful study of the need for it in the years ahead as well as on current demand for that type of housing. The changes in the demand for YWCA residence facilities and the requirement that the operation pay its own way, with all legitimate costs charged to it, make the decision a serious one.

If a residence is contemplated in a new facility, it can be considered either in relation to and as a part of an activities building or as a separate unit. If it is part of an activities building, there will be certain economies in operation that will decrease operating cost. On the other hand, if demand for those facilities does not hold up, it is not easy to adapt the space to other uses; and, if that were possible, there is no assurance of a need for that much additional activities space. A separate unit may be more costly to construct and will be more expensive to operate. Services like those of the front desk must be duplicated and additional lounge and other space must be provided. The advantage of a separate unit located so that sale of it will not unduly affect the use of the activities building is that it gives a certain amount of flexibil-

ity. It must be remembered, however, that a building designed for a specific use is less salable than one that can be converted to other uses.

In an entirely separate housing unit, a large bed capacity will be required to support such things as lounge, front-desk utilities, and night service to admit late arrivals. Office space need not be provided for the business and administrative aspects if these are carried at the branch or metropolitan level. However, there should be an office for individual interviews of applicants for rooms and for counseling. Lounge space should be provided on the first floor for residents to entertain their guests and should permit supervision from the main desk. In addition, there might be a small lounge on each floor or so for the exclusive use of the residents.

If food service is provided, it should be located on the main floor so that residents can entertain guests without taking them into the living area. It takes a large residence to support food service unless it is also open to participants in the program in the activities building and/or to the public. It might be feasible to have kitchenettes with refrigerator, locker space for limited storage of food, and dining space for the permanent residents.

Most of the rooms for residents should be single. A limited number may have twin beds, but the trend is definitely toward singles for both permanent and transient use. There should be a lavatory in each of the rooms if there is no private bath. Preferably, bathrooms should provide a shower or tub and a toilet for every five to six occupants. Transient space should be separated from that for permanent residents so far as possible.

The floor space needed in permanent rooms will depend somewhat on the amount of storage space and the amount and location of built-in units. A small room can be more comfortable to live in and more easily cleaned if there is sufficient closet space. A storage room for large suitcases and boxes should be readily available so that it is possible to require that they not be kept in sleeping rooms.

In addition to a limited amount of drying

space in each room, laundry facilities should be provided for the use of permanent residents.

Built-in furniture may represent a real economy, but some furniture should be movable so that room arrangements can be changed. Electric outlets should be placed so that regrouping of furniture, including lamps, will not present the hazard of long extension cords on the floor. Provision of a bulletin-type board or some other device for hanging pictures or ornaments will save walls. Furnishings should be such that curtains and floor coverings can be changed for different color combinations.

The residence director needs a suite with bedroom, bath, living room, and a small kitchenette located where she can be aware of activity yet have privacy when off duty. Unless the residence is large enough to have a night matron on duty, the director's rooms and also one other room for a relief person should have a buzzer connected to the front door so that guests arriving after closing hours can be admitted.

There is a recent experimental trend toward providing apartments within the YWCA residence. In communities where there are industries employing large numbers of young, single women and where there is a shortage of apartments for rent, the YWCA can provide an answer to the need for private living accommodations if this can be made economically feasible.

Another experimental type of residence facility, along the lines of the Evangeline Residences in England, consists of clusters of rooms grouped around a common kitchen, dining, and living room. These clusters vary from seven to nine rooms generally and provide a small group setting.

In addition to and in conjunction with the traditional purpose of the YWCA residence, many associations provide transitional housing for girls and women with special problems. The YWCAs have used their facilities in working relationships with the Job Corps, mental hospitals, probation agencies, schools, and other agencies for housing women who need supportive, counseling, and educational facilities.

By HOWARD M. WILLIAMS, Director, National Building Consultation and Supply Services, Boys' Clubs of America

A boys' club building is what the name implies—a building designed primarily for use by boys. For that reason alone, it is unique. It should contain adequate facilities for a well-balanced program of recreational, physical, social, and educational activities. The size of the facilities should be in proportion to the number of boys to be served, and facilities should be provided to serve approximately one-fourth of the active membership of a boys' club at any time. Where permitted, single-story buildings are highly desirable because they are easier to supervise than multistory structures. Avoid construction of buildings with more than two stories because of increasing cost of fire-proof or fire-resistant building materials. Roof playgrounds also are not recommended because they are expensive to construct and difficult to keep free from leaks.

Types of Space

A boys' club building contains two general types of space—program and service. The program space is divided into recreational, social, educational, and physical areas. (1) Recreational space includes a games room for "midgets," juniors, and intermediates and a lounge for older boys. (2) Social program space consists of clubrooms and lounges. (3) Educational program space contains rooms for shops, classes, and library. (4) Physical program space consists of a gymnasium, natatorium, special exercise room, and dressing and shower rooms. (5) Service space includes offices, toilet rooms, stairs, corridors, storage rooms, and boiler rooms. Usually the percentage of boy capacity of a building is distributed as follows:

Physical education facilities	40 percent
Recreational facilities	25 percent
Educational facilities	25 percent
Social facilities	10 percent

A kitchen is also essential. In many clubs, kitchens are used for social events and cooking classes, and by boards of directors, women's auxiliaries, mothers' clubs, parents' clubs, and service organizations.

It is desirable to provide some space for health services, such as physical and dental examinations, but a room designed expressly for this purpose is not essential. If a club has a visitors' or girls' dressing room, it can be easily adapted. (See Figs. 1 to 3.)

With the exception of the games room and the dressing rooms, boys should not be required to pass through one activity space to reach another. If all facilities cannot be placed on one floor, it is desirable to locate activity spaces accommodating large numbers of boys, such as games rooms, gymnasiums, swimming pool, and locker rooms, on the first floor within easy access of the lobby.

Locate offices and control desks or counters at strategic points along lanes of travel where one staff member can overlook or give visual supervision to two or more areas. Offices and toilet rooms should be adjacent to the lobby,

games room, or corridors, thereby accessible without passing through an activity area.

Provide as much storage space as possible within the limitations of the structure. It is a well-known fact that most boys' clubs do not have adequate space for storage of equipment and operating supplies. A roomy closet on each floor for maintenance supplies is also essential. This closet should contain a slop sink and shelves and should be large enough for mops, brooms, a polishing machine, vacuum cleaner, and other cleaning supplies. This room should be well ventilated.

There is no basis for determining the minimum amount of storage space which should be provided, but again, few boys' clubs ever have enough. Some authorities estimate that at least 4 percent of the total floor area should be allocated to storage. Too often, when limited funds require a plan to be reduced in size, the storerooms are first in the process of elimination. When sufficient storage space has not been provided, it generally becomes necessary to use some activity space for this purpose, thus reducing the amount of service which can be rendered to boys.

Minimum office space in a building includes room for the following: general office or control desk, executive office, and an office for the physical director. An office for other staff members is desirable but not essential.

Other Facilities Which May Be Added:

Regulation gymnasium (60 by 80 ft)	Additional offices for staff members
Swimming pool	Enlarged or additional crafts rooms
Additional rooms, which might include a room for older boys	More storage space
Health examination room	Group club rooms and an auditorium, depending upon requirements of the community
Larger kitchen	

When planning a small boys' club building, it is important to bear in mind the possibility of future expansion. It is especially desirable to

consider the addition of a swimming pool, no matter how remote the idea may appear at the time. A minimum boys' club building should contain facilities for 100 boys (in simultaneous occupancy). Minimum facilities should include the items indicated in Table 1.

TABLE 1 Minimum Facilities for Building

Room	Approx. minimum dimensions, ft	Boy capacity
Games room	28 by 42	42
Gymnasium	30 by 60	
(not necessarily regulation size)	20-ft ceiling	30
Dressing room	15 by 24	(30)
Library-group meetings	17 by 17	14
Crafts room	17 by 18	14
Toilet rooms		
Storage rooms		
Offices		
Kitchen		
Total boy capacity		100

RECREATIONAL ACTIVITY SPACE

Games Room

The games room is one place in a boys' club where any boy may participate. The high cost of construction and supervision has made it necessary to reduce the number of games rooms to one or two. It is desirable to have separate rooms for the younger and older boys. Most clubs prefer a midget-junior room and a senior lounge.

Twenty-five to thirty percent of the boy capacity of a building should be devoted to recreational or games room activities. The basis for determining the size of a games room is as follows:

Cadets or "midgets"	20 sq ft per boy
Juniors	25 sq ft per boy
Intermediates	25 sq ft per boy
Seniors	30 sq ft per boy

Fig. 1 Boys' Club (building 136).

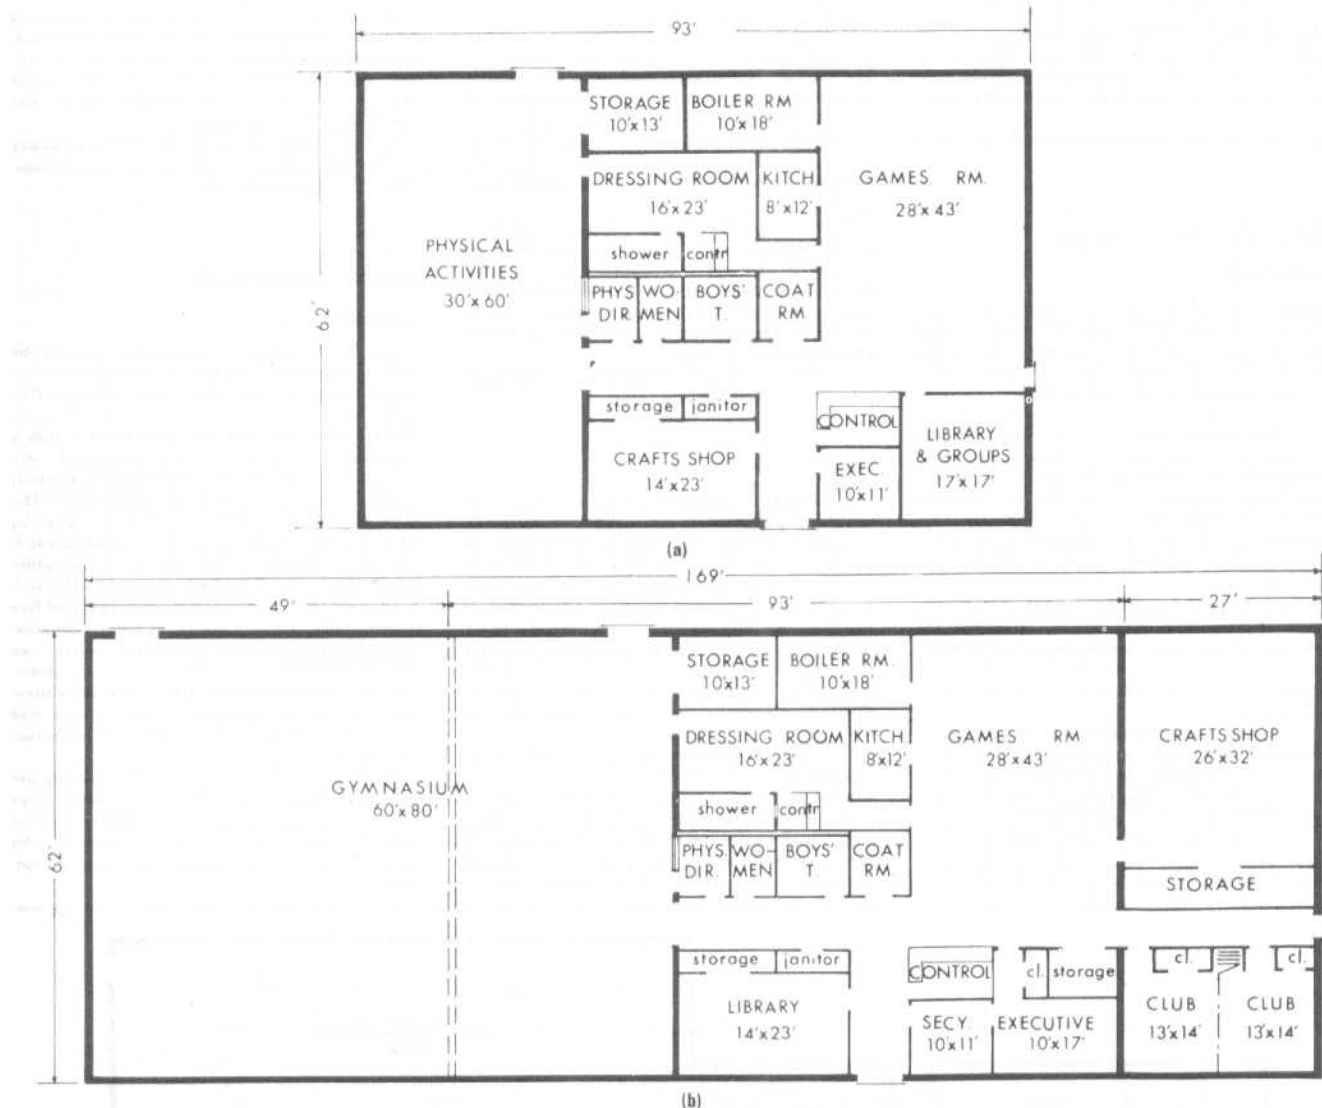

Fig. 2 Boys' Club building 100-200. (a) Unit one, regular program capacity: 100 boys simultaneously. (b) Unit two, regular program capacity: 200 boys simultaneously.

Where it is necessary to provide for more than one age group in a games room, the largest square foot factor should be used.

Locate the general games room near the club entrance. It is desirable to locate the senior lounge where it can receive some supervision from the general games room attendant.

Provide a variety of games for individual and group participation in the general games room. The room and equipment should be flexible enough to permit games tables to be rearranged or changed to meet the needs of the membership. Games tables should be sturdy and *not* fastened to the floor. Most tables are 30 in. high; some should be lower for use by younger members.

Where space and funds for building are limited, it is often necessary to combine programs in one room. It has been established that certain craft activities can be carried on in a games room. These should be of a quiet nature, such as soap carving, plastic pins, gimp work, leathercraft, shell craft and bead or cork work. (Activities such as woodworking are obviously not practical.) These programs may be operated simultaneously rather than

closing down the games activities, but combined activities should be considered only as a last resort.

There should be a counter for storage and display of game equipment that can be checked.

The older boys' or senior room should be a combination lounge and games room. Equipment should include games tables, easy chairs and sofas, a piano, hi-fi or television, and a writing desk. However, where space for building is limited, the basic facilities of a boys' club must be included first.

Games room ceilings should be at least 12 ft high to minimize damage from pool cues. Acoustical treatment is highly recommended.

SOCIAL ACTIVITY SPACE

Club Rooms

Every boys' club should have at least one room for group meetings, and larger clubs usually need about three group club rooms. For maxi-

mum use of these rooms, they should be located adjacent to each other and separated by sound-resistant, flush-folding partitions. These folding partitions permit flexible combinations of small rooms, one small and one large room, or just one very large room to accommodate any type of meeting, luncheon, or dinner.

A kitchen should be located adjacent to the club room or within proximity for snacks, meals, and luncheon or dinner meetings. Ample storage rooms are essential to accommodate equipment.

Fifteen square feet per boy is the basis for determining the size of a club room, minimum capacity for this room being not less than 10 boys.

Kitchen

A kitchen is one of the minimum essentials for a boys' club building. This room should be large enough to accommodate cooking classes. The kitchen may also be used in combination with a canteen. (See Fig. 4.)

Kitchens should have ranges, refrigerators,

BOYS' CLUBS

sinks, and cabinets of sizes and capacities proportionate to the room area and to the extent to which they will be used. The average club kitchen seldom prepares and serves food to groups exceeding 100. Service for larger gatherings (banquets, etc.) is generally delegated to local caterers who are better equipped.

EDUCATIONAL ACTIVITY SPACE

Crafts Shops

Larger boys' club buildings usually have several rooms devoted to arts and crafts. These may include space for fine arts, ceramics, woodworking, photography, and small crafts.

The importance or popularity of arts and crafts in a boys' club depends on the leadership available and the geographical location of the community. Usually every club has one room set up for woodworking because it is popular with boys all year long. If this room has a variety of tools and enough electrical 110- and 220-volt outlets, it is possible to vary the arts and crafts classes to conform with members' desires.

A crafts room to accommodate at least 20 boys is desirable. Leadership available for various crafts will determine the size of classes, but the minimum should be space for 20 boys. In a small club, a room for 14 boys is acceptable.

Forty-five square feet per boy is the basis for determining the size of a woodworking shop. This includes space for workbenches, some storage cabinets, power tools, and aisles. Forty square feet per boy is acceptable for a woodworking shop without machine tools. The size of a room for small arts and crafts is determined on the basis of 35 sq ft per boy.

Since many crafts use the same tools, it is

possible and desirable to carry on more than one craft at the same time in the same room, provided there is ample storage space and leadership. There is a definite trend toward having one large room to accommodate all arts and crafts. Such rooms are equipped for lapidary or ceramics, woodworking, and electronics. Larger clubs usually have a separate room for art work. Some may have two or more shops.

Every arts and crafts room should have ample storage space for tools, materials, and unfinished projects. A separate finishing room for painting handicrafts is desirable. This room should be well ventilated with access to the outside so that fumes from painting and paint staining will not remain.

Provide a sink with both hot and cold water in every arts and crafts room.

Library

The library is usually located along a route which large numbers of boys use to travel through the building. The room should be attractively furnished so boys will want to go in to read or do homework. The library should be able to accommodate about 10 percent of the daily boy attendance. The acceptable basis for determining the size of a library is to allow for not less than 20 nor more than 25 sq ft per boy. This is sufficient to include space for furniture, bookshelves, and a desk for the librarian.

If space is available, two or three study cubicles are very desirable.

Adjustable bookshelves, not exceeding 5 ft in height, should be located along one wall. Additional shelves may be added as required. Informal furniture is suggested and should include round tables, straight-back chairs, low stools, easy chairs, librarian's desk, and a

magazine rack. All furniture should be sturdy enough to withstand the rigors of use by youth. Some small chairs and tables for the seven- and eight-year-olds are recommended, since this group cannot sit comfortably in regular chairs at regular table height.

A small reading room should have a variety of furniture suitable for space limitations. Provide at least one table.

PHYSICAL ACTIVITY SPACE

Gymnasium

A boys' club building, especially if it is to be used by older boys, should have a gymnasium large enough to provide at least a regulation junior high school basketball court. The gymnasium, however, should be more than just a basketball court. Floors and overhead construction should be strong enough to support various types of gymnastic equipment. The most desirable size for a gymnasium is 60 by 80 ft overall inside dimensions. Such a room will accommodate a 42- by 74-ft regulation junior high school basketball court with minimum 3-ft sidelines around three sides, and five rows of folding bleachers along the fourth side. Two 40- by 60-ft cross or practice courts can also be included in this area. These are desirable not only for basketball but also for volleyball, etc. Senior high school and college size courts are acceptable when funds for construction and space are available.

As noted, small buildings with inadequate gymnasiums are undesirable when older boys are to be served. However, in minimum-sized buildings or when extension or branch clubs are planned, smaller gymnasiums are acceptable.

Space for spectators is needed in any gymna-

Fig. 3 Boys' Club building. (a) 215-320. (b) 288-393.

sium regardless of size. This space should be on the gymnasium floor where it can be easily supervised. Second-story balconies for spectators are costly to construct, difficult to supervise, and usually do not permit full vision of all parts of the gymnasium floor. Folding bleachers are best for use in spectator space, but movable bleachers are acceptable. There should be no permanent bleachers or chairs on the gymnasium floor because they present a hazard to participants in the physical program and reduce the width of the room for cross-court purposes. Generally, the maximum number of spectator seats is 150. In some communities, much more spectator space might be wanted.

Clear height from floor to bottom of trusses must be 20 ft for a 60- by 80-ft gymnasium. Amateur Athletic Union rules and some building codes require more than 20 ft of clear height.

Many boys' club gymnasiums are used at times as auditoriums. Very often a stage is provided at one end. However, because some building codes place so many conditions and restrictions on built-in stages, it is not always economical to provide one. In such cases, portable stages or platforms may be used.

A good-sized storage room for gym equipment is essential. Doors to these rooms should be 6 ft wide and 7 ft high to accommodate flat mat trucks and a trampoline.

An office for the physical director is necessary. This should be located on the same level with the gym floor and preferably in a spot where people will not have to cross the gym floor to reach it.

Simultaneous use by 40 boys is considered maximum capacity for a gymnasium, as it is difficult for one instructor to handle any more at one time.

Swimming Pool

An indoor swimming pool is a tremendous attraction to the boys' club. Swimming is one of the most beneficial activities in maintaining physical fitness and health. A swimming pool encourages cleanliness and personal hygiene, since each boy must take a shower with warm water and soap just before entering a pool. Swimming is a group activity that helps build self-confidence and gives each boy a chance to play with his friends and develop socially. In surveys of popular boys' activities, swimming is at the top of the list.

The 30- by 75- and 35- by 75-ft pools have been recommended as desirable sizes for boys' clubs by the Boys' Clubs of America National Committee on Aquatics. The Amateur Athletic Union's requirement for the length of a pool is 75 ft 1 in. in order to take care of any irregularities in construction. A boys' club swimming pool should never be less than 60 ft in length. Since there is very little difference in cost between a 60- or 75-ft pool, the shorter pool should be considered only when site limitations prohibit a 75-ft pool. The minimum size is 25 by 60 ft. Other sizes are 30 by 60 ft, 25 by 75 ft, 30 by 75 ft, 35 by 75 ft, 42 by 75 ft, and T-shaped pools with a tank of either 30 by 75 ft or 35 by 75 ft.

Seventy-five-foot pools are acceptable for competitive swimming. The recommended width of swimming lanes is 6 ft for pools up to 30 ft in width, and 7 ft for pools 35 ft and over in width.

Space for spectators should be provided in the swimming pool room. Most state public health regulations require spectator space to be separated from the pool deck to prevent people in street shoes from walking on the deck. It is desirable to have the spectators' gallery near the pool deck level, not at second-

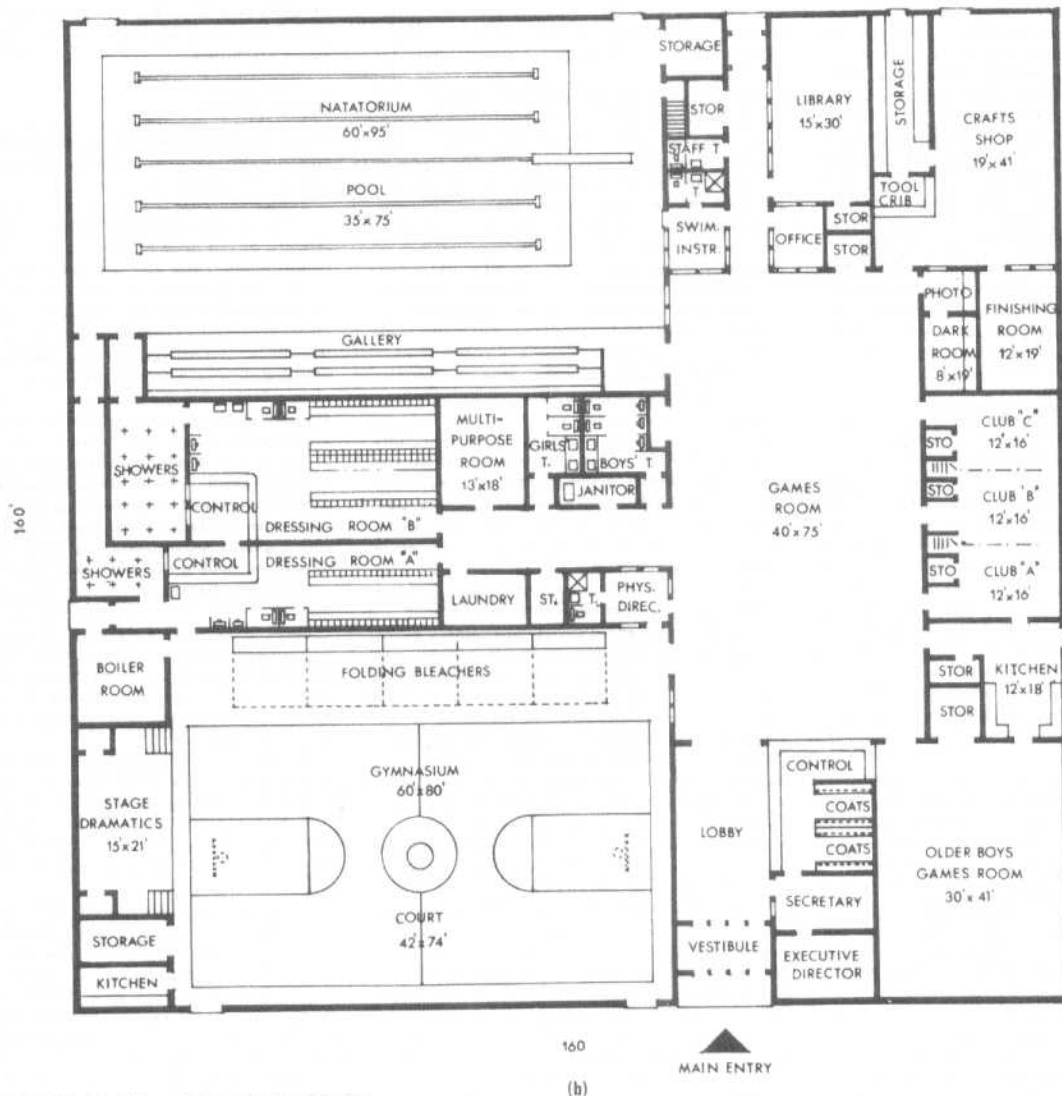

Fig. 3 (cont.) Boys' Club building. (a) 215-320. (b) 288-393.

BOYS' CLUBS

story height. The gallery is needed for parents and visitors and also for class instruction.

Overall minimum ceiling heights in natatoriums are sometimes determined by local ordinances. In any case, the minimum clear height in the diving area should be not less than 15 ft above the diving board. This clear height should be maintained for a minimum distance of 10 ft in front and 5 ft to the rear of the front or tip, and at least 10 ft on each side of the diving board.

Boys' club swimming pools should have 1-meter diving boards only. Three-meter boards and diving towers are not recommended because they are very difficult to supervise.

Depth of the swimming pool at the deep end should be not less than 8 ft 6 in. in front of a 1-meter diving board. Depth at the shallow end should start at 3 ft and slope to 3 ft 6 in. in a distance of 22½ ft for a pool 60 ft long and 35 ft for a 75-ft pool. Although local regulations may dictate otherwise, the foregoing is recommended for boys' club pools because more shallow-water area is desired for teaching purposes. If local or state codes require the pool floor to be pitched more, a variance should be obtained.

Minimum recommended width for decks around any pool is 5 ft. A 10-ft-wide deck on one side (preferably the side with the spectators' gallery) is useful for instruction purposes. The recommended width of the deck at the diving end of the pool is 13 ft 6 in.

Windows in the natatorium should be carefully planned. If they face south and/or west, the windows should be close to the ceiling. Large windows, especially those facing south and west, permit too much sunlight to enter the room. Excessive natural light places too much glare on the pool surface, thus making it difficult for the swimming instructor or lifeguard to see the bathers. Too much sunlight also encourages the growth of algae, which will make the water cloudy. Many colleges, universities and boys' clubs are now building natatoriums with no exterior windows of any kind. Since artificial illumination is used whenever the pool is in operation, windows are not needed. (See Fig. 5.)

Underwater lights are desirable not only for their esthetic value but also for safety, as they make it possible for the instructor to see all boys in the pool. These lights should be cast into the concrete walls and staggered along the sides of a pool for even distribution of light. They should never be located directly opposite each other. Do not place underwater lights in the ends of a pool.

Most state public health regulations require public and semipublic swimming pools to use the "recirculation" water purification system. This means water is continually drawn from the pool and replaced by freshly processed water. The drawn-off water is screened, filtered, chemically treated, and heated until restored to its original purity.

Recirculation pools can be divided into two categories: The conventional scum gutter and the water level or flush deck. The physical difference between the two is that the former has a scum gutter set into the walls of the pool, while the water level deck has moved the gutter from the side walls to the deck. Water level in the scum gutter pools varies from several inches to as much as 2 ft below the decks; water in the flush deck pool is always within ½ in. of deck level.

The primary operational difference is that many state public health ordinances require water entering scum gutter drains to flow directly to the sewer. Any water drawn off through the scum gutter is thus irretrievably

Fig. 4 Three-club-kitchen combination. Serving 20 boys per hour in each club room.

lost, as is the heat it contains. Water overflowing into the drains of the water level deck pool is carried to a balancing tank or reservoir where it is held until it is chemically treated and the pump can recirculate it through the filters back to the pool. No large quantities of water or heat are lost in this process.

The idea of water level deck swimming pools originated in Boys' Clubs of America in the late 1930s. Since that time most new boys' club pools have used the design, as have recreation departments, schools, the U.S. Navy, the Royal Canadian Air Force, and various youth organizations. Water level deck pools are ideal for teaching swimming. The instructor does not have to stand at the very edge of the pool to see everyone in the water, and nonswimmers feel safer because they can see the whole room and the instructor. This is not true of some of the old scum gutter pools where the bather can see only the ceiling and the sides of the pool. Nonswimmers and beginners also feel safer in a flush deck pool because they can get out of it at any point around the pool's perimeter merely by placing hands on the deck and kicking the feet. Ladders are not necessary, although some local ordinances require their installation. Actually, ladders are more of a liability than an asset in water level deck pools, but if they are required by law, make sure that they are the removable type.

Water level deck pools must be carefully designed so that all water washed over the decks will drain quickly into the overflow trenches. Overflow water must never be permitted to wash back into the pool. Also, to be efficient, the reservoir or balancing tank must have sufficient capacity to store the overflow water until it is recirculated through the filter system and pumped back into the pool.

Chlorine is the most widely acceptable agent for purifying pool water. Bromide, iodine, and other chemicals are also used, but these have not been approved by all public health authorities. There are two types of chlorine—liquid and gas. Gas chlorine is less expensive than liquid, but it is extremely poisonous and is dangerous if handled incorrectly or if a leak should develop in the tank in which it is stored. Several times during any given year, articles appear in newspapers about the many people who are critically or fatally injured because of a chlorine leak or because a tank of chlorine gas fell off a truck and exploded. Some cities now prohibit use of gas chlorine in swimming pools. Liquid chlorine is a bit more expensive but much less dangerous. It will bleach dyes and eat holes in woolen material, and it is poisonous if taken internally in its concentrated form. But liquid chlorine will not contaminate the atmosphere. Chlorine can be purchased as a liquid or in powder or tablet form to be dissolved in water. It should be fed into the water

recirculation system by means of a mechanical chemical feeder to ensure proper dosage and mixing.

Filters most commonly used for boys' club swimming pools are the pressure sand and gravel filters and the vacuum diatomaceous earth filter. In recent years, high flow pressure sand filters have been developed. These are smaller and less costly than the sand and gravel filters. No matter which type is chosen, filters and the pumps used with them should be of sufficient capacity to recirculate the pool water at least every eight, or more preferably, every six hours.

Dressing Rooms

Dressing rooms should be located adjacent to and on the same level with the gymnasium and/or swimming pool.

Before the size of a dressing room is determined, consideration should be given to the climate of the area in which the boys' club is to be located, the age groups and number of boys to be served, and the activities requiring dressing room use. As a general rule, for the younger or midget group, small lockers approximately 12- by 12- by 12-in. in size are recommended. In most cases, the small lockers are also suitable for the junior group. The 12- by 12- by 30-in. double-tier locker is recommended for intermediates and seniors. Regardless of the size of lockers, there should be enough to accommodate the maximum capacity of the gymnasium and/or swimming pool plus an equal number to provide for change in groups—this means a gymnasium with 40-boy capacity should have 80 lockers (see Fig. 6).

Minimum distance between rows of lockers should be 8 ft 6 in., measured from back to back of lockers. This allows a minimum of 12 in. on each side for lockers, 16 in. for a bench attached to the base of each row of lockers, and 3 ft 10 in. for aisle space. Benches are essential in dressing rooms, regardless of the type of lockers used.

Basket and bag systems are acceptable under certain conditions. They are less expensive than lockers and occupy less space. The principal objection to these systems is the difficulty in managing them. An attendant has to handle each basket or bag four times to service one boy.

It is essential to provide toilet facilities close to the shower room entrance. If such facilities are not immediately available, the shower room floor will be used as a substitute. When a dressing room is used to service a swimming pool, toilet facilities are usually required by law. Small dressing rooms should have at least one water closet, urinal, and lavatory; large dressing rooms should have two of each. The use of dressing room toilet facilities for the

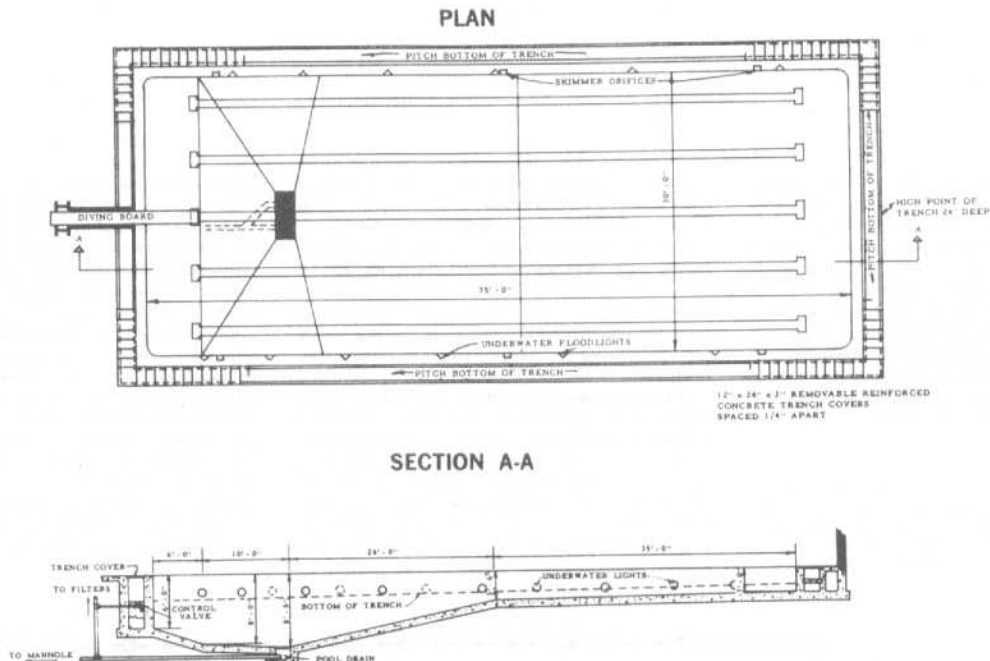

Fig. 5 Natatorium.

entire boys' club is not recommended, since such combined use increases problems in supervision and results in water being tracked into the club.

Plan locker rooms so the attendant in the control cage can see the entire room and also the shower room.

Shower Room

The number of shower heads recommended for a dressing room serving a gymnasium is five. The number of shower heads recommended for a swimming pool dressing room is twelve.

Shower heads should be suspended from the ceiling with the bottom of the head not less than 8 ft nor more than 9 ft above the floor. Ceiling shower heads, rigid and without ball joints, are recommended because four boys can shower under one head. Wall shower heads can accommodate a maximum of two boys.

Any wall projections in shower rooms are a source of injury to boys.

SERVICE SPACE

Executive's and Secretary's Offices

Locate the secretary's office directly adjacent to the club entrance so the person working there can see who enters or leaves during the morning and afternoon when the building is not completely staffed.

The executive's office should be next to the secretary's office and also close to the club entrance, where it is easily accessible to boys, parents, and visitors.

In communities where the boys' club has one or more branches or where the club must have a more complex office arrangement, the unit director's office should be adjacent to the entrance. The secretary's and executive's offices and a workroom may be located in a different section of the building.

Windows are recommended for interior walls so the executive can see what is going on outside. Provide venetian blinds or draw curtains

over these windows to ensure complete privacy during consultations and interviews.

Control Counters

As previously stated, control counters should be located where the attendant can see the area to be served as well as other areas.

Height of control counters should be no more than 40 in. A low section of 33 in. for young boys to fill out membership applications is recommended.

Games control counters should have cabinets below them for storage of supplies.

Toilet Rooms

Locate boys' toilet rooms adjacent to the lobby or corridor where they are easily accessible. It is desirable to have toilet entrances near a con-

trol desk from which an attendant can see those who enter or leave the room.

Local codes in many cities and states govern the minimum number of water closets, urinals and lavatories which must be installed in public buildings. These are usually determined by the maximum capacity of a building. In communities having no codes or ordinances requiring adequate toilet facilities, the following formula is recommended:

- 1 water closet (toilet) for each 50 boys
- 1 urinal for each 50 boys
- 1 lavatory for each 100 boys

Wall-hung water closets, lavatories, and urinals are preferred. Some wall-hung urinals should be set lower than standard heights to accommodate small boys. Stall urinals are acceptable. With fixtures on the walls, floors are easier to clean.

Fig. 6 Locker diagram. 60- and 30-in. double-tier lockers.

Recreation buildings should provide a safe, healthful, and attractive atmosphere in which every person in the community or neighborhood has the opportunity to enjoy his leisure by participation in activities of a social, creative, cultural, or physical nature.

Planning Areas and Facilities for Health, Physical Education, and Recreation, rev. 1966. The Athletic Institute, Merchandise Mart, Chicago, Ill.; American Association for Health, Physical Education, and Recreation, Washington, D.C.

Almost without exception, recreation areas require some type of structure which will fulfill program needs and yet blend aesthetically into its surroundings. In terms of function, building types may range from the simple picnic shelter to the complex community recreation building with its variety of special service facilities. Such buildings may vary in design from the rustic, depicting the style of early colonial

In many neighborhoods and communities, school facilities are adequately equipped to provide recreation programs for youth, but other existing age groups are not always served. In such instances, the community must depend upon public recreation facilities which are planned and operated independently to accommodate a recreation program for the total community. Since the school is an integral part of the community, it should have a part in the planning of public recreation facilities. Conversely, when school buildings are being designed, cooperative planning with community recreation authorities is essential in order to assure that the new structures will include facilities needed for joint school and community use.

Fig. 1 Collett Street Recreation Center, Morganton, N.C.

PLANNING OBJECTIVES

The planning and designing of a recreation building demand a precise and logical approach. Since a recreation building reflects the unique needs of a neighborhood or community, the specific plans and design will vary, but the preliminary considerations and planning objectives will be the same.

The successful incorporation of accepted planning objectives will ensure maximum utilization of the building. The preliminary plans and the continuous reevaluation of the functional design of the building prior to its construction should be considered in terms of the following questions:

- Has the most effective use of the entire area been determined, and does it utilize all of the natural resources?
- Does the preliminary plan include all of the essential areas and facilities necessary to fulfill the program objectives?
- Does the design provide for flexibility in use and for future expansion?
- Does the floor plan permit convenient access to, and facilitate circulation within, the building?
- Does the floor plan provide for ease in supervision and administration of the building?
- Have individual rooms been located and designed so as to encourage multiple use within safety limits?
- Has the building been designed so as to ensure opportunity for its use by all members of the community, including the aging and disabled?
- Does the design encompass accepted aesthetic qualities that relate harmoniously with the surroundings?
- Is the building designed and constructed so as to ensure joint use with other public or private agencies?
- Is the building so designed that it will permit economy in construction and maintenance?

CLASSIFICATION OF RECREATION BUILDINGS

Growth in the scope and complexity of the recreation program has created a need for buildings which will provide facilities adapted for a wide variety of recreation activities. Unlike many of the early structures, present-day buildings provide for adaptability and multiple use. This change from the simple to the complex has stimulated the development of a variety of recreation buildings. These are classified by function and then categorized by size.

The standards used for determining the size requirements of recreation buildings are usually based upon a square-footage-to-population ratio. This may be determined by allowing 1 to 2 sq ft per person to be served. For example, if the building is to serve 8,000 persons, it should be approximately 12,000 sq ft in size. This footage ratio may vary where cities build one center to accommodate the entire population.

Type I Recreation Buildings

The plans in Fig. 1. illustrate a Type I recreation building. This type of building is usually constructed in larger subdivisions or suburban areas of a metropolis. However, recent trends reveal that many smaller cities (30,000 or less) have constructed such facilities to serve the total community.

This type of building encloses 20,000 sq ft or more and usually includes the following facilities:

Multipurpose	Game room
Gymnasium	Photography room
Shower and locker rooms	Office (administration)
Club rooms	Office (staff)
Arts and crafts room	Rest rooms
Lounge and lobby	Kitchen
	Large storage areas

Type II Recreation Buildings

The Type II recreation building is illustrated in Fig. 2. This is the most common type and can be used in any city or community. It is believed by many recreation experts that the most efficiently operated building is the one designed to accommodate a neighborhood or area of approximately 8,000 persons.

This building encloses 10,000 to 20,000 sq ft and includes basically the same facilities as the Type I structure. Room sizes may vary and emphasis may be placed on those facilities that will best serve the program objectives.

Type III Recreation Buildings

These buildings are used in many communities to satisfy the needs of less populated areas and usually include most of the following facilities (Fig. 3):

Social hall or gymnasium
Shower-dressing room
Club room
Lobby-lounge
Office
Rest rooms
Kitchenette
Adequate storage areas

Social Hall-Gymnasium

In order to obtain maximum benefit from the social hall-gymnasium, this facility is ordinarily used for a variety of social activities, such as folk, square, and social dancing, banquets, and roller skating, in addition to basketball and other forms of athletics.

The size of a community recreation building's social hall-gymnasium should be at least 90 by 100 ft, with a minimum height of 22 ft. This will permit a basketball court of 50 by 84 ft.

Fig. 1 (cont.) Collett Street Recreation Center, Morganton, N.C.

Governmental and Public RECREATION CENTERS

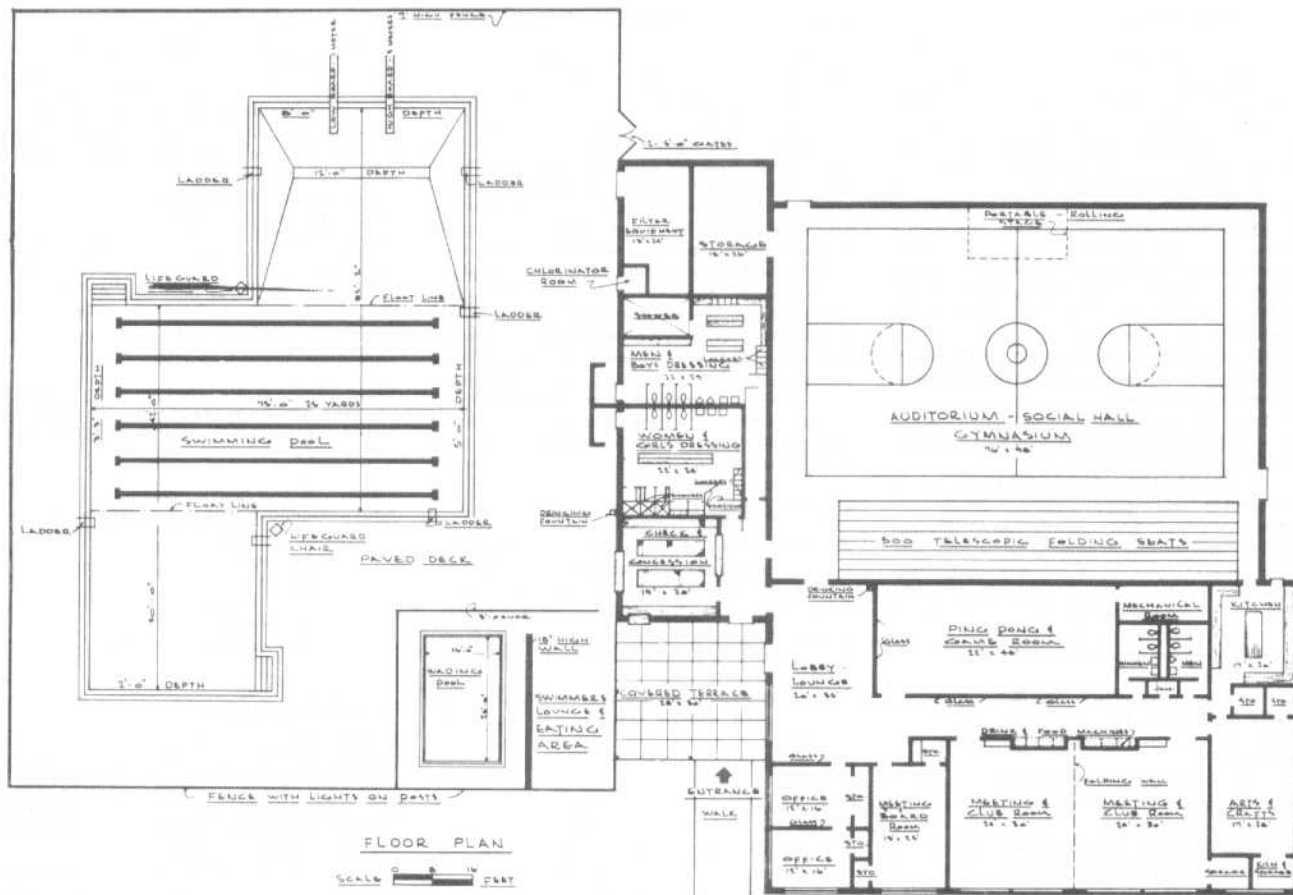

Fig. 2 Thomaston-Upson County Recreation Center, Thomaston, Ga.

These dimensions will permit seven tiers of telescopic bleachers on one side of the social hall-gymnasium, seating approximately 325 spectators.

Provision should be made for a mechanical ventilating system (forced air). The wainscoting should provide clear, unobstructed wall space from the floor to a height of 12 ft. If the room contains windows, they should be placed above the wainscoting on the sides and should be provided with protective guards. There should be no windows at either end of the social hall-gymnasium.

It is preferable to have no windows in a social hall-gymnasium as they have little functional value. If it is necessary to use windows, they should be placed on the north side, or if used on two sides, then on the north and south, never on the east or west. Where sky domes are installed, they should be waterproof, and the room should be equipped with vent domes and exhaust fans for ventilation.

Maple flooring is commonly used. The cork spring clip or other type expansion joint should be installed on all four sides. If suspended apparatus is used in the social hall-gymnasium and wall attachments for control ropes and chains are affixed to the wall, these attachments should be at least 7 ft above the floor level and should be recessed.

This room should be equipped with stainless steel or aluminum portable and removable handrails attached to all wall surfaces, and also along the face of folding bleachers to provide a handhold for roller skaters.

Whenever possible, noncontact (nonmarring) furniture should be used. Design characteris-

tics of such furniture also facilitate safer use by the aging and disabled.

In a masonry building, particularly in one with concrete reinforced frame, stainless-steel eyebolts should be installed in each corner and at each column for the hanging of decorations for special parties. These bolts should be located within 12 ft of the ceiling in the smaller rooms, and at least 15 ft high in the social hall-gymnasium. The use of eyebolts will eliminate the necessity of driving nails or screws into the walls.

THE COMMUNITY RECREATION BUILDING

The community recreation building functions beyond the primary purpose of serving a single neighborhood. It is designed to offer a more diversified program in order to meet the complete recreational needs of all people in the community. The community building is normally larger than a neighborhood building and is usually located in a major recreation area such as a community park or playing field.

As stated previously, community recreation buildings vary in function and design, but, generally, they contain most of the facilities described on the following pages.

Multipurpose Room

The multipurpose room should be designed to accommodate such activities as general meetings, social recreation, active table games, dancing, dramatics, orchestra practice, concerts, and banquets.

The area of this room should be approximately 2,000 to 3,000 sq ft. It should be rectangular in shape with a minimum width of 40 ft. The minimum ceiling height should be at least 16 ft.

The floor should have a nonskid surface to prevent many common accidents. The floor should also be level in order to permit multiple use for meetings, dancing, dramatic presentations, etc.

Stage

A stage and related facilities are frequently included in a community center. They may be built in conjunction with the multipurpose room or, preferably, as a separate unit.

The stage proper should be about 20 ft in depth, and the proscenium opening should be at least two-thirds the width of the room. It is desirable that the approach to the stage from the floor of the main room be by inclined ramp with a nonskid surface to facilitate the physically disabled and aging and to accommodate the movement of equipment.

Consideration might be given to the construction of an outdoor stage contiguous to the multipurpose room. Some buildings have been successfully constructed with a revolving stage for outdoor and indoor programs. Portable or recessed stages might also be considered.

It is desirable that the room be equipped with a modern public-address system, permanently installed with matched speakers and with outlets for additional microphones and phonographic equipment. Consideration should be

given to a master control from the office of the building. All stage lighting should be modern and should be controlled from a dimmer-control cabinet equipped with a rheostat. Provisions should also be made for television installation.

Recessed drinking fountains and cuspidors should be provided and should be located in areas where they will cause a minimum amount of interference. Water fountains should be hand or hand-and-foot operated, with up-front spouts and controls. Protective floor covering or drainage at the base of the fountain should be considered to avoid floor damage.

Dressing-Locker Room

A room for the purpose of changing clothes is necessary and should be in close proximity to the social hall-gymnasium. There are two accepted plans for checking personal apparel: (1) The use of locker rooms with metal lockers; and (2) The use of dressing rooms with a check-room for checking clothing in wire baskets or nylon bags.

Locker Room If the lockers are to be used in connection with outdoor sports, they should be located so the players will have access to them without going through the entire building. The suggested requirements for the locker room in a community recreation building are as follows: for men and boys, 200 lockers; for women and girls, 150 lockers. The placement of lockers should take into account the space requirements of the disabled.

The floor of the locker room should pitch to a central drain or drains to facilitate cleaning and washing. The junction of the wall and floor should be coved. In the women's locker room,

dressing booths should be supplied in the ratio of 10 percent of the total number of lockers. Hair driers and nonbreakable liquid-soap dispensers are also recommended.

Dressing Room with Checkroom The use of galvanized-wire baskets or nylon or plastic bags is growing in popularity. This system will accommodate the same number of users in about one-fourth of the space required for metal lockers. However, there is no saving of space required for dressing.

If there is a possibility of a swimming pool being constructed on this site at some future time, dressing rooms should be located and arranged so as to serve both the gymnasium and the pool.

Shower Rooms

The size of shower rooms is dependent upon the extent of the facilities and the number of persons to be served at one time. Adequate ventilation should be a primary consideration.

For men and boys, it is suggested that approximately 12 shower heads be provided, spaced a minimum of 4 ft apart and 6 ft above the floor level. For women and girls, it is recommended that a minimum of 6 group shower heads and 3 individual shower-and-dressing booths be provided. Shower heads should be 4 1/2 ft above the floor level. Nonbreakable liquid-soap dispensers are recommended, and hair driers are suggested for the ladies' locker room.

To accommodate the disabled, two folding "L" seats should be placed in opposite corners of each group shower to facilitate both right-hand and left-hand approaches.

In the construction of the shower-room

floor, drainage gutters 4 in. deep and 8 to 10 in. wide placed around the perimeter of the shower room will provide a sanitary means of drainage. The central portion of the shower floor, raised above the depressed area, should drain toward the shower drains. A carborundum-impregnated ceramic tile, or its equal, will provide a nonslip surface.

The temperature of water feeding into the shower heads should be 120°F, controlled by means of a mixing chamber rather than by individual control. Vandalproof shower heads should be used.

Club Rooms

Experience indicates the desirability of providing a minimum of 500 sq ft of floor space per club room. For community recreation buildings, at least three to five club rooms should be provided for multiple use. At least one large club room should be located adjoining the kitchen.

When windows in club rooms and lounges are placed high in a wall, they are not broken as often as low windows and they also provide more space for furniture, bulletin boards, pegboards, chalkboards, and exhibits. Since broken window glass is a major problem, a nonbreakable type of windowpane is preferable. Windows may be omitted and sky domes and vent domes used. By omitting windows, the need for drapes, venetian blinds, and curtains—all items subject to vandalism—is also eliminated.

A chair rail or wainscoting to prevent the marring of walls should be installed to a height of 3 ft above the floor. Whenever possible, noncontact (nonmarring) furniture should be used.

Fig. 3 Glenwood Community Center, Greensboro, N.C.

Governmental and Public RECREATION CENTERS

Arts and Crafts Room

A separate arts and crafts room is desirable. However, if this is not possible, then at least one club room should be equipped for crafts, with provision for gas, compressed air, and a modern sink with hot and cold water. The sink should have a clay trap.

Ample storage cabinets, closets, or lockers should be included for the safe storage of craft materials, unfinished projects, and exhibit materials. Base and wall plugs should be provided in all club rooms for the operation of electric irons, sewing machines, power tools, movie projectors, etc. If a kiln is used, it should be placed in an adjoining room for reasons of safety and should be equipped with a heavy-duty 220-volt electrical outlet. Bulletin boards and exhibit cases may be used to display completed projects.

Lounge and Lobby

The lobby of the community recreation building is the space just inside the entrance. The lounge should open off the lobby, and, if possible, should be close to the central office and to the multipurpose room and/or social hall-gymnasium. The lounge and lobby are often combined into one room. When they are combined, it is suggested that the size of the lobby-lounge be about 600 to 800 sq ft.

This facility should be attractively lighted and should contain a wall-mounted, recessed drinking fountain and a built-in electrically lighted trophy case and bulletin board. Appropriate space should be allowed for public telephones, and at least one telephone should be installed so as to accommodate a person in a wheelchair. Provision should also be made for aquariums and for growing plants and flowers. Adequate space, preferably recessed, and electrical and water connections for automatic vending machines should be included.

The office, club rooms, game room, and rest rooms are usually adjacent to the lobby-lounge.

The entrance doors of the lobby present a problem from the standpoints of aesthetics, safety, security, and vandalism. Solid glass panels—from ceiling to floor—and solid glass doors are quite popular and attractive, but their use must be carefully studied. Since glass doors and panels can be easily broken, good aluminum doors with a minimum of glass are preferable.

One of the main causes of damage to floors is the habit of many individuals of dropping a cigarette on the floor and stepping on it. This habit causes definite damage to asphalt or vinyl-asbestos tile, disfiguring and discoloring light colors and, to some extent, even marring darker colors. Therefore, terrazzo, quarry tile, and patio tile are preferable.

Game Room

The game room, approximately 30 by 64 ft in size, is designed for a variety of games, including billiards and table tennis. In planning this room, sufficient storage space should be provided for various items of game equipment and supplies to be used.

This room should be in close proximity to office supervision. It should also be acoustically treated, due to the noise factor.

The choice of floor material should be carefully considered because of the heavy traffic usually prevalent in this room. Windows should be placed high in the walls to reduce glass breakage. A chair rail or wainscoting to prevent the marring of walls should be installed to a height of 3 ft above the floor. Whenever possible, noncontact (nonmarring) furniture should be used.

Photography Room

A special room can be provided and equipped as a darkroom. Ventilation should be provided through the use of lightproof ventilators. Hot and cold running water, special light plugs—both wall and base—and photographic sinks for developing and washing prints should also be provided.

A mixer is desirable to accurately control the water temperature. A filter should also be provided if the water quality is not good. Doors should be lightproof.

Director's Office

An office of approximately 120 sq ft in size is suggested, with sufficient window space to provide maximum supervision of the lobby, lounge, club rooms, and social hall-gymnasium. At least three walls should have windows. If there is a window connected to the social hall-gymnasium, a nonbreakable-type glass is preferable.

It is often recommended that there be an adjoining shower-dressing unit with a floor-surface area of not less than 100 sq ft. This unit should contain a shower, toilet and lavatory, clothes closet, and first-aid supply cabinet.

Opening off the director's office should be a storage closet with a burglarproof door for storing valuable supplies and equipment, such as the motion-picture projector and public-address system.

Rest Rooms

Rest-room facilities should be designed to serve both indoor and outdoor areas. Provision should be made for direct access from the exterior of the building at a point adjacent to such activity areas.

Rest rooms should include multipurpose units, combining automatic towel and soap dispensers, mirror and shelf, and a combination paper-towel dispenser and waste receptacle. These units should be recessed in the wall.

Mirrors should have metal frames and be recessed into the wall so they cannot be torn off. The preferred soap dispenser is built into the lavatory since this type is less subject to vandalism than the wall-installed type.

Dressing-room benches should be of a permanent type and should be securely anchored to the floor so they cannot be turned over, stacked against the wall, broken, or removed from the building. Toilet fixtures should be hung from the wall for ease in cleaning. In rest rooms where several fixtures are used, one fixture of proper height for young children and the disabled should be included. Lavatories should be of enamel-coated iron or other unbreakable material rather than vitreous china.

A flush-valve water closet with the valve 24 in. above the top of the fixture—or 3 ft above the floor—is preferred over a tank-type toilet fixture. Automatic valves for water taps in showers and lavatories are recommended to reduce water loss caused by taps being left open. Hose bibbs should be installed in each rest room and/or shower room, at a proper height so buckets can be placed under them.

Toilet facilities should be made accessible to the disabled.

Kitchen

The Pullman or kitchenette-type kitchen is usually desirable for most community and neighborhood recreation buildings. If large dinners or banquets are to be served, provision should be made for a full-size modern kitchen that con-

forms to local health regulations and has a free floor space at least 54 in. wide.

The kitchen should be located near the club rooms and the social hall-gymnasium. This will make the kitchen available to small gatherings in the club rooms and to large banquet gatherings in the social hall-gymnasium. The kitchen is often placed between two club rooms and made available to both rooms by the use of aluminum roll-up doors.

Adequate storage space, cabinet space, and electrical outlets for such appliances as the refrigerator, the range, the dishwasher, and can openers should be provided. Exhaust fans should also be installed.

Storage Areas

One of the most common errors found in many recreation buildings is the lack of sufficient storage space for equipment, maintenance, and custodial purposes.

Equipment Storage Room Provision should be made for storing apparatus and equipment. There should be an opening 6 ft wide with louvered flush doors between the social hall-gymnasium and the storage room. This will permit passage of the most bulky equipment. There should be no raised threshold.

The minimum size of the storage room should be approximately 250 sq ft. Provision should be made for storage of inflated balls, bats, softballs, and other supplies, either in separate cabinets or a special closet. Appropriate bins, shelves, and racks are suggested. In addition, a recessed alcove for the storage of a piano is desirable.

Maintenance Storage Room The maintenance storage room varies in size, depending upon the adjacent outdoor space and the size of the building. The room is ordinarily located on the ground level, adjacent to the outdoor areas. An outside entrance should be provided by means of a burglarproof door sufficiently large to permit the passage of motorized and other maintenance equipment.

This facility is used as a headquarters for all outdoor maintenance. It may have to house rakes, shovels, hose, marking equipment and supplies, hand tools, power tools, and other equipment. A repair shop and its facilities are usually incorporated in this area. The room should have sufficient base and wall outlets to serve both the workbench and power-equipment needs.

Recessed wall shelving and cabinet storage should be provided for tools, supplies, and equipment. This space should also contain hot and cold water, a slop sink, a lavatory, a water closet, and a clothes closet.

The floor should be concrete and should be pitched to a central drain. The junction of the floor and wall should be coved.

Custodial Storage Rooms A supply closet equipped with a slop sink and space for mops, pails, brooms, and cleaning supplies should be centrally located on each floor level.

NEIGHBORHOOD RECREATION BUILDINGS

The neighborhood recreation building will include many of the features of the community recreation building, as previously described. The neighborhood building, however, is usually intended to serve a smaller number of people. The size of the facility will ordinarily fall into the Type III (under 10,000 sq ft) or Type II (10,000 to 20,000 sq ft) classification. In all cases, the building should be so designed that rooms can be easily added.

NEIGHBORHOOD SERVICE CENTERS

By ROBERT PERLMAN and DAVID JONES

A neighborhood service center may be defined as a conveniently located facility, staffed by professional workers and community residents with no training, designed to provide specific and speedy services to people with a wide variety of simple and complex problems. On the philosophical level, the centers comprise one important element of a broad attack on crime and poverty. On the action level, they are one way of dealing with problems of inhabitants of the inner city, a "place to go" for help.

Services dispensed by centers may range from on-the-spot advice on problems requiring immediate attention to long-term assistance with legal, employment, and personal problems. In addition to furnishing these services, a growing number of neighborhood centers are planning for, and implementing, programs designed to mobilize neighborhood groups to participate in decision-making processes that directly affect their lives, to become a vital force for social change. These centers feel that they must not only help to resolve specific problems but must also work to correct those faults in the society that create these problems.

Those who have developed and worked in such centers are generally very enthusiastic about this "new" way to deliver services. National organizations, as well as local, governmental, and voluntary agencies, are becoming increasingly interested in utilizing this particular organizational device.

The goals of the center are to promote and facilitate effective involvement of neighborhood residents in the solution of neighborhood problems and to improve the quality of programs which are designed to aid the elimination of poverty. As such, the neighborhood center is the focal point of the local community action program in a neighborhood.

A center can gather and share information about new and existing programs. It can deliver the resources of many public and private service agencies to those who need them. It can coordinate the programs and services of these agencies to answer the needs of the individual and the total community. At the same time, it can work to modify and enrich existing programs and services so that they respond more effectively to the unique poverty problems of the neighborhood.

In order for the center to have effect on the elimination of poverty, it must belong to the neighborhood it serves. It must be what the people want it to be. It should be a place where people will want to go, not simply because they can get free medical treatment or legal advice but because it is a comfortable, familiar, friendly, and exciting place to be.

The neighborhood center's most important function is to provide the people of a neighborhood with a structure and a program design to enable them to act. The center should help people gather and use their own resources as well as those in the community at large; it should help them develop the competence to

work in their own behalf toward the resolution of the social and economic problems of poverty in their neighborhood.

The first step in planning a neighborhood center is the determination of the neighborhood to be served. The best way to decide if a given geographical area is a neighborhood is to discover if the people in the area think of themselves as being neighborhood residents. In Appalachia, a neighborhood may be a "holer" or a "creek." In the South, a rural town and the surrounding farms may be a neighborhood. In cities, a neighborhood could be one or more public housing projects. In many cases, the definition of the neighborhood may be so obvious a consideration that it demands very little thought. It may simply be the section of town where poor people live.

It is important that neighborhood centers be placed in more or less distinct neighborhoods. Some consideration should be given, however, to the size of the population served. Harlem is a neighborhood, but it clearly cannot be served by just one neighborhood center. As a general rule, a center that serves more than 35,000 people will probably be too large for effective neighborhood communication. On the other hand, some neighborhoods will be too small for a full-scale facility. In such cases, particularly in sparsely populated rural areas, nearby neighborhood centers may consider placing outposts to perform outreach and referral functions and to provide communication with the center and other service groups.

Another important consideration in the determination of the neighborhood is the transportation system, public and private, in the area to be served. The neighborhood center should be located within easy reach of area residents or should develop its own transportation system to bring itself as close as possible to the people it serves.

Determining the Neighborhood Needs

The second step in planning a neighborhood center is the determination of the area's particular needs. Local conditions and the expressed desires of neighborhood residents should be the most important considerations. Asking simple questions of a number of residents is one way to get the necessary information.

The processes of neighborhood involvement and participation can develop in the people served by a neighborhood center an active concern about services by making the programs, both existing and locally initiated, respond directly to needs that they themselves have indicated.

Responding to Neighborhood Needs

Once the neighborhood's unique mix of needs are pinpointed, arrangements should be made to decentralize into the center existing programs which can meet these needs. Written agreements between the service agency and the center can govern the terms of each decentralization. These agreements should clearly define the organizational chain of command within the neighborhood center: what kind of

program will be offered, and what procedural and other changes are agreed to by both parties in operating the program through the facilities of the center.

Programs must not be imposed on neighborhoods but should grow out of expressed neighborhood needs and the capacity of neighborhood people to use them. Where no existing program can adequately respond to definite neighborhood needs, the center may want to develop and operate new programs.

Decisions about what programs and groups will operate through the center will help determine the physical requirements of the facility. At the present time, centers vary in size and function from single-deck referral units to highly complex, specially designed facilities incorporating a wide range of services. There is no single model.

In an urban environment, the neighborhood center may operate out of a single storefront, from many offices scattered throughout the area, or from a cluster of buildings. In a rural environment, where transportation is more difficult and neighbors are more widely dispersed than in cities, certain variations may be more feasible.

Rural Variations

In rural areas, the neighborhood center may be a system of facilities on wheels, a fleet of service buses that continually travel from place to place within the area served by the center. Operating from a small administrative center, one kind of mobile unit can travel throughout a county, spending a day or two every week or every other week parked near a neighborhood of poor people. Such units may serve only for recruitment, intake, diagnosis, and referral to nonmobile, nondecentralized services. They may also take the form of single-purpose units. Mobile public health units are an example of a traveling single-purpose service that has proved successful in many areas. The eventual goal should be truly multipurpose units which go where the poor are and serve as many of their needs as possible. Mobile units do not have to operate from a single administrative center. Another variation involves carrying programs, on a rotating schedule, to a number of neighborhood centers scattered throughout the service area. These centers may be located in abandoned schoolhouses, old homes, grange halls, church halls, or other available space which has been turned into an appropriate facility. Each of these in-the-field centers would have a skeleton staff of resident workers who would do outreach work on a full-time basis.

The individual community will have to decide which of these models is most appropriate to local conditions. For many communities, a combination of the two may be the most workable solution.

Some typical service programs could consist of the following:

The Housing and Rent Clinic would advise and assist tenants on their problems, conduct housing inspections and verify complaints, and work with city agencies on the prompt handling of housing problems.

Neighborhood Service Centers, Office of Juvenile Delinquency and Youth Development, U.S. Department of Health, Education and Welfare, Washington, D.C., 1967.

Tenant and Block Organization and Education would help existing tenant groups identify and act on problems, conduct conferences and training sessions on tenants' rights, emergency action, self-help techniques to improve apartments and evaluation of urban renewal needs, and would organize new groups.

Coordinated Processing of Housing Service and Community Facilities, Complaints, and Requests. The central offices of the neighborhood boards would coordinate complaints on housing and requests for public facilities and take them up with city agencies, maintain records, and conduct studies of the effectiveness of city services.

Housing Repair and Maintenance Service. A nonprofit corporation would repair and rehabilitate housing, employing (and training) youth and unemployed adults as the labor force.

Consumer education clinics would help people get the most for their money by providing information through lectures and the distribution of written material. *Parents workshops* would assist parents to understand the school system and encourage them through group discussions to take a more active part in working with the schools for the education of their children.

Employment services would primarily offer information and referral to appropriate sources of jobs and training.

A Health Conservation and Education Unit would assess the health needs of residents, develop programs to meet them, and facilitate the delivery of the city's health services.

Ancillary services would consist of social services and legal services. *Social services* would provide counseling to individuals and families on a short-term basis—for example,

a dispute with an employer or getting a child reinstated in school—and long-range help with such problems as material and child-rearing difficulties. Teams of indigenous workers would operate under a supervisor. In addition, there would be homemakers and home technicians to help with management of family budgets, to provide temporary child care so that mothers can keep appointments at other agencies, and an escort service for the aged. There would be special educational programs for unwed parents, with a particular effort to involve fathers; a service for the aged and isolated; and the use of mental health resources on a contractual basis.

Throughout, referrals would be made to these programs by the neighborhood staff and there would be a referral program to facilitate coordination within the centers and with other community agencies.

Governmental and Public

EMBASSIES

DESIGN CONSIDERATIONS FOR OFFICE BUILDINGS

The building character should express:

- Its representational and office building nature
- The nature of the building in terms understood by and compatible to the host country
- Quality without ostentation or luxury
- A deference to local architectural tradition and materials

General planning should include:

- Easy and direct pedestrian access and egress, including provisions for the physically handicapped.
- Easy vehicular access and egress with provision for adequate visitors, and staff parking along with the necessary service access to building. Shelter should be provided at main entrance for protection during inclement weather.
- Arrangement of public spaces for convenient service to the public.
- Arrangement of sensitive areas remote from public.
- Efficient circulation employing maximum use of double loaded corridors.
- Provision for building expansion either vertically, horizontally or both.
- Physical security of building by perimeter walls and/or fences, setbacks from property lines, exterior lighting, easy control of entrances and visual control of stairways and elevators.

Climatic and local considerations include:

- Humidity
- Dust control
- Extreme temperatures
- Insect control
- Sun and inclement weather control
- Earthquakes
- Flooding

The Basic Space Module

The basic space module of 75 sq ft represents the normal space allocation for individual desk personnel engaged in clerical activities. Increments of this module will provide offices of proper size for individuals or groups having other functional space requirements. Thus, an office of 150 sq ft will accommodate a single reporting officer or two clerk-typists; an office of 225 sq ft will provide for an officer of supervisory rank, two secretaries, or three clerk-typists. The 75-sq-ft module thus establishes a means by which the building can be systematically designed for flexibility of partitioning to suit space needs.

The typical single office of 150 sq ft represents a preferred room shape of 8 ft 8 in. wide by 17 ft 6 in. deep. These proportions have been proved to accommodate required furniture for one or two persons depending on rank and function. Similarly for offices of larger size, furniture and space needs will be satisfied if the 17-ft 6-in. depth is retained uniformly and the widths are varied in accordance with net area requirements.

Dimensional Limitations

The following represent minimum clear ceiling heights. Adjustments may be required in some instances to accommodate specific requirements.

Classified conference room	10 ft
Classified mail and communications space	10 ft
Mechanical space	Varies — to be ascertained in each case
Typical office space	9 ft
General storage areas	10 ft

Planning Flexibility

The following space standards are established for purposes of planning consistency and cost control and for these reasons should be adhered to. This does not preclude variations where such are necessary to provide for special requirements at a particular post. In addition to specific space variations, the site and locale may dictate that the service functions may preferably be located in a structure separate from the office building.

SPACE STANDARDS FOR EMBASSY OFFICE BUILDINGS

The following net areas are recommended for the various typical embassy staff requirements and functions. Space variations between the class I, II, III, and IV posts are indicated under

the post classifications. An asterisk (*) indicates those functions or spaces requiring additional evaluation specifically to accommodate the special need at each post.

Office of the Ambassador

This section is a sensitive area and should be located on an upper floor and separated from the general public areas. Access to the ambassador's and deputy chief of mission's offices should be through and controlled by the secretaries' office. The reception area should be separate but convenient to the secretaries' office. (See Table 1.)

Political Section

This is a sensitive section which reports directly to the ambassador and should be located accordingly. (See Table 2.)

Economic Section

This section should be conveniently located for easy public access although not necessarily on the main ground floor except in the case of the commercial library. This latter function and any directly associated office should be immediately available to the public. (See Table 3.)

Consular Section

The size of this section will vary greatly according to the volume of the consular activity. At

TABLE 1 Embassy Space for Ambassadorial Section

	Class post, net sq ft			
	I	II	III	IV
Ambassador's office	600	525	450	450

	I	II	III	IV
Chief political section	375	300	225	225
Secretary	225	225	150	150
Political reporting officer	225	150	150	150
Reception area	225	150	150	150
Political officers (each)	150	150	150	150
Clerk-typists (150 sq ft first, plus 75 sq ft each additional)				

TABLE 3 Embassy Space for Economic Section†

	Class post, net sq ft			
	I	II	III	IV
Chief of economic section	375	300	225	225
Secretary-receptionist (including waiting area)	300	225	225	225
Economic reporting officer	225	150	150	150
Labor officer	225	225	150	150
Commercial officer	225	225	150	150
Others	150	150	150	150
Agricultural officer	225	150	150	150
Assistants (each)	150	150	150	150
Commercial library*	425	375	375	300
Clerk-typists (each)	75	75	75	75
Translators (each)	75	75	75	75

†Note: At some posts one of the above, such as agricultural, may be large enough to warrant a separate section.

some posts this work would be handled by one officer requiring one room; at others, the complete operation would require one or more floors and several waiting rooms. Its varied function is to process visas, citizenship, veterans' affairs, notaries, shipping, and social security. This section will require its own file room, its own waiting areas (for larger posts preferably two, one for immigrants and one for nonimmigrants), toilet facilities, fingerprinting facilities, confidential interviewing room, and mail storage boxes for American citizens. By its public nature it should be on the ground floor near the main entrance or possibly have an entrance of its own.

Only minimum areas are recommended here because of the wide variation between consular activities in and between classification of posts. Specific space allocations will be determined by need on an individual case basis. (See Table 4.)

TABLE 4 Embassy Space for Consular Section

	Basic minimum* net sq ft
Consular officer	225
Junior officer	150
Clerks (each)	75
Stenographers (each)	75

Two toilets for above	75
File rooms for immigrant or visa files	150
Vault (visa, notarial fees, etc.)	75
Veterans' affairs	150
Citizenship officer	150
Notaries	150
Shipping and storage	150

Administration Section

The operation of this section will not be confined to one area of the building but will be distributed throughout. The responsibilities consist of general housekeeping of the post, supervision of building personnel, post expenditures, message center or communications complex, maintenance personnel, Marine Guards, etc. The administration officer and

his immediate staff, especially those coming in contact with local businessmen and tradespeople, should be on the ground floor near the main entrance. The communications complex should be separate and in a more remote area, preferably near the ambassador, as it will contain the mail and file rooms, communications room, vault, and incinerator for classified material. This area will be contained in a concrete vault accessible through one controlled entrance.

Communications Complex* This facility is subject to changing requirements and to sharp variations between posts. Therefore, it is impractical to establish general space requirements. Instead, required areas will be determined by the department on a case basis for each building planned.

This function is to be designed and constructed in accord with "Minimum Physical Security Standards of Foreign Service Office Buildings" and should be located on the top floor remote from all public areas and access.

Photo and dark room	225	225	150	150
Storage area* (basement)	300	225	225	150

The communication complex will normally consist of the following:

- Ante and reading room
- Classified mail and file room
- Vault
- Incinerator
- Communication room(s)
- Office(s)
- Lavatory

Liaison Attaché

This section should be located on or near the top floor of the building, usually adjacent to the communications area. (See Table 6.)

Military Attachés (Army, Navy, Air)

This space will vary according to post. The post may have one or all three services represented. For the most part, this operation will be of a classified nature and should be remote from the public. In some posts the military attachés will have their own communication complex and vault. A photo laboratory may be required for each service. (See Table 7.)

United States Information Service

This section may not always be located at a post. It is also possible that this activity may be located away from the office building proper and in a more advantageous location in the midtown section. The library is the largest unit in the Information Service. Many posts include a projection room or theaterette for motion pictures. This activity should be on the ground floor or basement.

Since USIS activities often take place after hours, when the mission is closed, the service should have a separate entrance so that the rest of the building can be separated and locked for security reasons. (See Table 8.)

USIS Library The supervisors' offices should be 150 sq ft net and library assistants' offices should be based upon 75 sq ft per desk personnel required. Because of the extreme variation of the size of libraries between posts, it is impractical to stipulate standard spaces for the various library functions. Instead, the USIS space recommendations should emanate from the post and should be based upon an accurate survey of the need in each case. This need should be established by the number of volumes in the collection and the average peak number of people patronizing the library. USIS Library spaces include the following:

Roof Penthouse

On the roof may be located the elevator machine room and the building's air-conditioning equipment. Space for these should be allocated as required by equipment and need. (See Table 9.)

Garage or Parking Area

To the areas noted above there may be added garage facilities or outside parking, or a combination of both, depending on site. The following items are to be considered as necessary:

Parking area (x number of cars)
Wash and grease rack
Dispatcher's office
Chauffeur's dayroom and toilet
Bicycle racks
Underground gasoline storage tank (including pump)
Vehicle repair shop and tool storage

ACCESS RAMPS FOR THE HANDICAPPED

A ramp is defined as a sloping walkway which is attached to a building as a means of moving from one floor elevation to another without encountering any obstruction.

A ramp must be at least 4 ft wide. Ramp slopes must not be greater than 8.33 percent (1 inch in 12). (See Fig. 1.) If a ramp slopes 5 percent (1 inch in 20) or less, and there is no dropoff, then no handrail will be required. If ramp slope is greater than 5 percent, and there is no dropoff, then one handrail will be required. See handrail requirements in Fig. 5.

Ramps shall have at least a 5'-0" straight level surface at the bottom to allow stopping distance for wheelchairs. (See Fig. 2)

Ramps shall have a 3'-0" long intermediate-level platform at 30'-0" intervals for rest and safety. (See Figs. 3 and 4.)

Ramps shall have level platforms wherever they turn to allow turning and stopping space for wheelchairs.

An Illustrated Handbook of the Handicapped, Section of the North Carolina State Building Code, Ronald Mace, AIA, and Betsy Laslett, Raleigh, N.C., 1977.

TOILET STALL

A 5' x 5' stall is usable by most people and has the following requirements.

1. Stall must be 5 x 5 ft
2. W.C. center line is 1 ft 6 in from side wall
3. 32 in door diagonally opposite W.C.
4. Handrail extends 1 ft 6 in in front of W.C.
- 1 1/2 in O.D., 1 1/2 in from wall, 13 in above seat
5. Standard partition toe clearance

REGIONAL SHOPPING CENTERS

By LATHROP DOUGLASS, FAIA

BASIC HISTORY AND TRENDS

A shopping center is a complex of retail stores and related facilities planned as a unified group to give maximum shopping convenience to the customer and maximum exposure to the merchandise. The concept is not new. The agora of the typical city of ancient Greece was essentially a shopping center in the heart of the business district. The Emperor Trajan's architect, the Greek slave Apollodorus, built a shopping center adjacent to the Roman Forum in A.D. 110. It had a two-level enclosed and ventilated mall lined with open-fronted shops startlingly similar to today's most up-to-date concept. The typical Arabian *souk*, or market, of the Middle Ages also had narrow, weather-protected malls lined with open-fronted shops.

The past two decades, however, have seen such a tremendous development in planned shopping facilities in the United States that today's center has, in fact, become a new building type.

First, population growth led to outward expansion of the cities and the building up of the vast residential suburbs. Downtown congestion, due to increased car ownership and inadequate streets, weakened the downtown merchants and prompted them to set up branches in the suburban periphery in order to be more convenient to their customers. As a result of these activities on a large scale, a whole new industry was born. Each suburban district soon had its own major shopping center and several minor ones. Such districts each had clearly defined trade areas.

Another major change then set in: Vastly improved, high-speed circumferential highways soon tended to put all these suburban centers in competition with each other. At the same time, the decline of retail business and decay of buildings in the central business districts began forcing, in self-defense, a revitalization of downtown.

As a result of these two new factors, the shopping center industry is today pointing in two new, significant directions. First, the suburban centers are becoming megacenters, complete with several department stores, office buildings, motels, amusements, and, of course, parking facilities. Second, the central business districts are making a determined stand to counteract the ever-growing suburban competition by embarking on programs for construction of new high-speed connector routes to downtown and construction of major downtown renewal projects, also complete with stores, offices, hotels, amusements, and parking facilities, usually in decked garages due to the high downtown land cost.

TYPES OF CENTERS

Neighborhood Center (Suburban)

This is a row of stores customarily (but not always) in a strip, or line, paralleling the highway and with parking between the line of storefronts and the highway. Service is by

alley in the rear. Ranging from 20,000 to 100,000 sq ft of space, these projects usually contain a supermarket and a drugstore, often a variety store, and a half-dozen or more service-type stores. They cater to a very limited trade area and are not normally competitive with the major centers. A few of the newer of these centers have their retail units clustered around an enclosed "mini-mall."

Intermediate or Community-Size Center

This also is usually a strip of stores but substantially larger than the neighborhood center and usually containing a so-called "junior" department store as the major unit. This type is vulnerable to competition from the larger centers and hence has declined in desirability. The parking pattern is normally similar to that of the neighborhood center.

Regional Center (Suburban)

This contains one to four department stores plus 50 to 100 or more satellite shops and facilities, all fronting on an internal pedestrian mall, or shopping walkway. Parking completely surrounds the building group so that all stores face inward to the mall with their "backs" to the parking (Fig. 1).

With today's rising land costs and diminishing supply of suitable large tracts, there has been a growing trend toward double-decked parking to save land area. It is simply a matter of the relation between the land cost and the cost of the parking deck (Fig. 2).

There is also a strong trend toward double decking of the stores themselves so that the central pedestrian mall has two interconnecting levels, each lined with shops. The double-level mall is also due, in part, to the need to keep horizontal walking (shopping) distances within reason. As land costs continue to rise and projects to grow larger, three- and four-level malls will, no doubt, become common.

Renewal Projects (Downtown)

Because of their complexity in matters legal and political—as well as physical—downtown centers are still, to some extent, in the experimental stage. The trend is toward a close integration, on two or more shopping levels, of department stores, shops of all sorts, restaurants, etc. The multilevel malls may connect directly or by bridges to other shopping facilities, hotels, office buildings, theaters, and parking garages. Because of high land costs, all parking is normally multidecked and can be above, below, or, better, laterally contiguous to the shopping facilities. The downtown trend is toward a multilevel pattern interconnecting the essential parts of the central business district.

DEVELOPMENT AND FINANCING

Shopping centers are customarily promoted and owned by developers whose primary motive is a return on their investment and, to a lesser extent, by department stores or

ONE OF VARIOUS 4 DEPARTMENT STORE PLANS; 1 OR 2 LEVELS

■ DEPARTMENT STORE
□ SHOPS

Fig. 1

REGIONAL SHOPPING CENTERS

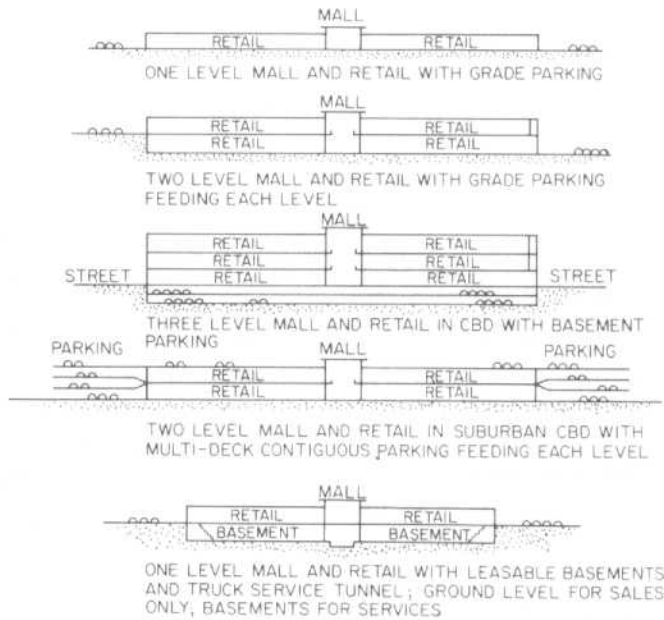

Fig. 2

other merchants who are looking for new outlets to increase their sales volume. With the advent of rapid inflation, there is also a strong trend toward participation in ownership by the institutions, such as insurance companies, who in the past confined their activity merely to lending money to the developer or merchant.

Customarily the developer, regardless of what individual or group he represents, can, with good judgment and skill, set up the project on the basis of, let us say, a 10 percent investment of his own money and the remaining 90 percent as a long-term loan from an insurance company or other institution. As the long-term loan usually does not become available until completion of the project, the developer borrows needed interim money, or short-term financing, usually from a bank. The dollar value of the long-term loan is primarily calculated as a multiple of the anticipated rent roll; that is to say, it is based on a certain number of times the total projected annual rent collectible from all the committed tenants who have acceptable credit ratings. As the loan is based primarily on the rents and, therefore, is not affected by overruns in the construction cost of the job, it is obvious that the construction budget becomes of utmost importance. With only, say, 10 percent of the total job cost as his investment and 90 percent borrowed, an overrun of 10 percent will, in actuality, double the amount of money that the developer must invest. Otherwise, he will have to sell out, go bankrupt, or cut every possible cost he can, even if it damages the popularity of the project. The vital importance, as a result of this pattern, of a realistic and inviolable budget should be clear.

THE TEAM

At the earliest possible stage in the concept of the project, preferably even before acquisition of the land, a developer, i.e., owner, should assemble his professional team. For a small neighborhood center, such a team might consist solely of the owner and the architect, especially if the owner is experienced in this type of leasing.

For today's regional centers and downtown renewal programs, however, the essential team involves, in addition to the developer (who may be an individual or a large development corporation), the architect; the market analyst; the leasing agent; the mortgage broker; the engineers (usually retained by the architect and including mechanical, structural, and site); the attorney; the public relations advisor; and other occasionally needed specialists. The larger and more complex the proposed project, the more necessary it is that each of these members of the team be experienced not only in his own profession but also in the specific field of shopping center development. It is desirable, in fact, that they participate, as part of the team, in major decision making.

THE ECONOMIC SURVEY OR MARKET ANALYSIS

Prior to any planning activity and often prior to acquisition of the land, the market analyst makes a complete survey of the anticipated trade area surrounding the proposed site for the center. The boundaries of the trade area customarily depend on acceptable automobile driving time to the center. Frequently the trade area is broken into a primary area, where a high percentage of the inhabitants would shop at the center, and one or more secondary areas where, due to competition or to driving times or other reasons, a smaller percentage would be anticipated. The analyst assembles data on existing population, future population trends, income levels, car ownership, existing shopping facilities and their probable future competitive effect, and also projected facilities already announced or likely to be announced by other developers. He estimates the probable mortality rate of these proposed projects—i.e., how many will never be built—and the competitive effect of any survivors. The analyst, from his available statistical records, and based on the income level, population, ethnic origins, and other characteristics of the trade area, then makes estimates of the amount of family income likely to be allocated to such categories as food, drugs, furniture, women's and men's

clothes, shoes, department store purchases, etc., etc.; and, from these estimates, he prepares charts indicating the recommended total amount of floor area to be built and how much of this floor area should be devoted to the various kinds of merchandise and services. These data then form the basis for the architectural planning. No major project should be undertaken without an adequate market analysis.

It is axiomatic that success goes to the developer who "gets there the fastest with the mostest," as the old saying goes. If the project is too slow in coming to fruition, a competitive center, securing a firm hold on the available business, may be built.

If a project is too large for the trade area, it cannot be sufficiently rented, and the unrented space may cause it to fail. If it is too small for the trade area, it will invite the construction of competitive centers and may lose out due to this competition. In the past this determination of size, i.e., total store area, was perhaps the most vital decision to be made and one that could be readily pinpointed from a thorough market survey by a firm of sound judgment. Today, however, with the vast increase in circumferential highways, it has been conclusively established that trade area boundaries no longer can be pinpointed. A surprising number of shoppers now take advantage of centers on the opposite side of a city because of the new high-speed peripheral highways. Today every aspect of a center's concept, planning, and design must be of the best for survival in the face of competition.

A school can be unfunctional, but the children still have to go to school. A home may have many bad features, but the family will still live there. Even a factory building can have its faults. A shopping center, however, depends on the whims of its customers, mostly female, for its success. If, because of inconvenience or unsuitable merchandise or for any other reason, it does not have the proper appeal, the customers simply will not go there to shop, and the project may become a failure.

SITE SELECTION

The following criteria normally apply:

- A site available for development and located within the trade area recommended in the market analysis.
- Location easily accessible to at least one existing or shortly to be constructed major highway, preferably to two or more major highways. A location literally bordering on one or more major highways is desirable for its advertising impact on passing cars, but this is not necessary if suitable access roads exist between the highway and the site.
- Adequate present and future capacity of adjacent highways for through traffic plus that to be generated by the center.
- Land cost in proper relation to total capital cost and to obtainable rents.
- Adequate size and suitable shape to permit proper planning of the merchandising area and a proper number of parking spaces. Where acreage is limited and high land costs are justified, parking can be on decks and the whole project can be multilevel.
- Zoning suitable for proposed use or at least a reasonable chance that such zoning may be obtained. Zoning changes are often difficult, expensive, and time-consuming to make.
- Utilities available or installable at acceptable cost.
- Subsurface ground conditions that can

REGIONAL SHOPPING CENTERS

be overcome at acceptable cost, such as rock, swamp, trunk sewers, streams, etc.

- * No easements or other legal restrictions that will interfere with proper planning.

- * Topography that will permit as near to an ideal plan as possible without incurring excessive grading or drainage costs. It is noted, however, that it is usually better in principle to move a million yards of earth than to compromise a plan that will give maximum customer convenience and proper store relationships.

Other criteria that are desirable but not essential include:

- * Adequate site area for future expansion and inclusion of supporting facilities, such as office buildings, motels, etc. There is little risk in the acquisition of such additional land, as land values always go up with the construction of a major center.

- * Proximity to public transportation (in the case of larger cities).

- * Possibility of integrating the land with other mutually beneficial uses such as town centers, recreation, housing, etc.

- * Protection of the project from undesirable neighboring developments through achievement of suitable zoning of adjacent land.

SCHEMATIC PLANNING

Following acquisition of the site and completion of the economic survey, it is customary for the developer to retain a suitably experienced architect who proceeds to work out, from the market survey and physical information pertaining to the property, a simple schematic solution. This shows building sizes and arrangement, gross leasable areas, malls and public space, parking layout, access roads, method of servicing, and other basic aspects of the concept, including all pertinent statistics. This material, in conjunction with the economic survey, is then used by the developer in approaching the department store prospects. The architect's work normally is suspended at this point until the department stores are committed. Many projects never go beyond this stage and, in any case, there is usually a substantial lapse of time before the project goes ahead.

The major principles of schematic planning, in addition to conforming to the leasable area recommendations of the economic survey, are (1) convenience and comfort for the customer, and (2) maximum merchandising potential for the tenant stores. Customer convenience demands ease of vehicular access to and from the site; ease and adequacy of parking; reasonable walking distances; simple, direct pedestrian shopping routes with minimum obstructions and inconveniences. It is axiomatic that a shopper rarely goes where there is inconvenience of any sort.

Maximum merchandising potential means the giving to each tenant in the project of a reasonably equal opportunity to capture a portion of the customer's trade. The means of achieving this is normally based on the concept of "anchors," or "pulls," that is to say, those merchandising units that have maximum appeal to the customer. The typical shopper is usually attracted to a center primarily by the type and range of merchandise offered by the major department stores. This appeal is supplemented by the opportunity for convenient comparison shopping in the many smaller or satellite stores. Because of the customer activity generated by the appeal of the department stores, these major units are spaced at strategic spots, such as at each end of a one- or two-level pedestrian mall

whose length is lined on each side with the smaller satellite stores. The flow of customers from these major units to each other then draws people past the smaller stores, where they stop en route for impulse and comparative shopping.

The key to this planning is the avoidance of any dead ends or out-of-the-way locations for the smaller stores and the concentration of all shopping on clearly defined routes connecting with major "anchors," or "pulls," i.e., the department stores.

Data on store sizes, mall design, parking layout, etc. are included in other sections of this article.

INTEGRATION WITH THE COMMUNITY

For many years the typical shopping center has been a low, flat building mass resembling an island surrounded by a vast, barren ocean of asphalt. Landscaping has been inadequate, and integration of any sort with the community has been completely lacking. With the competitive need, however, for increasing the size of centers and including within their general scope office buildings, hotels, housing, etc., the resulting more complex planning requirements have given rise to a better opportunity, as well as to greater urgency, for the true integration of the stores and parking within a larger major complex, such complex in turn properly integrated with the existing neighborhood. The importance of this integration has been emphasized in the concepts of the "new towns" arising in Europe and elsewhere. Plan integration with the neighborhood has, in fact, become a must for large centers and a factor not to be ignored even for the smallest ones. Such integration involves the space interrelationship between the neighborhood and project's buildings, roadways, parking, landscaping, and pedestrian walks. It can be a powerful means of assuring long-range future real estate values, both for the shopping project and for the entire surrounding community, whether commercial or residential.

Where land costs permit, it is obviously desirable to obtain control of the land surrounding the center, not only to protect the center but to take advantage of the inevitable increase in value and development potential of such land.

PLANNING FOR EXPANSION AND STAGED CONSTRUCTION

It has always been considered good practice to build retail space as nearly as possible commensurate with market survey recommendations. Today, however, two problems often confront the developer:

- a. With the increasing extent of peripheral highways and the spectacular growth of the suburbs in many cities, it has become increasingly difficult to estimate the future potential of a particular center and hence the amount of future space needed to maintain its competitive position.

- b. With the increasing number of centers with two to four department stores, the situation arises in which one or more such stores, however necessary they may be to the project and however eager they may be to be included, may for good reasons of their own wish an opening date a year or more later than the official opening date set for the center.

Therefore, it has become more and more customary to do either or both of the following:

- a. Plan for a more or less indeterminate expansion at some unspecified future date.

- b. Plan for one or more specific stages of construction, each to be undertaken as a successive part of a more or less continuous construction operation.

In the latter case, i.e., two or more specifically scheduled construction stages, the problem becomes more one of leasing than of planning. The project is planned for the final stage, and it becomes the leasing broker's problem as to how much space he can lease at top rents in the first stage and how much it becomes necessary to leave for the later stage or stages due to the initial absence of one or more department stores. There also arises the problem of the construction contract. If stage one is completed before stage two is sent out for bidding, then the bidding can be truly competitive. But when the second stage begins before completion of the first stage, it may be difficult to secure bids or to negotiate a reasonable price with the contractor already on the job. A method occasionally used on large centers, and one which applies in this situation, is for the general contractor or the owner's building organization to clearly establish that more than one subcontractor in each major trade will be utilized and thereby to ensure a continuing competitive atmosphere. This procedure also has the advantage of allowing smaller subcontractors to bid on parts of large jobs.

In the case, however, of providing for expansion at some *undetermined* future date, the situation is different and much more difficult to resolve. Merely to provide excess land area for future use is usually an unacceptable solution. This is because proper integration of the future unknown facilities with the existing center may turn out to be difficult if not impossible. This, in turn, weakens the trade potential of the overall enlarged project. The proper procedure usually is to master-plan the entire available site so that a thoroughly acceptable final project can result. It is noted, however, that any master plan for the enlargement of a center at some indeterminate time, say three years or more in the future, must in every case take into consideration the following:

The most critical time for any center whatever is the year it opens and usually also the succeeding two years of its life. It either becomes a success within those years, or it becomes, for the time being at least, a failure. Few developers with their small equity investment and high mortgage payments can afford to retain ownership of a losing operation for a sufficient length of time to take advantage of any ultimate success.

Therefore, the master plan for the site must provide for as nearly perfect an *initial* stage as is possible. If, then, in five or ten years the center becomes so popular that the developer decides to enlarge it, the center's popularity and sales potential are already clearly established and the perfection of the final plan is of much less importance.

Expansion of individual stores is a different problem. Special provision for such expansion may be made by (1) adding future floor(s), (2) lateral contiguous construction, (3) use of areas held in reserve for this purpose in basements and mezzanines, or (4) eliminating adjacent tenancies and taking over their space.

In all cases involving an increase in the project's gross leasable area (G.L.A.), added parking must be provided to compensate and maintain proper ratio of G.L.A. to car stalls.

Regardless of the program of phased construction or of future expansion, there are two additional items that must at all times be taken into consideration in any schedule:

1. A shopping center does by far its greatest

REGIONAL SHOPPING CENTERS

amount of business in the two months before Christmas. Its next busiest season is before Easter, and the next busiest, after that, is prior to "back to school." Therefore, shopping centers in general and department stores in particular customarily set opening dates that are inviolable. Any serious postponement can jeopardize the heavy investment in merchandise for that particular season. It is customary, therefore, in all shopping center operations to schedule the work *backward* from the mandatory and inflexible opening date and allow adequate time for fixturing and stocking the stores.

2. For public impact and general public acceptance in a shopping center's early years, it is generally desirable to schedule the leasing, planning, and construction so that *all stores can open at once*. This avoids the public inconvenience and bad public relations of a mall with many barricades, etc., due to unfinished stores, as well as the unfavorable customer reaction from limited merchandise.

GENERAL DESIGN AND PLANNING CRITERIA

Column Spacing

Significant dimension is along the mall as this involves the widths, i.e., frontages, of stores. Often used spaces are 20, 25 and 30 ft, with the last the most flexible. Dimension from mall to rear of store can be set by the most economical structural system. It is essential to arrive at the most economical structural system, as the roof is a major cost factor.

Store Depths

For one-story stores in America, buildings are usually 120 to 140 ft deep, sometimes more to accommodate larger stores. If there are basements or mezzanines, the depth dimension usually can be reduced 20 to 25 percent. In European centers and others with many very small stores, there is a problem in how to achieve shallow depth without incurring higher costs from greater mall lengths in relation to floor area. One often used and desirable device is to "dog leg," or "ell," a larger store around a smaller store.

Clear Heights

These vary from 10 to 14 ft or more, with 12 ft a good average. Above this clear height, there must be adequate space for air-conditioning ducts, recessed lights, structural system, etc.

Ducts and Shafts

The shells of the buildings must be flexible enough to accommodate any reasonable tenant requirements. It is essential that the mechanical engineer set up a schedule of the location and sizes of the principal duct runs and shafts to avoid serious future space problems. This requirement includes special exhaust ventilation through the roof and all other mechanical items that can be anticipated.

Central Plant vs. Individual HVAC System

Regardless of which method is used, the space to be occupied by all equipment must be determined, both in size and location, in the earliest planning stages. Central plant equipment can be in a separate building, on the project roof, or elsewhere so long as it is

economical as to design and length of runs. Individual plants in each store require roof space, cooling towers, etc.

Roof Equipment Concealment

The inexcusable eyesores so often seen can be avoided by proper coordination of work between the leasing agent, the architect, and the mechanical engineer and the resulting provision of properly located and designed roof screens and enclosures.

Exterior Walls

As these may have, depending on each store's requirements, service doors, public entrance doors, trash rooms, show windows, etc., a modular design that can suitably accommodate for visual effect any of these features is very desirable. Show windows and public entrances are rare on parking lot facades, as it has been found that the great majority of customers enter stores from the mall rather than directly from the parking lot. Public entrances from the parking lot usually occur only for department stores, for stores open on Sundays, and for such tenants as restaurants, drugstores, and the like.

Anarchy vs. Regimentation

In the original shopping centers, there often was no design control at all, with a resulting anarchy of signs, materials, and design. This situation gradually changed to one where so much rigid control was exercised that the projects became far too monotonous. Proper design calls for a homogeneous whole with the widest possible latitude for individual design of each store. Generally the greatest possible latitude (in good taste) should be given to the *mall* facades, with fairly severe restrictions placed on the *exterior* facades. This gives interest in the interior, where it is desirable, and unity of design for the exterior.

Traffic

The car capacity of all contiguous roadways used for ingress and egress must be sufficient to accommodate present and future through traffic *plus* the traffic generated by the shopping center. Proper signal controls, reservoir

lanes, divider strips, and other traffic control features must be provided. It should always be kept in mind that a center with, say, 5,000-car parking and an average turnover on Fridays of, say, four cars per parking space, accommodates a total number of cars per day that would stretch, if traveling in a line on the highway, all the way from New York to Boston. Because of the complexity of the traffic problem, the developer or his architect frequently hires a traffic engineer to assure himself that the highways have adequate capacity and that the center can accommodate smoothly the ingress and egress of customers' cars. The traffic engineer is, however, interested in speed and smooth flow of traffic, while the architect for the project should be more concerned with convenience, simplicity, and customer's freedom of choice in selecting her route and parking procedure (Fig. 3).

LEASING

Customarily the satellite stores and all other facilities, retail or otherwise with the exception of the department store, are leased by the developer. The developer may lease one or all the department stores and build them to the tenant's requirements, or he may sell or lease the land to one or more, in which case the department store designs and constructs its own facilities within the established limits and requirements of the overall project.

The satellite leases usually provide for a minimum annual rent (on which the mortgage calculation is based) plus or against an *overage* rent consisting of a percentage of the store's gross annual sales. It is the latter provision which makes the success of each individual store so important to the developer and which compensates him for future inflation. It puts the developer and tenant into a sort of partnership.

It is obvious that the individual rent terms must reflect not only the cost of the land and overall project costs but also the amount of special work done by the developer for the individual tenant. In the past, the developer installed much of the tenant's special requirements and received a proportionally higher rent. The trend today, however, is for the developer to supply the shell of the premises only, with each tenant installing at his own

TYPICAL RESERVOIR LANES, RING ROAD, AND PARKING SYSTEM
A = RESERVOIR LANES D = SECONDARY PARKING
B = RING ROAD E = FUTURE PARKING RESERVE
C = PRIMARY PARKING

Fig. 3

REGIONAL SHOPPING CENTERS

expense the ceiling and floor finishes, decor, mall storefront, and some of the air-conditioning equipment items. Trade fixtures, except in unusual circumstances, are always installed by the tenant.

As the leasing program takes time to consummate, it is absolutely essential that the leasing proceed *simultaneously* with the architectural design and drawings and that the leasing agent and the architect and his engineers keep in continuous communication. Otherwise, long delays and expensive changes ensue.

In view of the importance of the department stores in generating customer traffic for the project, their lease terms usually provide only a minimum (if any) profit for the developer. The profit on the development as a whole must then come from proportionately higher rents from the satellites. For this reason, when the owner of a center is a developer and not a department store, it is essential that at least half the total retail area be occupied by high-rent satellites.

TENANT MIX

Tenant "mix" is the name for the *plan* relationship to each other of the various types of stores and facilities. Proper tenant mix exposes the customer to a varying sequence of differing types of merchandise. If each store type is properly located in relation to every other store type, it has been demonstrated that each store will receive its maximum sales volume. In such cases, the center will be successful and all tenants, plus the developer, will profit. If the relationships are not correct, many of the stores may not receive their fair share of the customer's dollar, and both the individual store and the developer will suffer. The developer may not, in such cases, receive any rent based on percentage of sales volume, and the strength of the center as a whole will be weakened. There are many theories on proper tenant mix. It has been fairly well established, however, that with few exceptions and regardless of length of malls or number of mall levels, a generally *mixed* pattern of high and low prices, soft goods and hard goods, retail and services produces the best individual sales volumes and overall success.

THE MALL

The pedestrian mall has become the feature of today's shopping center, whether the project is in the suburbs or in the central business district. The pedestrian mall has the following characteristics:

- The mall usually consists of the principal mall, the major pedestrian shopping street of the project, and one or more subsidiary approach malls or access routes connecting the main mall with the parking areas or adjacent streets.
- With few exceptions, all stores have their principal entrance on the main mall or, less desirably, on approach malls, whether or not these stores have additional entrances to parking lots or adjacent streets.
- The mall can be on one level or on two or more superimposed levels. Each mall level should, however, avoid slopes or steps within its own walkways to avoid hindrance to shopping and a source of accidents.
- The mall can be (1) open, with weather protection consisting solely of continuous

canopies along the store fronts, (2) completely covered but open to the air, or (3) completely enclosed, necessitating heating in winter and air-conditioning in summer.

The trend has been almost exclusively toward the enclosed climatized mall except where weather conditions are ideal or some other factor makes the open mall preferable.

Enclosed malls have been in the form of huge courts; they have been wide, narrow, straight, circuitous, empty, or filled with amenities; they have had one level or two or more levels; and they have been lighted by skylights or solely by artificial means (Fig. 4).

The trend has been steadily away from wide malls and court-type malls. Currently widths of 30 to 40 ft are outnumbering widths of 50 ft or more. The wider malls require more land-

TYPICAL SECTION OF 2 STORY MALL SHOWING NARROWER LOWER LEVEL SOMETIMES USED TO GIVE BETTER VISIBILITY BETWEEN LEVELS AND INCREASE LEASABLE AREA.

Fig. 4

scaping and features to avoid a barren atmosphere. They also require more cubage and hence are less economical despite the possibility of high rents from kiosks and similar features spotted along their lengths. Furthermore, and most important, narrow malls facilitate back and forth comparison shopping from one side to the other and hence significantly aid the customer's exposure to the merchandise. A logical trend is toward stretches of narrow mall, generally devoid of amenities, punctuated by moderate-sized courts in front of department stores or elsewhere which become customer magnets. The courts have greater lighting intensity, greater height, and spectacular features such as fountains, lush landscaping, and monumental sculpture.

The length of malls generally should not be more than 800 ft (preferably less) between department stores or other major features; but, in the case of more than two department stores, total length can be substantially more.

Because of the high downtown land costs and increasing land costs in the suburbs, plus the shortage of sites of adequate area, the two-level mall is becoming a standard solution; in due course, malls of three levels or more will doubtless increase in number. Such multi-levels make the shopping area much more compact and walking distances shorter.

In connection with any two-level (or more) mall, it is virtually mandatory that *each level be as important as every other level*; otherwise, one level will become the level, all the stores will want to be on that level, and the other level will be second choice, will command lower rents, and hence, in all probability, will not economically justify its construction.

To achieve this equality of desirability, of customer appeal, and of rent balance, it is essential that both (or all) levels have:

- Equally convenient accessibility from parking areas by means of two or more levels of immediately adjacent parking, whether on grade or on decks or by means of other devices to equalize the parking convenience.

b. No mall dead end on any level without a department store as its terminus.

c. Adequate vertical transportation between levels, usually one or more sets of escalators and several sets of convenient stairs.

d. Visual interconnection of levels through the maximum use of open wells permitting maximum visibility of one level's shops and customers from the other.

MALL AMENITIES

With the advent of the pedestrian mall came the need to give it interest and glamour as an enhancement to the overall customer appeal of the center. This interest or glamour is normally non-income producing; but, in the case of small retail kiosks for such items as keys, stockings, photo supplies, and soft drink facilities, very high rents can be obtained because of the conspicuous and high-exposure locations.

Mall amenities generally include, in addition to landscaping, which will be elaborated on in another section, most of the following items:

- Trash and ash receptacles, a mandatory aid in preventing litter.
- Directories of one sort or another to facilitate finding specific stores.
- Public telephone installations.
- Seating groups and individual benches for resting, although many planners believe it is better to have frequent coffee stands both for better control and to produce income. Many also believe that, in downtown areas, it is often better to avoid benches so as to discourage loitering by undesirable elements.
- Fountains, properly designed for public protection from water hazards. (Water seems to have a universal appeal.)
- Kiosks of various sizes and shapes, generally less than 250 sq ft, though there is a trend to larger ones.
- Lockers (occasionally) for storing purchases while continuing to shop.
- Sculpture or other art forms as major design features.
- Miscellaneous items occasionally used to catch the public interest, such as birdcages, kiddie mazes, fashion mirrors, closed-circuit TV, clocks, continuous music, fashion platforms, exhibit areas, etc. It is noted that in the case of exhibit areas, it is necessary to provide adequate mall-access doors for bringing in large items to be exhibited.

Mall lighting should be low-keyed and incandescent, should lend interest to dark or monotonous areas, and should, except in major courts, allow the storefronts to be the main attraction. Natural light is often used in moderation to give variety of effect and sometimes to save power cost, but generally natural light must be limited in order to avoid dilution of the impact of the storefronts along the mall. As malls are customarily open late afternoons and evenings, adequate artificial illumination must be provided regardless of the extent of the natural light.

Mall materials are of great importance. Generally speaking, they should reflect the quality level of the project, be sturdy enough to resist vandalism, and require minimum maintenance. As an example, floor materials on projects vary from hardened cement to terrazzo, tile, or marble, and now, occasionally, to carpeting. It is noted that the floor of a mall is very conspicuous and the character, quality, and ease of maintenance of its surface materials should be primary considerations.

REGIONAL SHOPPING CENTERS

STOREFRONTS AND SIGNS ON THE MALL

Open malls require glazed storefronts, and hence their requirements are similar to those of the typical city street. Enclosed, climatized malls can have open storefronts, i.e., the major part of the store's frontage can be without show windows and completely open, so that the shopper can enter the store virtually without being aware she has done so. At night the store is protected by sliding glass panels or roll-up grilles.

Generally speaking, except for certain limitations on use of materials and, more particularly, on store signs, the tenant is encouraged to use as much imagination and variety in his store frontage as possible to give glamour, interest, and appeal not only to his own store but to the mall as a whole. Customarily the storefront as well as the store interior is designed by a firm retained by the individual store rather than by the developer.

Except for whatever devices are used to achieve overall unity and harmony, the mall frontage can be treated completely at the will of each tenant, subject only to such restrictions as are recorded in the lease terms. It is essential, however, that such terms give the developer and his architect the right of final approval at their sole discretion. Signs are primarily either for store identification or for general advertising of the store. The former has a legitimate place in the shopping center concept. The latter generally does not. The larger the store, the greater the justification for a sign, as the larger stores are the magnets that attract the public. Endless exterior signs for the smaller stores are confusing, unsightly, and useless to store, owner, and customer. The passerby cannot read the confusion of smaller signs, and the shopper who has already parked gets no identification value from small-store exterior signs as there is literally no way for her to relate any such sign to its own store once she has parked her car and entered the mall system.

Signs, on the other hand, are a necessity within the mall to identify the individual stores. Signs should be simple, easily grasped, in good taste, and so arranged as to be visible at close range as well as at a distance. Too often store identification to the passing potential customer is omitted in favor of huge signs legible only at a distance that may not exist. Properly designed and lighted signs can greatly enhance the interest and appeal. Sign regulations should accompany each lease, and all signs must be subject to final approval from the owner and his architect to ensure proper harmony.

Signs or pylons on the exterior to identify the shopping center itself are a common practice but of dubious value. A regional project with its half-mile of construction is so conspicuous that anything more than simple identification is usually unnecessary.

EXTERIOR FACADES

Some of the major satellite stores desire storefronts on the exterior of the complex, i.e., parking lot facades. The trend, however, whether by store preference for simpler control or by developer preference for economy, is to reduce to a minimum the number of show windows and public entrances on the exterior facade. Experience has shown that the public does not like to enter a mall through anything but the regular mall entrances or else through major

stores such as department stores. Furthermore, the whole theory of the present-day shopping center is to get the customers as quickly as possible into the mall, from which the shopping process originates. Department stores insist on having direct entrances on the parking lot as well as the mall, but here again, exterior show windows are usually cut to the minimum.

Even in the central-business-district projects, where some of the stores front on both city streets and the mall, experience has shown that the majority of the shoppers enter the stores from the malls rather than from the city streets, and many street entrances have been closed off.

In the matter of materials, the trend is toward permanence through good but not elaborate quality and the use of masonry and related types of material.

A major problem of recent origin that requires careful solution is that resulting from the fact that there may be several department stores, in addition to the satellite stores, each designed by a different architect. Achievement of harmony of design can, therefore, become difficult.

The problem of visible mechanical equipment is always a serious one. Mechanical design and drawings should always be carefully checked for visual aspects, and when such equipment is visible, consideration has to be given to suitable methods of concealment, whether by masonry screens or whatever.

SERVICING

Servicing involves the delivery of goods to the various stores and also the removal of trash and garbage. In the simple strip center, the servicing is customarily by an alley in the rear of the strip of stores. It is desirable to conceal the alley from adjacent neighborhood areas by a wall or landscaping.

In the one-level regional suburban center, servicing is customarily by one of the following:

a. Underground service tunnel, usually under the mall, connecting directly to tenant-leased basements which connect, in turn, to the stores above. This system avoids all unsightly trash, keeps parked trucks out of the way, and avoids allocation of prime parking space to servicing. It also relegates non-selling activities to the basement, reserving the main floor for sales. The tunnel adds, however, 3 percent or more to the total cost of the construction and more or less necessitates the inclusion of basements. This, in turn, calls for realistic leasing and financing of these basement areas if they are to be self-supporting financially.

b. Service courts on the periphery of the building complex. These are usually partially shielded from public view by masonry walls 6 to 10 ft high or higher. Their cost is minimum, but they occupy space that is expensive if land costs are high and that could otherwise be utilized for prime parking. The interiors of the courts are objectionable in appearance and can rarely be adequately screened. Furthermore these courts can usually be made directly accessible to only a portion of the stores present. This type of project normally has no basement space.

c. Over-the-curb and sidewalk directly from the street. This is the cheapest and uses the least land, but it requires rigid enforcement of cleanliness by the project management, delivery of merchandise and removal of trash

generally before or after business hours, and the mandatory inclusion of trash rooms in each store.

Generally speaking, markets, department stores, restaurants, and drug and variety stores have the greatest demand for adequate service facilities.

Service trucking routes on the site are often separated from customer routes, but this arrangement is generally not necessary as the relatively few number of trucks per day in a typical shopping center presents no traffic problem. In the case of sidewalk delivery, the parked trucks pose problems, and policing may be required to prevent the accumulation of trash.

In multilevel projects, the use of strategically placed freight elevators is necessary. These usually connect to fireproof passages at the rear of the stores (whether on an upper level or below grade) and often serve also as fire exits. With this type of project, necessitating service corridors, service courts can usually be fewer and more concentrated.

Mezzanines are occasionally used to provide storage and non-selling space. Such facilities have value in that they reduce the depth of space required and hence the land occupied, but they rarely produce savings in construction cost because of the need for greater height of store-building roofs for adequate clearances.

CLIMATE CONTROL

Today virtually all commercial space such as stores, offices, hotels, and pedestrian malls are maintained the year round within certain limits as to temperature and relative humidity. In most climates this means heating and humidification in the winter, cooling and dehumidification in the summer, and at least ventilation in the intermediate seasons.

The problem of cooling is proportionately more important than heating, even in relatively cold climates, because of the necessity to compensate for the body heat and moisture emitted by crowds of people and the heat from electric lighting, especially the incandescent type. It is not uncommon, even in the north, for the cooling system of a department store to operate almost into the winter season.

When this climatization of commercial space began to be adopted in the earlier shopping centers, it was frequently a matter of tenant choice and expense. The developer would supply the minimum heating required by the code, and each tenant would then decide whether or not to install his own air-conditioning system. This method is still used in neighborhood strip centers. As air-conditioning became more universal, however, it became logical for the developer to take advantage of his stronger buying position and have the air-conditioning installed on his own account as individual systems in each of the stores of his project, charging each tenant enough more rent to compensate for the cost and having each tenant responsible for operation and maintenance. Compressors and fans, as well as "cooling towers" required in the case of larger stores, were installed in basements, on mezzanines, and on roofs. Roof installations, necessary both for lower cost and engineering requirements, became large and unsightly. This led to efforts to concentrate the equipment as much as possible and to surround it with lightweight or, preferably, masonry screen walls creating penthouses on the roofs. With this system of

REGIONAL SHOPPING CENTERS

air-conditioning, each tenant always paid the retail electric rate applicable to the service required by him.

In the late 1960s, a new trend set in for the larger regional centers. The developer and his mechanical engineer found they could profitably work out a system involving a central cooling and heating plant for the entire project, metering and selling chilled water and hot water to each of the tenants and, of course, providing complete air-conditioning and heating for the mall and other public space. In this type of operation the developer installs the central plant, all the equipment for the mall, and the distribution lines for the heated and chilled water to the individual tenant spaces. Usually each tenant and/or store owner then installs the heat exchanger, fans, and distribution ducts within his own premises. The developer buys electric power at low rates because of the large amount purchased, and the individual tenant pays the developer for the water used at a lower rate than that which he would have had to pay in the case of his own individual plant. However, the tenant still pays enough to allow the developer to make a profit on the overall central plant operation. Because of this demonstrable and sometimes very substantial annual profit from the sale of heated and chilled water, the developer can finance the central plant so that it does not increase his equity investment. This had not been true before the 1960s.

In some states the developer can go even further and set up a so-called *total energy plant*, producing the electricity itself by means of gas or other fuels. Such systems are, in effect, private utility companies and subject to state law.

Should the developer wish to stay out of the problems of negotiation with tenants and operation of the central plant, there are companies that will undertake, for suitable remuneration, the construction, operation, and ownership of the system on behalf of the developer. In this case, it is obvious that financial and engineering responsibility of the operating company must be clearly established.

It is always *essential* that design provision be made in the earliest stages of the planning for all items of mechanical equipment, with allowance for floor space, for weight, for ceiling clearances, and for suitable visual effects of supply and exhaust grilles, especially in malls.

PARKING AND TRAFFIC

The need for parking was one of the primary factors leading to the development of the shopping center concept. Provision of adequate and convenient parking is, in fact, a basic requirement of any shopping center, regardless of its size or location. In suburban areas where almost all the trade comes by automobile, a ratio of between 5 and 6 car spaces per 1,000 sq ft of leasable store area is mandatory. In the central business district, where mass transportation and walk-in trade can be counted on for a substantial part of the clientele, the ratio can go down to as low as 2.5 to 3 cars per 1,000 sq ft.

In strip centers, customer parking is generally between the roadway and the line of storefronts.

In regional suburban centers, the parking normally is on grade and completely surrounding the shopping complex. Where land costs approach the cost of parking decks, it is be-

IDEAL LOCATION FOR HEDGES (3 FT. MIN. HEIGHT) TO CONCEAL "OCEAN OF ASPHALT."

SPACING FOR CONTINUOUS TREE HEDGE

COMPACTED MASS OF TREES FOR SCALE EFFECT

SIMPLE CONTINUOUS HEDGE FOR CONCEALING "OCEAN OF ASPHALT."

Fig. 5

coming more frequent to deck at least a portion of the site area, often where topography aids the situation.

In central-business-district projects, because of very high land cost, the parking usually has to be multidecked and is preferably contiguous, connecting directly with different levels of the center. It can also, for further economy of land use, be above the retail floors on decks as roof parking; or, more customarily, it can be below the retail levels in basement or partial basement locations. Though basement parking is the least desirable from the viewpoint of the shopper's normal psychology and is also least desirable from the construction cost point of view, it is a relatively common arrangement due to inadequate land area and to the legal aspects of the federal urban renewal programs. In such programs, in order to conserve land area and cost, the developer frequently can build the complex on air rights over multidecked garage facilities built by one or another government agency.

It has been stated by authorities on the subject, however, that for customer acceptance it is better to have parking above grade, even up to six or eight levels, than to have it more than one or two levels below grade.

In the matter of parking layout, car stalls can be set at angles (say, 70°) to the lanes, which then requires *one-way* traffic; or stalls can be at 90° to the lanes, permitting *two-way* traffic. The former is easier for the actual positioning of the car in the stall but more complicated and inflexible for the customer, due to the one-way pattern. Although both are commonly used, the 90° arrangement is somewhat more frequent for grade parking whereas the angled system is more customary for garages and decks.

Parking lanes, including the stalls on each side, range from 60 to 64 ft in width for 90° parking and from 56 to 58 ft for angled parking. In any decked parking layout, it is important that deck widths be multiples of these standard dimensions. Otherwise, wasted deck area substantially increases the cost per car of the parking without any offsetting advantages. In the case of multi-use central-business-district structures, the proper column spacing, requirements of parking, merchandising, offices, and hotel use vary considerably, and the planning becomes very involved. Practical decisions must be made as to which facility governs, and in no case must the "tail be allowed to wag the dog."

In the typical shopping center, parking is provided by the developer. In the case of central-business-district renewal projects, however, parking may be provided by a parking authority, renewal agency, or others. It may or may not be leased to the developer, or it may be built by the developer and leased to a parking authority or others.

In the case of double-level malls in the suburbs, topography can be an aid rather than a hindrance through provision of on-grade parking at two different levels—one parking area at the level of the upper mall, the other at the lower, thus equalizing the parking access and convenience for each level of the mall.

There are a number of ramp systems for decked parking and various patterns of parking lanes or bays for both ramped and grade parking. In the case of grade parking, lanes or bays should generally be at right angles to the building facades to enable shoppers to walk directly to the building complex without threading through parked cars, as with lanes parallel to the facades.

REGIONAL SHOPPING CENTERS

LANDSCAPING

This visually important element of shopping center design rarely receives the attention and budget its importance deserves. Most suburban customers have gardens and are landscape-conscious. Nevertheless, there are literally hundreds of shopping centers that are surrounded by barren oceans of monotonous asphalt. The primary reason for this situation is that the landscaping is installed last, is not related directly to the building construction operation, and consequently is vulnerable to "corner cutting" by the developer, especially if the project cost is running over the budget.

The landscaping in the regional, that is to say, suburban center usually has two components: interior, i.e., the landscaping in the mall, and exterior, i.e., that outside the buildings and in the parking areas. Because of the climate control in the typical enclosed mall, tropical planting can be maintained provided that adequate light, water, and drainage are supplied and there is proper maintenance. Although mall landscaping should not be luxurious to the point of blocking views of stores and interfering too much with cross-mall shopper traffic, mall landscaping can become a very powerful attraction to shoppers and provide a great deal of advertising and public relations value. When conditions are not suitable for living plants, good results can sometimes be obtained with properly fabricated artificial material.

For the exterior landscaping of the project, the principal problems are (1) the budget; (2) proper scale and effect in relation to the buildings; (3) suitable maintenance, including the problems involved in snow removal; (4) the necessity for obtaining maximum visual impact the first year of the center's operation.

As to this last item, the developer is not so concerned with how the planting will look in 10 years because the first 3 years of the center's operation are the most critical. It is during those years that everything must be at its best, and success is or is not established.

As to scale and effect, it is obviously difficult to obtain satisfactory results when a building mass may be as much as 2,000 ft long and only 20 ft high, and where vast acres of parking must be laid out with maximum convenience for those parking their cars (Fig. 5).

The following basic criteria, if used with imagination and a reasonable budget, can produce maximum effects for minimum costs:

a. Mass effects through close spacing of several trees or bushes in clumps or rows. Better to group five trees a few feet apart than to spot them *singly*, such as at ends of parking lanes, where they will be lost visually.

b. Concentration of the planting near the buildings where it will have the most effect, and not on the periphery.

c. Use of long lines of hedges (*not less* than 3 ft high, and of inexpensive plant material if necessary) wherever the parking pattern will permit. The hedges cut the line of sight from the normal eye level at 5 ft and, especially inside a car, at 4 ft. If the hedges are properly located, they can effectively conceal from view large areas of the parking pavement. This can go a long way toward preventing the "sea of asphalt" effect.

d. Installation of the maximum-sized plant material the budget will permit. Better to omit parts of the planting and use cheaper varieties of material than to have to wait 10 years for the plants to produce the proper effect.

As the regional centers must grow larger, more complex, and more glamorous to maintain their competitive positions, the quality and extent of the landscaping on future projects should steadily improve.

LIST OF STORES BY LOCATIONS

For reference purposes, the alphabetically arranged lists below represent a check list of stores that the Council¹ considers are suitable for the several categories of real estate location in shopping areas.

No. 1 Locations (100 Percent or "Hot Spot")

1. Bakery
2. Boys' clothing
3. Candy store
4. Children's wear
5. Cosmetics and perfume
6. Costume jewelry
7. Department store
8. Drugstore
9. Five and ten
10. Florist
11. Gift shop
12. Girls' apparel
13. Grocery (cash and carry)
14. Handkerchiefs and handbags
15. Hosiery shop
16. Infants' wear
17. Jewelry
18. Leather goods and luggage—(depends on ability to pay high rent)

19. Lingerie
20. Men's clothing
21. Men's furnishings
22. Millinery
23. Novelties
24. Optical shop
25. Paperback book store
26. Photographic supplies and cameras
27. Popcorn and nuts
28. Prescriptions (may not be possible because of drugstore)

29. Restaurant
 30. Shoes, children's
 31. Shoes, men's
 32. Shoes, women's
 33. Sportswear, women's
 34. Tobacconist
 35. Toilet goods
 36. Variety store
 37. Women's wear
- The following shops may go equally well in either No. 1 or No. 2 locations:

1. Cafeteria
 2. Dry goods
 3. Newsstand
 4. Service grocery
- No. 1 locations should be held largely for shops that keep open on certain common nights.

No. 2 Locations (Near the 100 Percent Area)

1. Art store and artists' supplies
 2. Athletic goods
 3. Auto supplies
 4. Bank
- A bank should not be in a no. 1 location, as it has limited open hours and when closed has a deadening effect on adjacent shops.
5. Bar (liquor)
 6. Barber shop (basement in the no. 1 location)
- When deciding on width of a barber shop, consider carefully the number of lines of barber chairs in order that space will not be wasted.
7. Beauty shop

J. Ross McKeever (ed.), *The Community Builders Handbook*, Urban Land Institute, Washington, D.C., 1968.

¹ Community Builders Council of the Urban Land Institute.

8. Bookstore
9. China and silver
10. Cleaners and dyers (pick-up)
11. Cocktail lounge
12. Corset shop
13. Delicatessen (also in no. 1 location in some cases)
14. Electrical appliances
15. Fruit and vegetable market (should be considered in relation to regular grocer)
16. Glass and china
17. Laundry agency
18. Linen shop
19. Liquor store
20. Maternity clothes
21. Pen shop
22. Radio and television
23. Sewing machines and supplies
24. Sporting goods
25. Stationery and greeting cards
26. Telegraph office
27. Theater (or no. 3 location)
28. Woolens and yarns

The following shops may go equally well in either no. 2 or no. 3 locations:

1. Gas, power, and light company offices
2. Ticket offices
3. Toy shop

No. 3 Locations

1. Army goods store (or in no. 4 location)
 2. Art needlework shop
 3. Baby furniture
 4. Building and loan office
 5. Chinese restaurant
 6. Christian Science Reading Room (or second floor in no. 2)
 7. Dance studio (or no. 4 location)
 8. Doctors and dentists
- Doctors and dentists are not favored in central locations. Janitorial expense for doctors' offices is at least twice as high as for ordinary office space. Also, they are hard tenants to please as to maintenance.
9. Drapery and curtain shop
 10. Electrical equipment and repair
 11. Express office (a popular service that helps build up a retail area)
 12. Furniture (pays low rent per square foot)

13. Hardware
14. Health foods store
15. Hobby shop
16. Interior decoration
17. Ladies' and men's tailor (or second floor in no. 1 or no. 2 locations)
18. Mortgage loan office (or second floor in no. 2 location)
19. Office supplies and office furniture (pays low rent per square foot)
20. Optometrist and optician (or no. 1 or 2)
21. Paint store
22. Photographers (or second floor in no. 1 or no. 2 locations)
23. Piano store (low rent)
24. Pictures and framing (low rent)
25. Post office
26. Power and light offices
27. Real estate offices (or no. 4)
28. Shoe repair
29. Tavern
30. Ticket offices
31. Travel bureau (or no. 2 location)

No. 4 Locations

1. Automatic family laundry service
2. Bowling alleys
3. Carpets and rugs, oriental
4. Diaper service
5. Dog or cat hospital (without outside runs)
6. Drive-in eating places
7. Radio and television broadcasting station

REGIONAL SHOPPING CENTERS

By VICTOR GRUEN, AIA*

The shopping center is one of the few new building types created in our time. Because shopping centers represent groupings of structures and because of the underlying cooperative spirit involved, the need for environmental planning for this building type is obvious. Where this need has been fully understood, shopping centers have taken on the characteristics of urban organisms serving a multitude of human needs and activities.

SELECTING THE SITE

Location

For the purposes of this discussion, the term "location" indicates the general area in which to select a shopping center site. The merits of location, whether the land has already been acquired or is being sought, must always be subjected to careful economic analysis. If the site has already been acquired, the economist directs his study toward the economic characteristics of the location in an effort to decide whether the particular property should be developed as a shopping center project, and if so, what its size and character should be. If the site has not yet been acquired, the economist must make a study of the general area within which the most suitable location can be pinpointed. This over-all study may involve as large an area as the metropolitan area of a large city.

First, an analysis is made of the total available economic potential of the general area. The search is gradually narrowed down through analysis of various segments of the larger area; a specific area within the chosen segment that seems to offer the most advantageous potential is then examined, and finally, a defined location within this specific area is chosen. If properly undertaken, this procedure will usually establish the most suitable location for a shopping center.

Inherent in any economic analysis is a study of the following factors:

- Population
- Income
- Purchasing power

- Competitive facilities
- Accessibility
- Other related considerations.

Attention must be paid not only to the existing population but also to prospects for future growth, which may be forecast by reference to past growth rates, the trend of population shifts, and the availability of remaining suitable land for residential development.

Population

In forecasting the population trend for ten or fifteen years, consideration must be given to such factors as existing population density, zoning restrictions, physical or man-made barriers to the development of new residential areas (mountains, waterways, industrial areas, public parks, cemeteries, airports), and other land uses that would forestall residential development.

The composition of the population in the trade area, as far as racial or economic characteristics are concerned, is important in various regions of the country.

In areas where strong traditions or prejudices exist, it may be unreasonable to expect that various ethnic groups will shop together. Also, it is unreasonable to expect that persons of low- or middle-income groups will patronize a high-quality type of shopping center or, conversely, that persons in the highest income groups will shop generally in centers that feature medium- or low-priced merchandise.

Trade area

The term "trade area" is normally defined as "that area from which is obtained the major portion of the continuing patronage necessary for the steady support of the shopping center."

The defining factors used in delineating a trade area vary from center to center. They include, but are not limited to, the size and influence of the proposed retail facilities, planning and design characteristics, travel time to and from the location, the existence of natural or man-made barriers—such as railroads and rivers—that

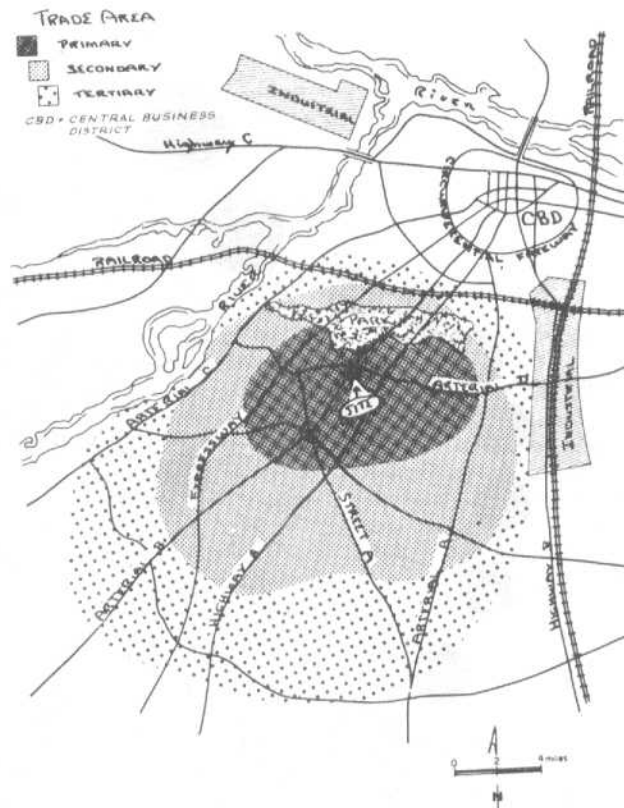

Fig. 6. Schematic plan of a shopping center location

Shown in the plan are trade areas, means of access, and various barriers to accessibility.

* The illustrations and certain other material in this section have been reprinted, with permission, from *Shopping Towns USA* by Victor Gruen and Larry Smith, published by Reinhold Publishing Corp., New York (1960).

REGIONAL SHOPPING CENTERS

would limit accessibility either in fact or psychologically, and the existence of competitive facilities. Thus the trade areas for various locations will not necessarily assume similar sizes or shapes (Fig. 6).

Site qualifications

It is important that the land to be used possess, to the greatest degree possible, the following qualifications:

1. The site must be located in the most desirable general area as established by the economic survey.
2. The site must be owned or controlled by the developer, or offer the possibility of acquisition.
3. Land cost must be in keeping with over-all economic considerations.
4. Existing zoning must permit shopping center development, or a reasonable likelihood of rezoning must exist.
5. The site must contain sufficient land to permit construction of facilities to meet the sales potential.
6. The land must be in one piece, free of intervening roadways, rights-of-way, easements, major waterways, or other ob-

stacles that would force development in separated portions.

7. The topography and shape of the site must permit advantageous planning and reasonably economical construction.

8. The surrounding road pattern and accessibility must allow full utilization of the business potential.

9. The structure must be visible from major thoroughfares.

14. Surrounding land uses should be free of competitive developments, and, if possible, should be of a nature that enhances the operation of the shopping center.

Rarely will a site completely fulfill all the above requirements, and advantages will have to be weighed and balanced against shortcomings. If the site already exists, it is sometimes difficult to separate the affection an owner may have for it (because of family sentiment or other reasons) from the hard facts of suitability, but it is well to remember that most poorly operating centers in the United States are located on just such "accidental" sites. It is, of course, possible that an existing site

may also fulfill the standard requirements, but determination should be made only after the same thorough scrutiny and analysis that would be given to a site to be purchased.

The following list indicates the relative importance of various considerations in site selection:

Location (value of 50)	Value
Population within 1 mile—quantity	5
Population within 1 mile—quality	3
Population within 5 miles—quantity	7
Population within 5 miles—quality	4
Population from rural area—quantity	2
Population from rural area—quality	1
Pedestrian traffic shopping at adjacent stores	4
Pedestrian traffic nearby for other purposes	3
Public transportation	5
Automobile traffic—quantity	4
Automobile traffic—availability	4
Direction of population growth	7
Area (value of 15)	
Size of plot	15

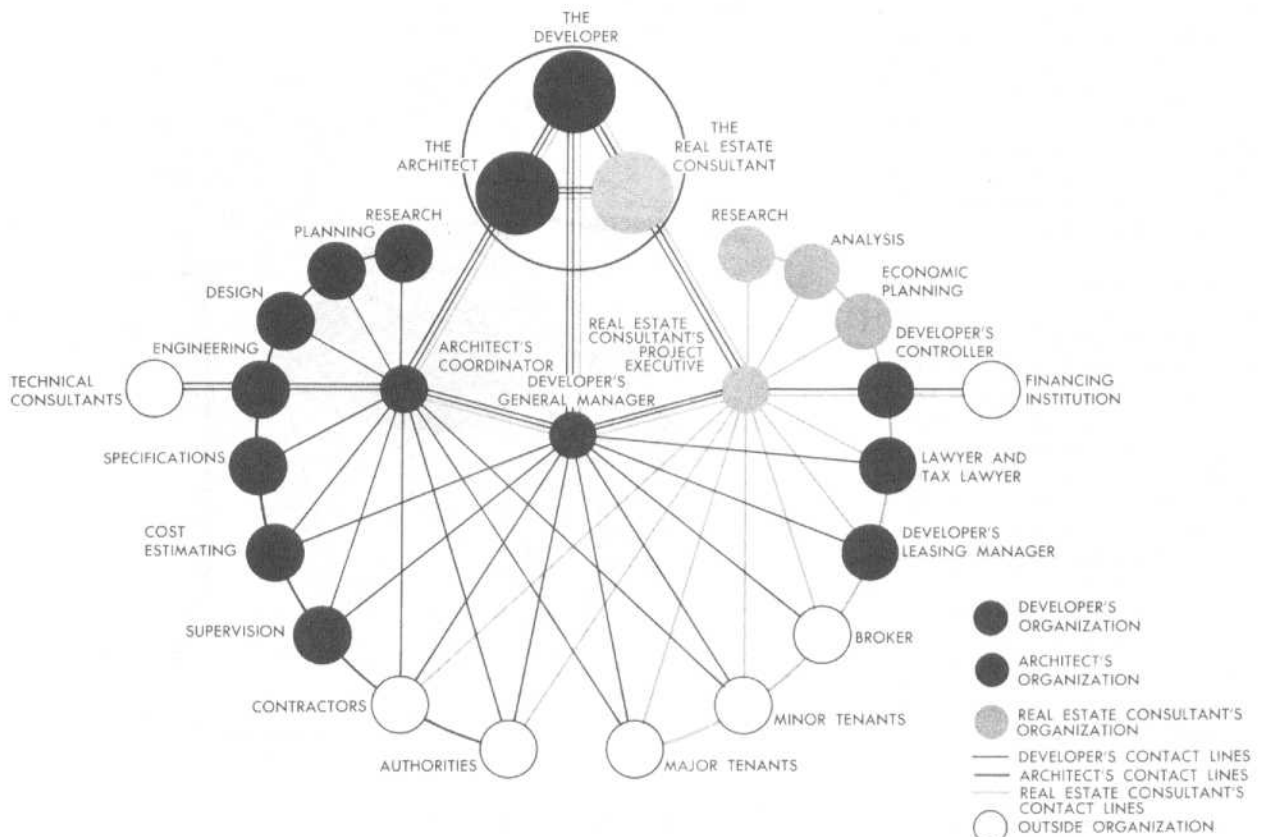

Fig. 7. The planning team

REGIONAL SHOPPING CENTERS

Cost of utilities and drainage	2
Visibility	3
Surrounding areas	2
<i>Availability (value of 10)</i>	
Ease of acquisition and time	6
Cost	4
	100%

ZONING

Contrary to nineteenth-century precepts of strict separation of industrial and residential land, brought about by rapid industrialization, most progressive planners and zoning boards today recognize that not all types of nonresidential activities are necessarily undesirable in predominantly residential areas.

The modern shopping center that integrates commercial, business, entertainment, and cultural facilities within a carefully planned framework, separates various modes of traffic from one another, and provides for the protection of surrounding residential areas from any objectionable uses, has made a significant contribution in this direction.

The developer may encounter any of the following zoning conditions:

1. The site is commercially zoned, or zoned for a "lower" use, in which case there is no problem.
2. The community has not yet adopted a zoning master plan, and the local planning board is willing to grant suitable zoning.
3. The entire site area is zoned residentially, or only a small portion, usually a narrow strip along the highways, is zoned for commercial use. The owner will then have to apply for rezoning of all or part of the site.

THE PLANNING TEAM

Depending on the size and complexity of the project, the planning team might, in neighborhood and intermediate centers, consist of the developer, the architect, and in some instances, a leasing consultant or lease broker. In projects of greater complexity and size, such as regional shopping centers, it may be well to add to the team an experienced consultant in real estate matters, well versed in shopping center economics (Fig. 7).

THE PLANNING SCHEDULE

Shopping center planning is a lengthy process in which each step must logically follow from the previous one. Impatient or snap decisions may result in catastrophe. First, a tentative planning and construction schedule is outlined which may be divided into five phases:

- Exploratory phase
- Preliminary phase
- Final planning phase
- Construction phase
- Opening phase.

For regional centers, each of these phases is likely to be clearly defined and even subdivided into various stages; for smaller centers the activity may be consolidated into fewer stages.

1. *Exploratory phase:* All pertinent circumstances and conditions are thoroughly probed, and the conceptual image of the shopping center is established.

2. *Preliminary phase:* Negotiations with major tenants and financing institutions are undertaken, and necessary adjustments are made. Preliminary drawings indicating all architectural and engineering aspects are completed. Preliminary specifications are written, and a reliable preliminary cost estimate is arrived at.

3. *Final planning phase:* Working drawings and specifications are completed, establishing a reliable basis for competitive bidding and for construction. Building permits are obtained. Invitations to bid are written.

4. *Construction phase:* Contracts are awarded. The architect is engaged in general supervision, supported by clerks-of-the-works who are usually retained by the developer. The architect chooses materials, selects colors, and integrates landscaping and art work. The developer and the economist are active in completing leasing, getting the center on an operational basis, and preparing for the opening.

5. *Opening phase:* The opening is an important event that calls for imagination as well as careful planning. In recent years, shopping centers of varying size throughout the country have been opened with ceremonies ranging from the quiet, unobtrusive opening of a few stores at a time, to mass opening ceremonies lasting for several days and featuring various kinds of attention-getting promotions.

Timing

It is difficult to estimate the time periods necessary for each phase of the planning

schedule, because of fluctuations in size and complexity of the project, availability of major tenants and of financing, climatic conditions, and the like. The following tabulation gives time ranges for regional projects proceeding under normal conditions:

	Time span, weeks
<i>Exploratory phase</i>	
(26 to 56 weeks)	
Feasibility study	8 to 12
Conceptual planning stage	4 to 6
Presentation stage	4 to 8
Development stage	10 to 30
<i>Preliminary phase</i>	
(10 to 22 weeks)	
Adjustment stage	4 to 10
Consolidation stage	6 to 12
Final planning phase	20 to 30
<i>Construction phase</i>	
(62 to 114 weeks)	
Bidding	4 to 6
General building construction	52 to 100
Tenants' building—interior construction	6 to 8
Total for planning and construction	118 to 222
	(27 to 51 months)

For intermediate centers (100,000 to 300,000 sq ft), a reasonable time span is 18 to 40 months; for neighborhood centers the span, depending largely on tenant availability, is likely to range from 12 to 24 months.

SPACE ALLOTMENTS

The architect's work starts with the planning of the site. For this task he must have at his disposal the findings of the economic analysis establishing the total rental area that can be supported by the shopping potential, broken down into main merchandising categories. He must have some idea of other uses to which the land should be devoted, and an idea of other probable zoning problems. On the basis of feasibility studies, he now has a general idea of traffic and accessibility, as well as full information about physical conditions of the site (including a topographic survey) and, as a result of test borings, about soil conditions. Sometimes he also knows the basic requirements of the potential major tenant or tenants.

With this information, he begins planning by carefully allocating portions of the land to specific uses. These uses fall into seven basic categories:

REGIONAL SHOPPING CENTERS

Fig. 8. Strip center with curb parking

Fig. 9. Strip center with off-street parking

Fig. 10. Double-strip center with off-street parking

Fig. 11. Mall center with only one magnet

Fig. 12. Mall center with magnet centrally placed

Fig. 13. Cluster-type center

Fig. 14. "Inverted" center

1. Structures
 - a. For retail purposes (retail areas)
 - b. For service purposes (heating and air-conditioning plants, electric substations, maintenance shops, truck roads, loading docks, and equipment storage)
 - c. For other commercial uses (offices and recreational facilities)
 - d. For public use such as civic and social facilities (community center, auditorium, exhibition space, and children's play areas)
2. Car storage areas
 - a. Surface parking lots
 - b. Double-deck or multiple-deck garages
3. Pedestrian areas
 - a. Malls, courts, lanes, and plazas
 - b. Covered pedestrian areas, such as public corridors and covered malls or courts
4. Automobile movement areas

Distribution road system on site
5. Public transportation areas

Bus roads, bus terminals, and taxi stands
6. Buffer areas

Landscaped areas separating car storage areas or service areas from the public road system, or areas separating parking areas from one another or parking areas from service areas
7. Reserve areas

Portions of site to be held in reserve

for the planned growth of the shopping center.

SITE PLANNING PRINCIPLES

The allocation of space for these and possibly other uses should be guided by certain planning principles in order to attain the highest feasible productivity of the land over an extended period of time: (1) Safeguard surrounding areas against blight; (2) Expose retail facilities to maximum foot traffic; (3) Separate various mechanized traffic types from one another and from foot traffic; (4) Create a maximum of comfort and convenience for shoppers and merchants; and (5) Achieve orderliness, unity, and beauty.

Foot traffic

Exposure of all individual stores in a shopping center to the maximum amount of foot traffic is the best assurance of high sales volume. Suburban business real estate often has been evaluated on the basis of passing automobile traffic—an evaluation which overlooks the fact that automobiles do not buy merchandise. It is only after the driver of even the most expensive car leaves it and becomes a pedestrian that he can become a buyer. Therefore, if shopping centers are to prosper, dense foot traffic must be created. "Shopping traffic," the act of walking from store to store, creates the lifeblood of a

shopping center; and proper circulation of this shopping traffic ensures business success.

Bearing in mind the relative importance in each instance of the size of the center, the shape of the site, the character of the tenancy, and other related circumstances, it is possible to weigh the advantages and drawbacks of various types of site planning to achieve the desired foot traffic. The manner in which site planning can influence the quantity of shopping traffic is illustrated in the schematic plans (Figs. 8 through 14) discussed below.

The degree of completeness of the separation between transportation and pedestrian areas depends on the size of the shopping center. In a single commercial building, this separation becomes effective only after the customer has entered the store. If there are two buildings, it might be possible to arrange a separated pedestrian area between them. The chances to create separated pedestrian areas are slightly higher in an intermediate center. In a regional center, complete separation is almost always possible and should be effected. Even in the smallest grouping of stores, such as a neighborhood center, it is possible to achieve a certain amount of separation by means of broad sidewalks with landscaping, low garden walls, and the like.

Strip center with curb parking (Fig. 8): In this plan, the shopping center is comprised of a row of stores extending 2,000

REGIONAL SHOPPING CENTERS

ft along the highway. The shopper parks at the curb in front of the store, transacts his business, and then is likely to enter his car and drive off. Shopping or foot traffic is limited.

Strip center with off-street parking (Fig. 9): This shopping center consists of a 2,000-ft-long row of stores set back from the highway sufficiently to permit parking in front. The sidewalk, or covered walkway, encourages foot traffic along the store fronts. This plan generates a certain amount of shopping traffic and thus is clearly superior to the type shown in Fig. 8. Shopping traffic is nevertheless limited, chiefly because of the 2,000-ft distance between the extreme ends of the strip. The shopper may return to his car after each transaction and drive to the next store on his list, ignoring intervening merchants.

Double-strip center with off-street parking (Fig. 10): Here, the strip is divided into two rows of stores, facing each other along a pedestrian mall, with parking on four sides. A "magnet" (department store, junior department store, or other major tenant store) is placed at each end. The 2,000-ft strip of stores is now divided into two 1,000-ft-long strips. With the distance between the two magnets now only half as great, foot traffic will be greater and the intervening stores will profit accordingly. Also, the creation of a highly desirable pedestrian area shielded from the noise, smells, confusion, and hazards of automobile traffic will contribute to greater shopping traffic.

Mall center with only one magnet (Fig. 11): In this plan, the existence of only one magnet, located at the extreme end of the pedestrian mall, reduces shopping traffic because of lack of interchange. The stores farthest from the magnet will participate very little in the traffic it generates.

Mall center with magnet centrally placed (Fig. 12): The arrangement of the pedestrian mall is the same as that shown in Fig. 11, except that the magnet is moved to a center position on one side of the mall. This modification represents a considerable improvement over the previous example.

Cluster-type center (Fig. 13): The major tenant is placed in the center of a cluster arrangement. Nearly all stores thus become neighbors of the most powerful shopping-traffic puller.

"Inverted" center (Fig. 14): This type exemplifies what might be called the "inverted" center, in which all store fronts are turned toward the inside of the building cluster. Entry into individual stores directly from the parking lot is diminished

or completely excluded. Shopping traffic is funneled through a limited number of entrance arcades into pedestrian areas—a plan that markedly increases the density of shopping traffic and controls its direction.

Separation of traffic types

1. *Pedestrian from transportation:* The separation of pedestrian areas from transportation areas is one of the cornerstones of good planning. The constant movement of vehicles within transportation areas inevitably creates a certain amount of danger, noise, fumes, and confusion, which distract the shopper and diminish shopping enjoyment.

2. *Service from customer traffic:* Service traffic in shopping centers represents a considerable portion of mechanized traffic. Even in the smallest shopping center, service vehicles for deliveries, pick-ups, garbage and trash collection, repair crews, construction and fixture contractors, and utility companies create a significant portion of the over-all traffic. Separation of service traffic from customer traffic is essential and may be accomplished on one or two levels.

Service areas on the merchandising or ground level in the form of truck roads, service courts, and other types of loading facilities, are practical in the neighborhood and intermediate centers. Good planning principles demand that such areas be properly shielded by screen walls or landscaping and that service vehicles be able to enter or leave without interference from automobiles or pedestrians.

Service areas on nonmerchandising levels permit the most productive space to be totally freed from service functions. Only the large center can achieve this separation, for which there are a number of possible arrangements. The truck tunnel under the shopping center mall is an expensive solution that is more talked about than used. Service roads located at the basement level provide a less expensive solution and are widely used. Where subsurface or topographical conditions make the construction of basements impractical, service and storage areas may be placed above the merchandising level and connected to it by ramps.

3. *Public transportation from customer traffic:* Separation of public transportation from customer traffic is essential. The designer must also consider the space needs for public transportation. Generous arrangements for public carriers with well-located and well-protected waiting areas will encourage transportation companies to

use them. Space requirements for existing and future public transportation facilities should be discussed at the outset of site planning work, and if possible, provisions should exceed the required minimum. Storage space for buses should be provided on or near the site so the transportation company can make extra facilities available for peak periods, especially at closing hours.

Orderliness, unity, and beauty

The concept of orderliness, unity, and beauty is a major planning principle; it must be applied to every major and minor aspect of the project, and must permeate all architectural expressions. Landscaping, signs, the architecture of structures, architectural treatment of spaces between structures, composition of structures in relation to one another, colors, and materials—all must adhere to this vital principle.

PLANNING THE SURROUNDING AREA

The term "surrounding area" can be understood either in its narrowest sense, that is, strips of land on the opposite side of the public roads adjoining the shopping center, or in its widest sense: the entire community within which a shopping center is located.

A reciprocal relationship exists between a shopping center and its surrounding area. A well-planned center can exert a highly invigorating influence on the area surrounding it, while a well-planned surrounding area can add in large measure to the prosperity of the center. Conversely, a poorly planned or unplanned commercial grouping of stores can have a deteriorating effect on its surrounding area, while the success of even the best-planned center can be endangered by a poorly planned or blighted surrounding area. The degree to which effective planning can be applied depends on the general location of the center, the size of the center, the investment policy of the developer, and existing zoning and economic conditions.

In general, if the site for a shopping center is the one remaining piece of land within a completely built-up area, there will obviously be meager possibilities for influencing the character of the surrounding area. Shopping centers in such areas usually operate under the handicap of having to be fitted into existing area and traffic conditions. On the other hand, one should consider the undoubted advantage of being provided with a fully developed buying potential.

REGIONAL SHOPPING CENTERS

Fig. 15. Original zoning plan

The plan shows zoning conditions as they existed when the original shopping center was projected.

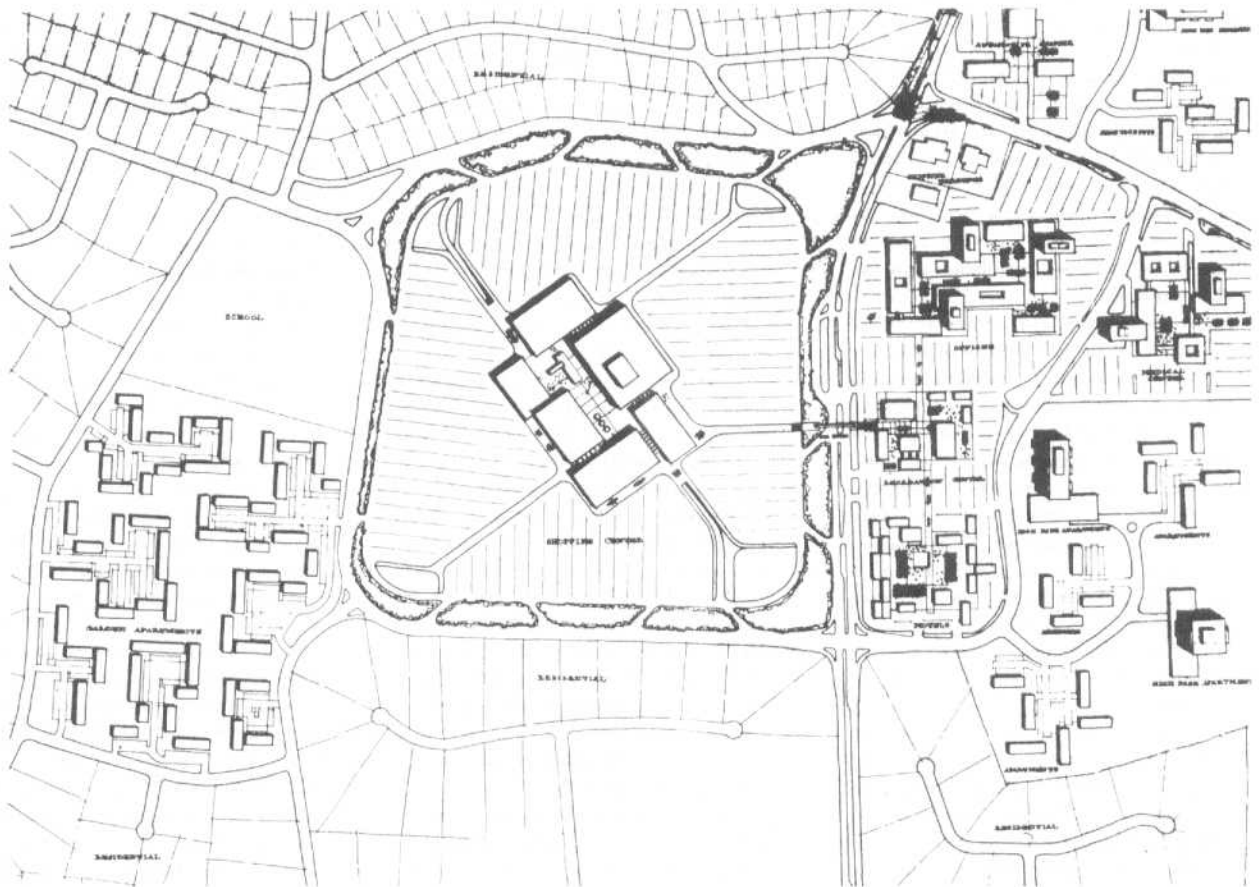

Fig. 16. Revised zoning plan

The plan represents the architect's suggestions for the surrounding land use for the same shopping center shown in Fig. 15. The revisions ensure control of the surrounding land by the developer.

REGIONAL SHOPPING CENTERS

Most shopping centers do not fall into this category since it would be rare to find a sufficiently large site for such construction within a fully built-up area. Large tracts of land can usually be found only on the fringe of suburban developments or in comparatively empty areas between suburban growth. This fact applies especially to the large regional shopping center and, to a lesser degree, to the intermediate one. With some planning, however, both types can create sufficient pulling power to reduce the disadvantage of being at some distance from densely populated areas.

The greatest opportunity for effective planning of surrounding areas in relation to the shopping center is afforded when new communities are projected. Then it is often possible to set aside, in the master plan, sites of ideal size.

Whether the shopping center developer

acquires surrounding land with the intention of developing it himself, or intends to negotiate with the owners of such land in order to persuade them to develop along the lines of best common interest, it is important to make a comprehensive plan for the land use of the surrounding area (Figs. 15 and 16).

PLANNING FOR EXPANSION

Planning for expansion should be considered if the shopping center is located in a steadily growing area. In such a situation the department store and other major stores will often express the desire to enlarge when their sales volume reaches a stated figure.

In order to make planning for expansion feasible, certain prerequisites must exist. The carrying potential of surrounding public roads must be sufficient to absorb

additional traffic loads. The site must be large enough to permit the developer to hold space in reserve for additional building, parking, and traffic areas; alternatively, additionally created income must be such as to justify capital investment for double-deck or multiple-deck parking structures at the time of enlargement. Most important, the developer must be reasonably certain that the growing buying potential of the area will not be more efficiently served by existing or future competition. For example, if suitable shopping center sites exist within the trade area, the likelihood of such future competition is great. These and other related factors must be carefully considered before making a decision to plan for expansion.

If it is decided to plan with a view to expansion, certain measures must be taken. Since the desire of department stores and other major tenant stores for growth is

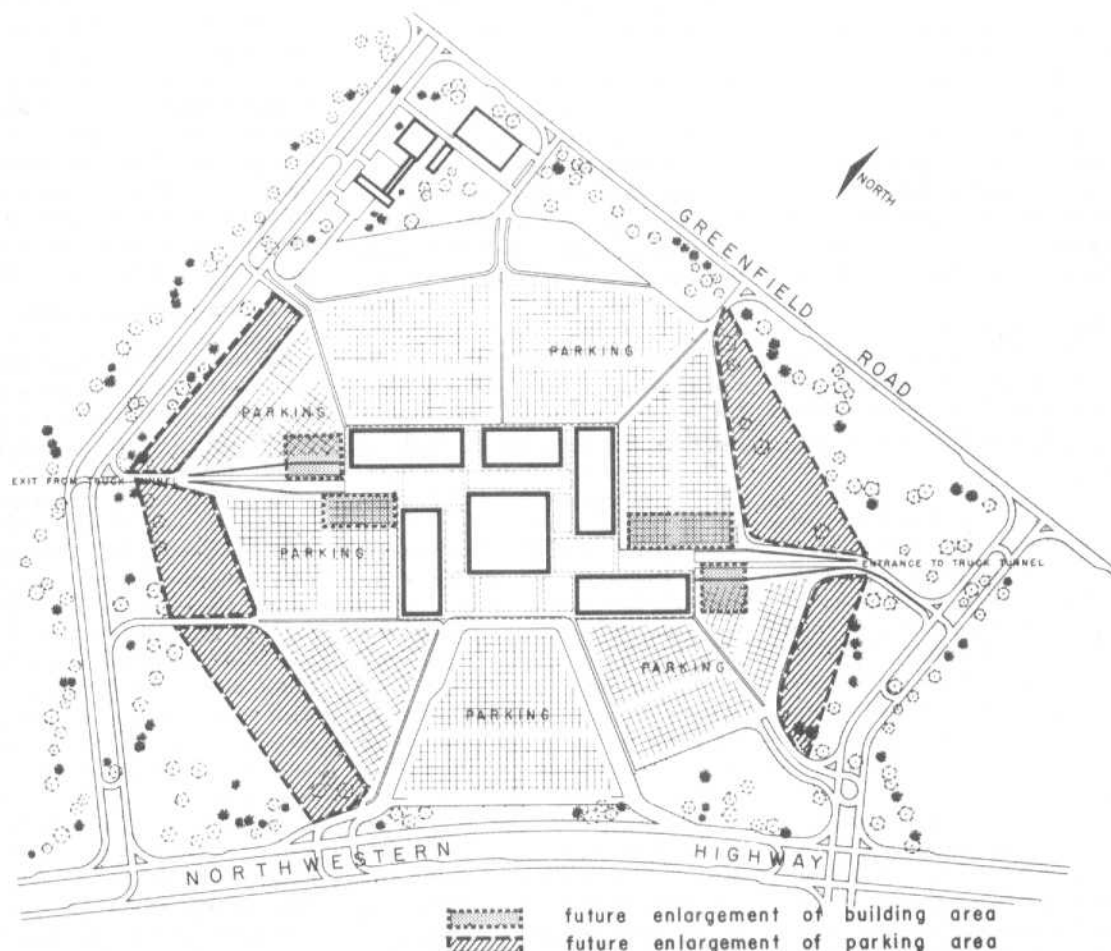

Fig. 17. Plan for expansion

Northland Center, Detroit; Victor Gruen Associates, Architects.

REGIONAL SHOPPING CENTERS

usually best met by provisions for vertical additions, the construction of larger foundations and heavier columns as well as roof slabs strong enough to carry future floor loads are required. Horizontal growth is difficult to accomplish without destroying the relationship between shopping center buildings and other elements. Land must be held in reserve for the enlarged parking needs that will be created by expanded shopping facilities. When the original construction is completed, these reserve areas will have to be properly landscaped in order not to mar the over-all appearance of the center. Central air-conditioning and heating-plant structures must be dimensioned to provide space for additional equipment, and all underground utility lines should be of sufficient size to meet ultimate needs. The general plan shown in Fig. 17 indicates existing structures and provisions for expansion.

PLANNING FOR DEVELOPMENT IN STAGES

Planning for development in stages should be considered if the shopping center site is located in an area that has not reached its ultimate population potential and if a quick acceleration of population growth may be expected. Another motivation for development in stages may be the desire of a land owner to make some immediate use of his land even though full utilization will be practical only in future years.

Planning for development in stages can be successfully accomplished only if a total master site-use plan is completed before construction or even detailed planning of the first stage is undertaken.

TRAFFIC

Traffic planning, an integral part of planning the site and the surrounding area, plays an important role in the proper functioning and success of the shopping center. It should be borne in mind, however, that the shopping center is not to be planned to serve traffic; rather, traffic is to be planned to serve the shopping center. Basic traffic planning concerns the planning team as a whole and the architect in particular.

Before the site is finally decided upon, serious consideration must be given to its accessibility. It is essential to gather all information about existing roads and the traffic-carrying capacities of the surrounding road system, as well as to establish the expected additional traffic load generated by the new shopping center.

Although the architect will avail himself of the assistance of a traffic engineer, the

specialist should not be expected to furnish basic concepts but should assist the architect in finding solutions within the framework of general and specified planning aims. Traffic planning is the responsibility of the architect since it is part of the general planning of the center.

Aims of traffic planning

1. *Easy traffic flow on surrounding road system.* The existence of enterprises that would result in a constant entering and exiting of cars along the roads opposite the shopping center would disrupt the flow of traffic and is therefore highly undesirable. (This is one reason why proper planning of the surrounding area is so important.) The existence of many side roads opposite the shopping center would also interfere with good traffic flow. The planner's main task is to see to it that automobiles can enter the site without slowdowns.

2. *Effective transfer of road traffic onto the site.* If automobiles were driven directly from an adjoining highway onto parking-lot lanes, chaos would result. The circulatory road that functions as a turn-off lane from the highway, making possible a gradual change of speed from fast-moving traffic to slower parking-lot traffic, plays an extremely important role.

3. *Even and effective distribution of traffic on the site.* The customer should be free to drive to any of the parking areas that surround the center so that he may come as close as possible to the store where he will make his first purchase. Secondary traffic movements within the parking area must be facilitated. In larger centers, arrangements must be made to guarantee the easy flow of circulatory traffic, avoiding any interference with pedestrians walking to and from the center's structures.

4. *Convenient and efficient arrangement of car storage facilities.* The aim of the parking-lot layout should not be to achieve the greatest possible number of parking stalls, but rather to ensure the greatest possible turnover of cars during a given period. Parking capacity is a valid measuring stick only if it denotes the number of conveniently arranged and dimensioned parking stalls.

Walkways for pedestrians will result in greater safety for shoppers and will eliminate the slowing down of vehicles, but will reduce the number of parking spaces in any area. Surfacing of good quality will speed parking and reduce maintenance costs. Lanes should be clearly numbered with signs visible to the motorists when entering the lot as well as when returning from shopping. Proper illumina-

tion is essential for safety and speed of parking operations.

No formula for proportioning parking area to sales area is recommended. Existing successful shopping centers provide from 3 to 9 car spaces per 1,000 sq ft of rentable area; however, each project must be decided on its own merits. An allowance of 400 sq ft per stall, including drives, walks, and landscaping, is recommended. Wide stalls arranged at a 45-deg angle permit the fastest and most comfortable parking. The maximum size recommended for a single parking lot is 800 cars.

5. *Separation of service vehicles from customer car traffic.* For service vehicles (trucks, trailers, and garbage- and trash-collecting vehicles), separate roads, branching off from the general road system at points removed as far as possible from the shopping area, should be provided. Ideally—and this can be accomplished in large regional shopping centers—separate entrances and exits to the public road system should be planned. If this arrangement is not feasible, the service roads should branch off from the perimeter circulatory road or, in smaller centers, from general entrance and exit roads before such roads take on the characteristics of parking lanes. Under no circumstances should service vehicles cross roads that directly serve parking operations. Public transportation vehicles should be similarly separated from customer car traffic.

CHARACTER OF THE BUILDINGS

The shopping center establishes a new environment resulting from the banding together of individual businesses in cooperative fashion with the aim of creating greater commercial effectiveness through unified endeavor. It is important that the individual characteristics of the participants not be suppressed, but encouraged. It is equally important, however, that a strong common denominator be created to tie the individual enterprises into a homogeneous unit. These dual aims can be achieved by skillful planning and design. Buildings for single tenancy, for example, are planned not only in accordance with the specific requirements of the specific tenant, but also in harmony with the character of the over-all shopping center architecture. Such buildings thus offer a variation of the main theme rather than the introduction of a new one (Fig. 18).

Regimentation is as much to be shunned as anarchy. Complete control of store-front design results in monotony and dullness, and diminishes the enjoyment of window shopping, which thrives on excitement created by ever-changing designs and colors.

REGIONAL SHOPPING CENTERS

Small depth is needed if service facilities are in basements and pedestrian traffic moves only on one side of structure

Greater depth is needed if delivery is at back of store on ground level and storage facilities have to be provided on ground level for each tenant

Greater depth is needed if shopping traffic moves on both sides of individual stores

The cooperative spirit is best expressed if individual design of tenant stores is encouraged within established limits; around these individual design areas there must be a framework of architecturally controlled areas large enough and treated with sufficient forcefulness to hold the varying expressions firmly together (Fig. 19).

PEDESTRIAN AREAS

Open spaces must be more than narrow lanes between long rows of stores. They must be busy and colorful, exciting and stimulating, must make walking enjoyable,

and provide places for rest and relaxation. All the senses should be rewarded. Trees, flowers, fountains, sculpture, and murals, as well as the architecture of freestanding structures, are vital parts of the over-all scheme. Public events such as fashion shows, holiday celebrations, and exhibitions are all parts of the life in these open spaces, as are snack bars, outdoor cafes, and restaurants.

Shopping must thus be understood as more than a utilitarian activity. The environment should be so attractive that customers will enjoy these trips, will stay longer, and return more often. This will result in cash registers ringing more often and recording higher sales.

Stores of varying depth and width can be arranged between multiple-tenant structures by skillful division and orientation of stores

By MURRAY S. COHEN, AIA, Architect

GENERAL

People love to look, window-shop, and buy. Shopping as an experience should provide fun, which in turn provides profits. A successful store or shop is one that is designed to merchandise in addition to looking good. A store can be divided into two principal parts: the *exterior*, which gives identification, encompasses the storefront, show windows, and displays, and the *interior*, where the promise of the storefront display is delivered. Briefly stated, the storefront initiates the sale, and the interior consummates it.

The storefront and the design of the facade must be attractive in order to catch the shoppers' attention and to draw the customers in from the street or from the mall in shopping centers. Graphic identification, with bold color, lighting, lettering, and logos, and attractive display of merchandise are the initial steps.

In enclosed malls, the glass-enclosed show windows are often eliminated or minimized. The "show window" displays are set up in a large vestibule, perhaps elevated or on portable platforms, and become part of the interior. Hence the demarcation between the exterior and the interior is not physical, rather the two are integrated, and it is difficult to define where one ends and the other begins. This is particularly true in enclosed shopping malls. The open or no front generally promotes more impulse buying; department stores will often make their entrances an extension of the mall so that the shopper will be easily enticed into the store. When doors are used, either on the street or on the mall, they should be well marked and easy to find. Entrance to the interior should be easy, related to interior traffic flow and layout, and should be accessible to vertical transportation, if any.

PRINCIPLES OF RETAIL SHOP DESIGN

In order to design satisfactory shops, the first requirement is an understanding of those portions of current merchandising theories which affect the design problem. Briefly, "merchandising psychology" consists of, first, arousing interest; second, satisfying it.

With staple goods the first phase is almost automatic. When nonstaples, accessories, or specialties other than "demand" goods are to be sold, methods of arousing interest may become more complex.

The second phase—the actual sale—involves factors of convenience which are desirable in order to make buying easy, to satisfy customers completely, and to achieve economy of space and time for the store management.

Both phases affect the design of retail shops, and are closely interrelated. In some cases the planning problems involved cannot be segregated. A more detailed listing of steps in the merchandising process, as they affect shop design, follows:

Attracting Customers

This can be accomplished by means of advertising, prices, show-window displays, or new

or remodeled quarters, which occupies much of a merchant's efforts. Of these, storefronts and display windows are important to the store designer.

Inducing Entrance

Show windows, in addition to attracting passersby, should induce them to enter the store. Show windows may be opened up to display the shop's interior; or closed in, to give privacy to customers within. Door locations require study in relation to pedestrian traffic flow, grades of sidewalks and store floors, and interior layout of the shop. In colder climates drafts and outdoor temperature changes can be controlled at the door.

Organizing Store Spaces

Organizing store spaces, and consequently the merchandise to be sold, into departments, enables customers to find objects easily, and permits storekeepers to keep close check on profits or losses from various types of goods. Store lighting and "dressing" are simplified. Even small shops benefit from a measure of departmentalization; in large shops, the practice becomes essential as methods of training salespeople, of handling, controlling, and wrapping stock become more complex.

Interior Displays

Interior displays require particular attention in specialty shops. Types range from displays of staple goods which assist customers in selection, to displays of accessories which the sale of staples may suggest to the customer. Problems of arrangement with regard to merchandise, departments, and routes of customers' approach are involved.

Relief from the repeated impact of merchandise sales efforts and displays is necessary in most shops. Experienced salespeople can tell at a glance the customer who is satiated with shopping and too bewildered to buy. After

he has been refreshed by a brief rest, the customer's interest can be recaptured quickly. Such relaxation may be mental or physical, or both.

Conveniences

Conveniences intended primarily for the customers' benefit, while not strictly allied to the problems of attracting trade or selling goods, are necessary to some types of shops. A florist, for instance, provides a card-writing desk or counter in his shop. In other shop types, particularly those whose prices are above the average, such extra provisions are often highly desirable. Conveniences of this kind include: telephone booths, drinking fountains, lavatories or powder rooms, desks for writing cards or checks, stools or chairs at counters or in special sales rooms, and vanity tables or triplicate mirrors for certain types of apparel fitting rooms.

In regard to finishes and equipment, the idea may be extended to include: floor surfacing for comfort; acoustic treatment of ceilings and possibly walls; illumination of pleasant, sometimes special, quality; and air conditioning. All these have been found profitable investments in various cases. Their necessity or desirability depends to an extent on the type of shop, its location, or the climate of the locality.

INTERIORS

The successful retail shop is an efficient selling machine or sales factory. In addition to servicing the customers, the employees have to be considered so they can give better service to the customer.

Merchandise and space must be organized to help the customer in making a selection and to help the sales person in selling. Easy circulation and exposing the customer to the maximum amount of merchandise are part of good design. Avoid monotony in circulation and dis-

Fig. 1 Principles of shop design. Merchandise is located according to classification: staple goods are unobtrusively yet accessibly placed; luxury items are spotted where the prospective customer cannot help but be attracted to them. White counter areas are allocated to services: cashier, wrapper, information, etc.

play of merchandise. Where possible, do not hesitate to be bold or even shocking. This stimulates the customer and his urge to buy.

The location and design of the cashier and wrapping unit are important and provide for several persons to be serviced. Often this acts as a control center.

Flexibility so that fixtures and departments can be moved or modified is part of present-day merchandising. Fixtures should be minimized and merchandise emphasized. Design and use fixtures so that full attention is thrown on the merchandise. Surveys must be made for each particular type of store, its merchandise, operation, and personnel to determine actual sizes and requirements. Do not design fixtures so that a salesperson has to reach merchandise on too high a shelf or stoop too low.

Determine what customer accessories are required: seating in general, counters, tables, mirrors, telephones, drinking fountains, rest rooms, special lighting, and floor coverings. Accessories will vary, depending on the store's location and the type of customer, as well as the nature of the merchandise.

Location of stock rooms, or of reserves, must be carefully considered so that the salesperson does not have to leave a customer for too long a period.

Fitting and dressing rooms should be located conveniently near the item being sold.

Selling Areas

Departmentalization Benefits to be derived from segregation of merchandise by types have been touched upon previously. All these are factors in decreasing the average time per sale, an important figure in large-store accounting and in small stores with rush periods (Fig. 1).

Within each department, and as a guide when relating departments to each other and to the path of the typical customer through the store, merchandise and services can be analyzed by classification. Most objects can be placed in one of the following classes, relating them to the needs of customers:

Impulse, or luxury, goods are high-profit articles, usually (but not necessarily) high in price.

Convenience items are stocked for the passerby who happens in, but who may return for other purchases if properly impressed. Often these are not in themselves strictly profitable merchandise.

Demand goods are also staples, like conveniences, but are articles which the customer starts out with a definite idea of purchasing. These attract him to the store and he buys them—other goods must be sold to him.

These classifications necessarily overlap; but, in a shop whose type of customer can be forecast, divisions along some such lines are possible. Signs are not always necessary; each department may be designated by display of typical articles as a kind of poster.

Customer Flow The accompanying diagrams based upon analyses of traffic indicate the possibility of organizing departments in relation to the flow of customers through the store.

Interest in articles on display was found to be inversely proportional to the number displayed after a low limit had been reached. A central location in a group seemed to lead to increased interest in a picture. One important conclusion is that what a customer sees is more influenced by the arrangement of the space and the walking habits of customers, than by the intrinsic quality of the objects exhibited. Tendencies to turn to the right, to be attracted by doorways, to choose the wider of

two aisles, and to be fatigued by too much material on display are all of utmost importance to the store planner.

Store services must also be analyzed in relation to customer flow.

Self-Service Operators of large stores have found that self-service speeds up selling. For that reason their stock is easily accessible to the shopper. Often, too, customers insist upon handling merchandise, and are more easily sold when they can get these first-hand impressions. As a result, many stores have abandoned the selling-over-the-counter plan, which decreases free sales space, and rely upon open wall fixtures, wall displays, and display tables whenever possible.

In direct contrast to this type is the exclusive shop which keeps its stock in closed fixtures or in the stockroom, permitting selection of merchandise only by sample displays. Some specialty shops work entirely on this basis.

Shop Sizes These are far from standardized. However, as determined by real estate values, and merchandising, structural, fixture, and aisle space requirements, shops with one customer's aisle only are usually 12 to 15 ft wide by 50 to 60 ft long in large cities; and 15 to 18 ft wide by 60 to 80 ft long in smaller cities. These dimensions apply particularly to shops in 100 percent retail districts.

Heights are more easily determined. Basements 8 to 9 ft high, in the clear, permit economical stock storage. Ground floors are preferably approximately 12 ft high if no mezzanine is included; mezzanines at least 7 ft 6 in. above floor level will accommodate most fixture heights. Height from mezzanine floor to ceiling may be as low as 6 ft 6 in. if used for service space only; 7 ft is the preferred minimum for public use.

Typical Counter and Case Layouts

Center Island Type illustrated, $L = 13$ ft avg. min.; $W = 9$ ft 6 in. to 13 ft. Islands composed of showcases only, $L = 10$ ft min.; $W = 5$ ft 10 in. to 6 ft 3 in. For floor tables, $L = 4$ to 7 ft; $W = 2$ ft 6 in. to 3 ft.

Aisle Widths For clerks, min. = 1 ft 8 in.; desirable, 2 ft to 2 ft 3 in. For main public aisles, min. = 4 ft 6 in.; avg., 5 ft 6 in. to 7 ft; usual max., 11 ft. Secondary public aisles, 3 ft to 3 ft 6 in.

See Figs. 2 and 3.

Displays

The segregation of displays in areas specifically designed for the purpose, and in locations selected with respect to entrances and customer traffic flow, is easily accomplished in departmentalized store planning (Fig. 4).

Display Surfaces Locating display surfaces perpendicular to the line of entrance may result in angular plans, or in the use of screens or free-standing display cases, as indicated in the diagram. Locations for display niches, alcoves, etc., may depend on space requirements of the various shop departments and upon the relationship to customer flow lines.

In a shop, "architecture" is preferably secondary in importance to the merchandise displayed. This does not mean that every inch of space must be crowded with goods "on display," because such practice causes loss of customer interest.

Scale An important factor in display is the relation between the possible viewing distance

and the scale of the merchandise. Thus a stairway side wall or narrow passage is suited for small scale display only. Vistas, on the other hand, and displays opposite doorways, have more carrying power and consequently can be bolder. Vistas, or a sense of perspective, can also be created by lighting emphasis. When a lighted display is placed at the rear wall under a mezzanine space which is slightly darker than the store proper, a spatial relationship is set up which depends more upon the relative intensities of light than upon actual distance. It is possible to dramatize objects on display, to make them stand apart from their neighbors and in this way suggest that they are more desirable. On the other hand, it is not always best to separate costly and inexpensive objects. Low-priced merchandise may often be sold by contrast with high-priced objects, and vice versa. Choice of method depends to an extent on the problem under consideration.

Accessible zones, rather than low or high displays, are particularly valuable in self-service portions of the shop. Just as show-window bulkheads are rising and glass heights decreasing, so the fixtures inside the store are bringing merchandise within reach and concentrating it for emphasis.

Show Windows These are designed primarily with the effect upon potential customers in mind; ease in changing displays is also important. Windows must be "dressed" quickly; if they are hard to work with, they will not be changed as often as merchandising policies indicate to be necessary. Variety and timeliness of displays are considered essential.

The diagrams in Fig. 6 illustrate one set of principles whose use increases the value of displays. The same principles may be applied to horizontal planning; the "shadow-box" type of window, with limited display space, is considered most effective by display designers. In conjunction with these, it should be noted that bulkhead heights tend to increase as the size of objects displayed decreases, to permit more minute examination of merchandise.

Glazing of types which do not interfere with vision will materially increase the show window's value. Patented systems, which eliminate reflections, are available; so are types of glass suited to special conditions, such as heat-resisting glass.

Window backs may be closed or open, depending on the type of shop and the degree of customer privacy desired. When backs are open, confusion of display and shop interior may be avoided by using temporary or permanent screens or panels as backgrounds.

Window dressing may be done in full public view in certain types of shops, as jewelry or gift shops. In other cases, venetian blinds or other types of glass curtains may be required. Apparent size of glass area may be changed to accommodate varying displays by using variable valances and side-pieces.

Storage space is required for display accessories, forms, blocks, platforms, panel backgrounds, and seasonal changes of floor pads or carpets.

Ease of window dressing may be aided in several ways. Access panels should be large enough for easy passage for men and materials. Access passages, segregated from the shop's interior, may be provided. Dummy windows may be provided, sometimes on rolling platforms.

Show-Window Lighting In many stores other than specialty shops, light intensities have been increased far above requirements for ordinary vision, in an effort to overcome reflections.

BY ANGULAR PLANNING

NO SCALE

Fig. 4

This has also been considered a means of competing with adjacent store windows.

Shop Entrances Show windows cannot stop at merely attracting and stopping passersby. Patrons must be induced to enter the shop.

Steps are considered inadvisable. When a change in grade is necessary, and it is too great for a ramp, the steps may be in the store, well lighted.

It is necessary to provide some form of protection from drafts at entrances, particularly in cold climates. In air-conditioned stores, in order to maintain the conditioning system's efficiency at a maximum, a seal between indoor and outdoor air may be needed.

Vestibules offer such protection, and may be made removable in summer months. Revolving doors are often essential where wind pressures are high, when volume of traffic is great, or when air conditioning is used.

Work Areas

Wrapping and Cash Register Counter Locations for these require study. The type of shop will determine whether these services should be out in the open or concealed, near or remote from the door; positioned to permit a salesclerk to make change while facing the doorway, or, as some managers prefer, to do nothing else when ringing up sales. In other shops, a cashier is considered to provide better control and efficiency. Some shops have a separate

room or curtained alcove for wrapping and cashier space, or a basement or mezzanine served by dumbwaiter and pneumatic tube (Fig. 6).

A cash register and wrapping counter in an alcove near the door, which permits the clerk to face the shop and doorway, is desirable in small shops where business is hurried, or where for long periods one clerk must sell, order, wrap, ring up sales, make change, and watch the shop. A store with a narrow entrance might better have these services remote to avoid crowding at the doorway. The separate wrapping room, basement, or other space is used in stores with a more leisurely trade, or when, as in many gift shops, goods are fragile and rarely carried out by the customer. It is less confusing and less "commercial" in appearance for the shop as a whole to have this service outside of the selling space. However, such planning increases customers' waiting time.

Proper location of the cash register for safety may also be dependent upon a wide variety of factors such as number of salespeople, type of show-window back (open or closed ones which conceal the shop from the sidewalk), and type of neighborhood (busy or quiet).

There is in the more exclusive small shops a tendency away from the use of cash registers. Some merchants consider them too commercial in appearance and provide a simple cash drawer, sometimes without a bell alarm. This naturally is a case of individual preference and reliability of personnel.

Waste Basket Space for waste baskets should be provided in each department. This can be arranged under a counter or in a back fixture near the wrapper by omitting the base. When in a counter with recessed toe-space at the front, such waste basket space will have a small ledge—the top of the toe space—which should be continuously braced.

Offices Mezzanine space overlooking the store is the most popular location for management offices. Venetian blinds are often used as a screen; semi-obscure glass may be used; transparent mirrors can also be used, but the space they conceal must be darker than the store side. A practical way of doing this on a mezzanine used for working offices is to run the corridor along the front of the mezzanine, separating the mirror-screen from the offices.

WOMEN'S WEAR SPECIALTY SHOP

This type of store is usually one of two types:

1. A chain-store operation, usually selling at lower prices with greater quantities, which requires mass display and mass selling, sometimes a multiple-floor operation. There is usually more self-service and less contact and selling required by the salesperson. All merchandise is up forward in selling areas.

2. A medium- and higher-price operation, usually a small store, most often owner-operated. There is more personal selling and closer contact between salesperson and customer. The smaller stylish store does not necessarily

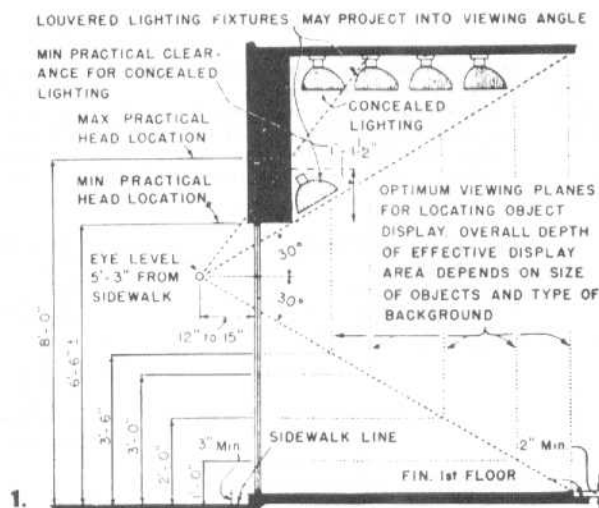

Fig. 5 Determining optimum show-window depths. Within a 60° cone, the average human eye sees comfortably, without appreciable physical effort. Optimum viewing planes are those in which objects on display can be seen in their entirety without causing the eye to encompass arcs greater than 60°. Diagram 1 illustrates a graphic method of determining optimum viewing planes for given bulkhead heights. Diagram 2 shows the application of these principles to second-floor windows; sight lines are limited by practicable window dimensions. Diagram 3 extends basic principles to include both basement and first-floor levels, seen through one window.

The exterior of the lower-price store, like the interior, will have large displays, hence large show windows with low bulkheads. The vestibule, or distance from the building line to the entrance doors, is usually greater than for the

The interior for both types of stores is departmentalized, and the store is divided into related departments. The front part of the store will have the impulse items such as bags,

gloves, hosiery, lingerie, sweaters, and costume jewelry, with the cashier and wrapping counter. The rear will have the demand merchandise such as dresses, coats, suits, robes, and sportswear. The cases for this merchandise are often set away from the walls to provide space behind for the fitting rooms, stock, alterations, and work room.

RETAIL SHOPS

Women's Wear

Good general lighting for main areas, lighting pattern in areas architecturally separated, can vary from the general light pattern. Adjustable spotlights for changing displays and special lighting should be provided at fitting mirrors or over counters. Carpet should be used throughout except in stock or work rooms.

In shops for women's clothing and haberdashery, the turnover of stock must be rapid, as styles quickly become obsolete. Most articles, other than accessories which are easily damaged or lost, are currently at least partly sold on a self-service basis.

Nonselling Areas

A workroom for marking merchandise, making small repairs, and preparing articles for display is needed. A hanging pole, some shelving, and space for ironing board use are required. The minimum area can be 4 by 6 ft. Larger shops may have a complete alteration department (Fig. 10).

Sales and Display Areas

Departmentalizing is necessary, due to the varied kinds of merchandise sold. Novelty jewelry, stockings, gloves, and sweaters are all placed near the store entrance; coats, dresses, and hats are farther back in the shop. Sweaters and knitted suits are kept on shelving, usually glass, because hanging stretches them out of shape. The hat department requires some separation from the rest of the shop.

It has been found important in all apparel shops to have several display niches, really interior show windows with or without glass, which should be lighted, for the display of ensembles and related accessories. This is almost essential to suggest associated articles.

Triple mirrors are needed where clothing is to be tried on. Double mirrors, angled to one another, may prove as satisfactory as triple mirrors. Hand and table, wall or counter mirrors are needed in millinery departments (Figs. 11 and 12).

Mechanical Systems Lighting of triple and other mirrors and fitting rooms is extremely important. Strong direct overhead lights are to be avoided because they cast unflattering shadows. Well-diffused indirect light with direct side light has been found fairly satisfactory. Special "daylight" fixtures and lamps are helpful in color matching.

Fig. 11 Fitting rooms; 3 by 4 ft is minimum size.

Fig. 12 Triple mirrors.

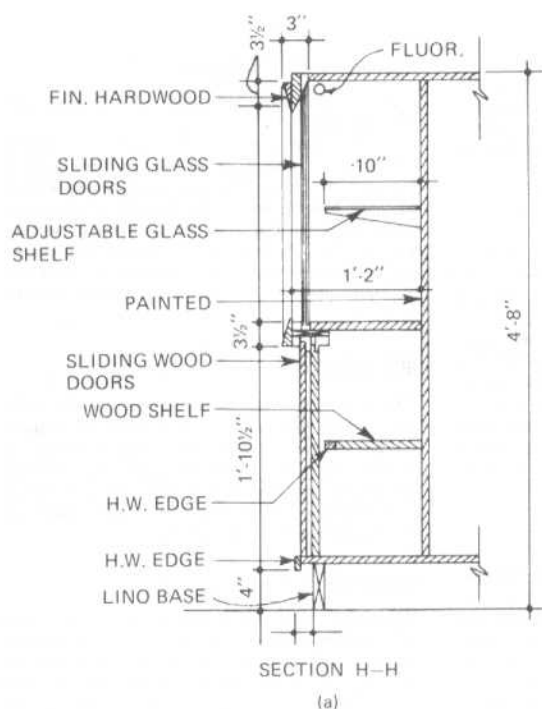

Fig. 13 Island display cases. (a) Boy's furnishings accessories. (b) Men's furnishings stock shelving. (c) Front view.

MEN'S WEAR

Counters and clerks' aisles are seldom, if ever, included in clothing sales space, but are ordinarily required in combination with wall cases for haberdashery and accessories. One or more fitting rooms are necessary in clothing departments; a small fitting platform, one step high and approximately 4 ft by 4 ft, is sometimes needed. Chairs and smoking stands are standard equipment. "Daylight" lighting fixtures aid in matching or determining colors.

Nonselling Areas

Stock rooms, with space for about 20 percent of the store's total stock, are usually sufficient for peak-load seasons. If alterations to clothing are made on the premises, a tailor shop, with water and electrical connections for pressing and sewing machines, is required. Wrapping counters for clothing departments are often located in workrooms; for haberdashery, wrapping counters are usually combined with cashier's space, which is located conveniently to both departments (Figs. 13 to 15).

RETAIL SHOPS

Men's Wear; Book; Gift

Fig. 14 Men's wear cases.

BOOKSHOPS

Each customer in a bookshop requires privacy, direct access to the books displayed, and sufficient light for comfortable vision while reading. Bookbuying customers like to browse, and nothing is less attractive to them than crowded circulation.

Sales and Display Spaces

The first requirement is a plan which by means of low book shelving provides alcoves or selling recesses into which customers can be drawn out of the main circulation. Such an arrangement increases lineal feet of shelving.

The second important step is to assure fairly high intensities of lighting, not only on shelves and displays, but everywhere to permit book reading without discomfort at any place in the shop.

The third step is the design of store fixtures which sell books.

Design of Store Fixtures

This requires considerable study. The front cover of a book is three or four times as wide as the backstrip. Consequently, display which features this maximum dimension secures the maximum display value of jacket design and title lettering. For this reason there is a trend,

particularly noticeable in chain bookshops, to use the most accessible area of the fixture, at about hand height, for front-cover display. There are some disadvantages to this practice, including loss of stock space and untidiness resulting from piling books too high on counters. This latter practice also makes access to lower display shelves difficult. Some otherwise waste space behind vertical "front-cover" displays may be used for stock. Use of sloping counters, with rims high enough to retain only one layer of books, will prevent the second practice.

All shelving should be within normal reaching distance; the maximum height to which the average adult can reach is from 6 ft 3 in. to 6 ft 6 in. Display and stock tables may be introduced in wider alcoves. Aisles not less than 3 ft wide are preferred; main circulation aisles are not usually greater in width than 6 ft or 6 ft 6 in., for large shops.

Nonselling Areas

These consist of wrapping and cash register space, small office and employees' lavatory, and necessary room for mechanical system equipment. Location of all of these varies with each job. In small, "one-man" shops, wrapping, cash register, and office space may be combined and located near the entrance for easy supervision. In no case should these areas obtrude upon customer space.

Lighting and Air Conditioning

Lighting is preferably high in intensity and without glare.

Direct lighting concentrated on the fixtures' selling zone—the area of the counter and of the two or three shelves immediately above counter height—has been found satisfactory. Light sources are best concealed. Complete air conditioning will aid in preserving stock, and is often necessary to increase the comfort of customers in the rather confined alcove spaces.

GIFT SHOPS

The problem in designing gift shops is complicated by the variety and number of objects which must be displayed. Merchandise is seldom bought without seeing and handling either the actual object or a sample. Cleaning and arranging such a varied, fragile stock is a serious maintenance problem.

Selling and Interior Display Areas

Departmentalizing the stock is valuable but difficult to achieve, and is ordinarily accomplished differently for each job, depending on the general type of merchandise. Objects may be arranged according to material, texture, and color; or according to function; or in mixed groupings coordinated according to probable

RETAIL SHOPS

Gift; Jewelry

use. Both classified and mixed groupings are considered essential. Times and seasons for various types of merchandise must be considered and display space provided to accommodate these changes in positions and importance relative to the regular stock.

Shelving is required for all small objects, such as glassware, pottery, silver, etc. Sizes range from 8 to 12 and even 20 in. in width; below counter height, shelf or stock space is often enclosed to protect objects which might be damaged by dust. Sales counters are usually eliminated; although, again, for small, perishable articles, glass show cases may be advisable. Closed displays with concealed soffit lighting have been found valuable for such objects of special value or fragility, articles which deteriorate if left in the open (leather, silver, plaster, unglazed terra cotta). Sale of gift merchandise implies the writing of cards and notes for enclosure, and of checks. One or more desks should be provided for customers for these purposes. It has been suggested that space should be provided for telephone books for addresses.

Show Windows

Most gift shop window backs are open, or partially so, in order to give views through into the shop. Lighted interior displays visible through open backs often attract customers. Flexibility is sometimes demanded; that is, a window with a back which may be open or

closed at will. Lighted recessed shelving in the window side or backs, or on adjustable brackets, exploits varied display levels.

Nonselling Areas

Stock rooms require a range of sizes of shelving, from 8 to 12 or 20 in. wide, as well as closed cupboards for objects which might be damaged by dust.

The receiving and packing room will have to handle large quantities of inflammable packing material.

A wrapping table, 3 ft 6 in. by 5 ft, with two paper rolls, 18, 24 to 30 in. long is usually sufficient. Weighing scales are required.

JEWELRY SHOPS

Jewelry stores range from the small shop which sells fine, expensive, and exclusive items to the commercial credit store which displays and sells in volume, and then to the costume jewelry shop. Jewelry, at all prices, is an impulse item and so needs good visual appeal.

The better jewelry store is a small store with a small front and may be the open or see-through type. Displays are on an individual basis, uncluttered, very well illuminated, and up high for easy, close examination. This store is never self-service; it requires individual leisurely attention to the customer. Displays and counters are individual units. Small tables, sometimes combined with a small display or

showcase (Fig. 16), are for the customer and sales person to sit down during the transaction.

Very exclusive shops will have private salesrooms for special customers. Sometimes these are glass enclosed and have drapes that are drawn when the room is used and complete privacy required.

Wall displays are shallow, individual, glass-enclosed, and intensely illuminated. The repair department should be located at the rear of the store and completely visible to the customer through glass.

A larger store may have several departments such as silverware, gifts, crystal, glass, and china which may be displayed on and sold from open shelves against the walls, with no counters, or from island counter units.

All jewelry items are removed from the show windows, displays, and cases and put into the vault when the store is closed. Display cases have small removable trays that are transferred with the jewelry into a special section of the vault made to receive these trays. Protection is important and must be considered in the early part of the design with the agency that will provide the service. Lighting is critical, primarily incandescent, with blue fluorescent to offset the yellow in the incandescent.

Provide sufficient counter mirrors and occasional full-length mirrors.

In the better store cash is generally handled from a cash drawer at the wrapping counter located in the rear or in the office. The entire store must be inconspicuously visible from the

Fig. 15 Umbrella display.

RETAIL SHOPS

Jewelry

Fig. 16 Jewelry.

stock room or office. This may be done with the use of one-way mirrors.

The credit jewelry store, or the popular price store, caters to volume in both customers and merchandise. Counters are of the stand-up type; not individual (Fig. 17). Two, three, or more are combined into a single long unit. Displays on the interior and the show windows will have a mass display of items. The cashier and wrapping desk are located at the front of the store for better control.

Jewelry is sold by persons trained to give individual attention to each customer. Patrons are given little opportunity to handle merchandise except in the presence of a salesperson. Valuable stock is ordinarily locked in a vault each night, and the entire store must be "dressed" each morning.

Sales and Display Areas

These are divided into a general salesroom for ordinary customers, and one or more private rooms for customers who wish to buy expensive items, usually precious stones.

No counters, in the ordinary sense, are provided; it has been found preferable to have nothing between customer and salesman. Both sit at tables, 2 ft by 3 ft in size, which are spaced at 9 to 10 ft intervals for privacy. A few display cases are used, and stock drawers to hold jewelry trays. Display tables for stationery and watches are sometimes fitted with display drawers, the full size of the table, and visible through a glass top. Wall cases are often recessed in salesroom walls.

Private sales cubicles may be from 6 to 7 ft by 8 to 10 ft. Furniture should include 3 or 4 chairs and a sales table.

Show Windows

They usually have high bulkheads, are small in size, and have opaque backs. Displays are usually limited, and small in scale. Glazing should interfere with vision as little as possible.

Fig. 17 Costume jewelry.

RETAIL SHOPS

Jewelry; Barber; Tailor and Cleaner

Nonselling Areas

Protection of stock is important, although there are few deleterious influences against which jewelry must be protected. Pearls and ivory will not stand heat. Silver will tarnish; watches and clocks must be oiled and regulated. A jewelry polishing shop may be needed in a room adjacent to the general offices. This is about 8 by 8 ft with benches, shelves, sink, and electrical tools.

Protection against theft is provided ordinarily by keeping stock in a vault at night, and by installing alarm systems at all windows and doors. Where available, various private, police, or similar protective agency systems are usually interconnected.

Conveniences installed for customers' comfort include private telephone booths, drinking fountains, and a lavatory, as well as vanity tables.

Offices may include spaces for manager, clerical department, telephone switchboard, and registry (accurate records of purchases are usually required by law). Offices are often in mezzanines. Shipping departments may be in basements or first floors.

BARBER SHOP

The typical five-chair barber shop can be accommodated in a store 14 by 42 ft. in size. A shop for a small community ordinarily has a single shampoo basin; if individual basins are required at all barber chairs, space requirements have to be slightly increased (Fig. 18).

FLORIST SHOPS

In flower shops, selling and display areas are combined, and temperatures must be kept low to prevent loss of stock. Show windows are almost always completely open, to display the entire shop's interior.

Selling and Interior Display

Refrigerated cases inside the store are usually raised off the floor on a bulkhead for ease in reaching in and in cleaning. Maximum depth for reach-in cases is four feet. Sliding glass doors are usually standard.

Shelving and racks are required for vases

and pottery. Shelf dimensions depend on the stock to be carried. Desk space for several persons, for writing gift cards, is another requirement. Desks may be of the stand-up type, possibly attached to columns.

Finishes Floors both in public spaces and in refrigerated cases, must be impervious to water; linoleum, tile, glass brick, and similar materials have proved satisfactory. Walls are often mirrored, since repeated reflections are found to be helpful to the sale of stock.

Mechanical systems Store temperatures are held down to approximately 50°F for best conditions. Refrigerated cases are kept at 42 to 50°F for roses and some other species of flowers.

Cooling coils are usually placed in the tops of cases, with compressors in basement spaces.

Nonselling Areas

Workrooms are required for preparing special displays, floral pieces, and for storing watering cans, ribbon, twine, paper, boxes, and additional pottery. Workroom sizes are not standardized. A sink with a high cold water tap, or hose, is required for filling watering cans.

Ribbon is stocked in rolls from ¼ to 10 in. wide. Boxes are stacked on tables or shelves for each day's trade; 150 boxes is an average for moderately large shops. Table may be 4 by 8 ft; box shelves may be 1 to 3 ft deep.

Fig. 22 Drugstore.

DRUGSTORES

Today's drugstore is no longer the small neighborhood pharmacy or "wet" store that included a soda fountain with tables. It is now either a small "dry" store, primarily handling prescriptions, sundries, and cosmetics, or the large variety type of store, very often part of a chain operation with certain departments leased out. In addition to the departments already mentioned for the small store, it may have a complete luncheonette and departments for tobacco, film, greeting cards, books, and certain household items typical of the variety store. The larger store very often is part of a shopping center complex.

Storefronts are simple, generally the open or see-through type, with shallow display windows with high platforms.

Interior must be well organized and grouped or departmentalized. The prescription department usually is in the rear of the store, with a small seating or waiting area. This is similar to typical department store selling, which forces the prescription customer through the entire store and past the impulse items. Very often the tobacco section will also be located in the rear, for the same reason, though some operations prefer to handle tobacco at the cashier along with film. The luncheonette normally is at the front, as is the cosmetics department, with drugs and sundries centered, and the book department and telephones again favored in the rear.

Large operations will have several controlled check-out counters at the front, with separate cash registers at the pharmacy and luncheonette.

Fig. 23 Pharmacy area of drugstore.

RETAIL SHOPS

Drug; Liquor

The only departments requiring or using counter service are prescriptions, cosmetics, tobacco, film, and radios. All other selling is from open displays, gondolas, and wall shelving, usually continuous for flexibility identical to that used for supermarkets and with a curtain wall and continuous light cornice at the top of the shelving.

If the prescription and pharmacy work area is elevated one or two steps above the main floor, it provides a better view and control of the entire store. The layout and operation of the prescription department varies with the individual pharmacist. The work area is divided into a wet and dry area with a worktable, stainless-steel sink with hot and cold water, and a refrigerator. In addition to bottle and container storage, generally under the workbench, space is required for prescription files, current and past. Keeping good records is mandatory by law (Fig. 23).

By A. PETER FLORIO Designer-Consultant

LIQUOR STORES

The liquor store will consist of many ideas such as:

1. Zoned and cold wall refrigeration
 2. Perpetual inventory systems
 3. Refrigerated gondolas
 4. Electronic air filter system to remove dust and dirt from sales area
 5. Automatic check-out systems
 6. End of pilferage
 7. New approaches to exterior store design
- New product ideas such as:
1. Frozen and refrigerated cordials, liqueurs
 2. Complete lines of powdered cocktails, mixed drinks

The rapidly growing "spendable income" of the American public is the single largest factor, for the perpetual stream of new products and new packaging that enters the retail liquor industry constantly is slowly bringing about new ideas in product development and product presentation which, in turn, create new demands and new requirements for equipment manufacturers and store designers.

All these new items create new problems of merchandising techniques. In conjunction with these new products, the percentage of women customers is ever increasing. Within the next 10 years, women will outnumber men customers, as liquor in one form or another is becoming more and more of a staple item in the average American home.

Women shoppers are more demanding, more critical, and more susceptible to a properly designed merchandising layout in an attractive well-lighted store, and they are bigger impulse item buyers than men. (And they also control most of the family money.)

The selling area will either be covered with carpeting, which will be specially designed with a foam backing that will eliminate a large percentage of bottle breakage in the sales area, or floor tile that will never need polishing.

The merchandising layout will be completely different than we know today, with the use of

zoned and cold wall refrigeration. Appearance-wise, the shelving will basically look as it does presently, but each shelf will have temperature control as required to hold each category of merchandise at a correct holding temperature. Walk-in coolers will be eliminated as a means of refrigeration.

One example of the usage of the cold-wall method is as follows: 99 percent of every liquor store in the United States today has a partition wall separating the back room from the sales area, and in almost every case the cooler is either in front of this partition or the partition is built flush with the front of the cooler, with the cold-wall idea, when the partition is built. Cold panels will be built right into the wall with up-rights placed every four feet for adjustable shelving. All the can beer and beverages can be merchandised this way, for combination case beer, can beer, and beverage merchandising.

The zoned refrigeration idea will be used so that case beer can be stacked 2 or 3 cases deep and with adjustable shelves for loose merchandise. This method can be applied to any length and width of floor space required. This same idea will be used to encompass the wine wall shelving. The shelf merchandise will maintain a temperature range of 37° to 61° which can be adjusted to hold at a preselected temperature, and percentage of humidity to properly contain the product.

The same method of zoned refrigeration will be used on all gondolas that will be used to merchandise estate and chateau bottling of wine; cordials and liqueurs (that can be held in a frozen or refrigerated state, thereby offering more true flavor and taste than is now possible); gourmet foods and can beer.

It will have an electronic pilferage detection system such as the sensormatic detection system which uses a sensitized dot in the price tag or sticker. It is almost impossible to find the dot without special equipment.

If the package or article is properly checked out through a cashier, the dot is desensitized by equipment under the counter. If the shoplifter conceals the package or article and gets by the cashier, the dot continues to give off electronic signals that are picked up by a sensitive detector at the exit, notifying security officers that a theft is taking place.

Location Analysis

Downtown City Location

- * Advantages Pedestrian traffic is principal advantage. Also availability of business market.
- * Disadvantages High rentals, competition, lack of parking facilities.

Suburban

- * Advantages Upper income customers. Considerable home entertainment. Good gift market.
- * Disadvantages Lack of street traffic. High delivery costs.

Industrial

- * Advantages Excellent customer pool. Both business and labor.
- * Disadvantages Peak selling periods. Pay days, after working hours. Need for lots of small sizes.

Residential

- * Advantages Regular customers. Opportunity for promotion.
- * Disadvantages Customers in mixed income groups. Therefore, need to maintain variety of services.

Shopping Center

- * Advantages Heavy traffic locations. Good parking facilities.
- * Disadvantages Mostly female traffic. Distraction of other types of stores.

Highway Location

- * Advantages Customer convenience. Heavy automobile traffic.
 - * Disadvantages Not easy to "stop" customers. Need for extensive parking facilities.
- As mentioned above, there are opportunities to do business regardless of the location.

Considerations in Liquor Store Design

Among the positive marketing trends that are affecting liquor store design today are the following:

1. The change in buying trends of the consumer public
2. The new drinking sophistication of consumers
3. The emergence of women as liquor store customers
4. The home entertainment boom
5. The constant flow of new brands, new products, new sizes entering the market to meet the new demands of consumers

There are also some negative trends, and stores must be designed to cope with them. They are:

1. The shortage of experienced personnel
2. The high cost of overhead and daily operation
3. Extreme price competition in many sections of the country
4. Pilferage problems in some city areas
5. Regulations, regulations, regulations

In order to properly lay out and design a liquor operation, the following points must be covered in order to achieve the utmost efficiency, flexibility, economy of operation, and profit:

1. Location analysis
2. Structural arrangement
3. Liquor merchandising "problem" areas
4. Product placement
5. Check-out system
6. Traffic control
7. Financing
8. Interior designing
9. Signs and display techniques
10. Refrigeration requirements
11. Electrical requirements
12. Plumbing requirements
13. Air conditioning requirements
14. Heating requirements

See Fig. 24 for some possible layouts.

Interior Design

The basic plan and operation of a liquor store is that of self-service, i.e., open shelving, but with a sufficient number of clerks available to help customers. Women are doing more shopping in liquor stores, particularly the neighborhood store, and are impulse buyers—they need and expect assistance in making selections.

Storefronts are usually the completely open, see-through type without any window backs since many states require the entire interior of the store to be visible from the street. Before starting any plans or sketches, check carefully with local and state liquor authorities about any specific requirements or restrictions because they vary in each area. Merchandise in show windows may be protected by grilles or similar devices. Often only one entrance may be permitted, except when the store is within a shopping center. A separate delivery entrance is desirable, but must be well controlled from the office and, if possible, from

the cashier. Exterior hardware should be omitted on this door.

Show-window platforms should not be too deep, from 4 ft 0 in. to 5 ft 0 in. and should be on the low side, from 6 to 24 in. maximum above the floor. On the exterior, provision must be made for protection when the store is closed by use of an overhead rolling grille or a folding gate. This protection should be over all show windows and the entrance door. The entire premises including all wall and roof openings, such as air intakes and exhausts, must be protected by a well-designed alarm system.

The interior will be departmentalized to the extent that hard liquors, wines, and beer are all grouped and displayed differently. Hard liquors are displayed and sold from shelving not unlike that of a supermarket or super-drugstore, including the typical price or label holder on the shelf edge, and are well illuminated from a light cone at the top of the shelving.

Domestic, inexpensive wines may be displayed and sold from shelving similar to that for hard liquor. Generally wines are stored lying down as in a wine rack except that several bottles would be grouped in one opening and directly under or over the opening would be an upright bottle carefully displayed to give good visibility for reading the label. Being able to read the label on a wine bottle is a must for the customer. Another method is to have sloping shelves with the angle changing to give a better view of the label. Again, all shelving is to be well illuminated. An illuminated wine chiller, with displays, is a must since many wines must be served chilled and a good, steady customer can be developed if he or she knows that a chilled wine can be picked up for immediate use. Pull-out shelves, which hold several bottles, are also handy so a customer may accumulate a selection or await a decision on final selection.

Beer and mixers should be located at the rear and to the side and, if possible, stored and displayed in reach-in refrigeration. Where possible, build these accommodations into the wall. Loading or refilling from the rear is highly desirable for this bulky merchandise.

A gift, or specialty, section and impulse items should be adjacent to or part of the cashier or service counter. Other impulse items, such as gourmet foods, bar accessories, and giftware should be located so that they are easily visible from the exterior.

The cashier, or service counter, is generally located toward the rear of the store, except for very large operations where check-out counters and service carts, as in supermarkets, are sometimes used. When in the rear, the counter should be large enough to accommodate at least two customers at the same time. Discuss with the operator of the store the special requirements for the working side of the counter: the various sizes of bags, wrapping materials, receiving compartments for inventory tags, handling of cash, and cash register security. An office working area is required. If possible, locate it so that from it deliveries can be controlled and a view of the cashier and of the entire store is possible. The entrance door must be equipped to announce the entering or leaving of any person. Liquor stores are prime targets for hold-ups and pilferage.

The center of the floor is generally kept free of fixed fixtures; use portable gondolas or islands. Displays often are made up of merchandise and containers and with material furnished by the suppliers. By keeping the center of the floor flexible, direction and location of displays can be changed.

In addition to the general lighting and lighting over shelving, provide adjustable spotlights

throughout the ceiling area to highlight displays and accent downlights over the cashier.

For floor covering, carpet is preferred in the selling areas, or perhaps wood, and hard floor covering for the storage areas.

If storage is on a level above or below the selling floor, a belt conveyor should be installed. To expedite the handling of the heavy merchandise, portable roller conveyors should be used where there are long stock aisles.

By MURRAY S. COHEN, AIA, Architect

Different requirements and customer demands have generally required separate stores for men, women, and children. A shoe store is a volume trade operation and is highly competitive.

The storefront is the see-through type, with a large enclosed show window for display of the maximum number of shoes. Average depth of the show window is from 4 ft 6 in. to 5 ft 0 in. with platforms 2 ft 0 in. above the floor. Dust on shoes shows up very quickly, downgrading the merchandise, thus show windows should be enclosed and have tight sliding or hinged access doors. A ceiling display grid facilitates the handling of suspended items. In show windows, lighting must be predominantly incandescent; fluorescent lighting is used only to provide general illumination. Provide an exhaust to reduce the heat buildup from the lights. Floors will sometimes have removable plywood panels to which changeable materials are fastened by the window trimmer.

The interior of this type of store must be arranged to accommodate the maximum num-

ber of seats allowing efficient circulation for the salesmen's traffic route from stock to customer and not crowding the fitting spaces in front of customer's chairs. Chairs must be comfortable and have arms to provide separation between customers. Provide plenty of fixed or portable shoe-level fitting mirrors as well as occasional full-length mirrors so that customers can get a full view of their entire figure. The shoe shelving generally has some exposed space in the sales area and some concealed in rear or side stock rooms or areas. Exposed shelving in sales areas should not be higher than can be reached without a step stool; concealed or stock-room shelving can extend up to 10 ft 0 in. Where the height is available, two levels, like library stacks, can be used. A cellar storeroom is required for reserves. (See Figs. 25 to 27.)

Cashier counter should be centrally located for good control and accessibility. The hose bar, accessories, and impulse items are generally located near or adjacent to the cashier.

If possible, arrange for rear delivery of merchandise. An employee toilet, a combination

workbench for minor repairs, and a desk should be provided in the stock room, with quick access to sales room. In certain men's stores selling a better or higher-priced shoe there will be a shoeshine stand serviced by the porter or handyman.

Floors in the selling area must be carpeted. In enclosed shopping malls the carpet is often extended out into the vestibule. Stock rooms can have hard floor covering.

Women's stores usually are more plush, have more of a salon setting, and have less exposed stock in the sales area. Seating is more informal, with love seats and groupings in addition to the individual well-upholstered seat.

Adjacent to or part of the cashier counter there is an extensive hosiery, glove, handbag, and other matching accessories area. A slipper bar is usually a separate section.

In the area or store for children it is highly desirable to have a raised platform, accessible by steps, so that the salesman can better observe the fitting and walking without having to bend or lie down on the floor.

Architecturally, the supermarket is a large-scale emporium of merchandise that doesn't have to shout to be noticed.

Properly situated on its site, the supermarket and any "satellite shops," attached or not (shops which can be entered from the market or from a separate outside entrance) offer a parking ratio of 3.6 sq ft to 1 sq ft of total store area. To obtain the necessary parking area in areas with high land costs, rooftop and basement parking should be considered. The satellite shops such as convenience grocery stores, liquor and drugstores, and a carry-out food shop remain open after the supermarket has closed for the day.

New, free-standing supermarkets average 22,700 sq ft to 31,000 sq ft with 75 to 80 percent of the total store devoted to selling space and the remaining 20 to 25 percent of floor space devoted to service areas such as storage coolers, prepackaging areas, grocery storage, etc. Weekly sales per square foot of selling space vary from \$3.10/sq ft to \$3.75/sq ft (Fig. 1).

About 50 percent of the supermarkets total equipment and fixture investment is in refrigeration equipment—meat, dairy, produce, frozen food, delicatessen, and the storage coolers necessary for each department. The remaining 50 percent is devoted to grocery items—half of which can be nonfood items, such as housewares, soft goods, glassware, health, and beauty aids. The most important square footage is that required by the check-out stands—one for each \$10,000.00 of projected weekly volume plus an additional check-stand for future expansion (this is only a rule of thumb figure and varies with the region of the country and the type of service the market provides the customer). The accompanying plan, adapted to the individual operation requirements, provides a practical guide in the layout of a supermarket.

Assuming proper location of the store on the site, one which makes it most accessible to traffic and parking, the next step would be to decide on the configuration of the store.

Generally, free-standing markets tend to be rectangular in shape, with the narrower portion forming the front-to-rear dimension. Since most often the deliveries are at the rear, the various back room areas (preparation and storage) are located at the rear of the building, leaving the selling space more or less square.

At this point, the method of construction must be considered, particularly the location of any columns. Ideally, these should be kept out of the shopping aisles. Assuming a 7 ft 0 in. aisle between 4 ft 0 in. wide shelving islands, columns spaced in a multiple of 11 ft 0 in. will keep the columns out of the aisles. (Shelving can be cut to fit around columns, and this is preferred to columns in the shopping aisles.)

Although refrigerated fixtures have been and can be located almost anywhere on the sales floor, most often they are located at the walls. They tend to be too large and bulky to be placed in any central location, where they

Fig. 1 Typical free-standing supermarket.

would obstruct the overall view of the store. The refrigerated cases should be placed as near as practicable to their associated work rooms and storage coolers. This also applies to the service departments such as the delicatessen, in-store bakery, and snack bar.

Since all merchandise purchases must be funneled through the check-out counters, they are all located in one location (usually at the front of the store near the exit door).

The size of today's supermarket makes the

use of self-contained refrigerated cases (with a few exceptions) impractical. Therefore, some sort of centralized refrigeration system is employed. (All major refrigeration equipment manufacturers offer a form of centralized refrigeration system and all are basically alike.) Such a system utilizes a bank of compressors and condensers (air- or water-cooled) located in one room with liquid refrigerant running to the individual cases and the heated gas being returned to the condensers.

New bank merchandising systems have been followed by a new bank architecture which no longer needs to follow the old idiom that a bank must retain its aloof dignity. Stability and strength are still to be preserved in the image of the bank, but not to extremes.

Bankers of today have recognized the increased mobility of the nation and the financial needs of the average homeowner, and in combining the two have arrived at a new expression and image for the bank. In projection of future trends, these bankers indicate that the bank of the next decade will blend excitement and attraction with dignity and a modern feeling of solidity. "The banks will be made more inviting through the further use of glass, color, and art; and by offering their services more conveniently; and through increased point of contact at the street and through drive-in facilities."¹

The innovation of the drive-in and walk-up window recognizes today's informal, mobile living and extends the bank's services to make them more attractive and more convenient to the public. Elements that remain open after regular banking hours, such as a meeting room, savings department, and safety deposit vault, serve the needs not only of the customer of the bank but of the general public as well. Flexibility, then, becomes a key word in bank design. The bank of today cannot subsist under the old idea that a bank is for money only, especially when its image is concerned with public activities along with regular banking activities.

The place in which the bank's transactions take place should be attractive, friendly, and unimposing; a minimum obstruction between the customer and the bank's representatives is a must.

However, before any design requirements can be made, the building requirements (both personnel and departmental) must be firmly established and the basic philosophy of banking operations and building design agreed upon.

DESCRIPTION OF SPACES

1. Public spaces

- a. Lobby. This must be easily accessible to the public. It contains reception/information, loan officers, tellers, and check-writing desks.

(1) If located on the lower level or

second floor of a building, escalators are recommended for public conveyance to the lobby.

- (2) Tellers should be located so that they are easily accessible and so that the spaces surrounding them allow easy circulation of the public.
- (3) Loan officers and others who have direct contact with the customer should be readily available.
- (4) Check-writing desks should be placed so as not to block circulation, especially of the lineup space in front of the tellers.
- b. Tellers are usually located at one side of the bank to allow for expansion. This is usually considered to be the most flexible of all schemes.
- c. Officers' platform. This should provide open space for contact officers, cubicles for collection officers, and offices for the installment loan and commercial loan officers. A conference room should be provided in this area unless the need warrants more than one.
- d. Access to the safety deposit vault should be provided for customers. Access to the money vault for tellers should be provided.
2. Operations. This is the department that makes sure the bank is run on a steady, professional basis. It takes care of all the clerical work required to run the bank and keep its records in order.
 - a. Bookkeeping department. This should be in close proximity to tellers, since this is where the tellers receive and give all the information they need.
 - b. Proof department. This is not accessible to the public. It can be separated from the other areas, but should be fairly close to the data processing area.
 - c. Data processing area. Special air conditioning is required here. False floors are recommended to house the electric cables.
 - d. Clerical, mail, and other various minor services as required by the individual situation. The mail room is usually located in close proximity to the proof department.
 - e. Fireproof records vault, to service proof, trust, and bookkeeping departments. This does not have to be adjacent to all three, but access must be provided for all three.

f. Safety deposit vault, fireproof. This provides boxes for the storage and safekeeping of customers' valuables. Coupon booths of minimal size and a conference room large enough to hold 10 to 20 people should be provided.

g. General services. This includes toilets, employees' lounge, snack bar, mechanical equipment, maintenance, and PBX.

h. Drive-in and walk-up tellers. These teller windows are an essential part of a bank. Their design should be carefully considered with regard to flow of traffic and security.

i. Trust department. This is one of the bank's major services to the public. It is here that trusts, probates, accounts, etc., are put in effect and carried out. This area also needs a lawyers' department.

j. Auditorium/meeting room able to seat 200 to 300. This room is mostly used by the public and is often loaned rent free. Rest room facilities, a stage, storage space, and coffee bar should be included. This room should be thought of as an all-purpose room. In addition to serving as a meeting room, it will facilitate the training of bank personnel.

3. Executive suite. Usually includes offices for the senior vice-presidents, board members, and president plus all the personnel they need to continue their business. A conference room and board of directors' meeting room are required.

4. Buildings. It is the duty of this department to maintain the physical building, keep records, and collect rental fees for all spaces in the building owned by the bank.

5. Legal department. This department keeps the bank's legal business in order. A library/conference room is usually included in this area.

6. Data processing. This department helps to facilitate and process the bank's checking, payroll, operations, and other procedures.

7. Mail room. The mail room usually contains the addressograph, microfilm equipment, duplicating machines, and other equipment necessary to run this operation. This area should be located near a service yard or elevator and in conjunction with the printing/purchasing department.

BANK VAULTS

VAULT PLAN - A (8' W x 14' D x 8' H INSIDE)

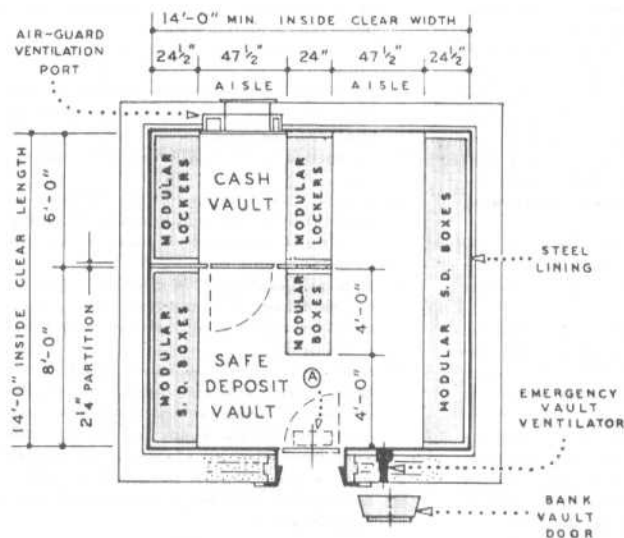

1. 112 sq. ft. inside floor area.
2. 20 lin. ft. for s. d. boxes.
3. 8 lin. ft. for lockers.

VAULT PLAN - C (8' W x 14' D x 8' H INSIDE)

1. 112 sq. ft. inside floor area.
2. 16 lin. ft. for s. d. boxes.
3. 8 lin. ft. for lockers.

Fig. 1 The above plans are recommended for single-aisle vaults up to 14' inside clear widths. Interior vault dimensions should be established in accordance with individual requirements and the emergency vault ventilator should be located through a convenient wall area that is exposed inside the building. Location of the vault alarm control cabinet is designed [sic] by "A" and should be recessed in the vault wall when it interferes with the removal of the bond boxes. When the vault width is 14' or more, refer to double- or multiple-aisle vault plans. (Mosler Safe Co.)

VAULT PLAN - D (14' W x 14' D x 8' H INSIDE)

1. 196 sq. ft. inside floor area.
2. 26 lin. ft. for s. d. boxes.
3. 12 lin. ft. for lockers.

VAULT PLAN - E (14' W x 16' D x 8' H INSIDE)

1. 224 sq. ft. inside floor area.
2. 36 lin. ft. for s. d. boxes.
3. 12 lin. ft. for lockers.

Fig. 2 The above plans are recommended for double-aisle vaults from 14' to 16' inside clear widths. Interior vault dimensions should be established in accordance with individual requirements and the emergency vault ventilator and emergency door should be located through a convenient wall area that is exposed inside the building. Location of the vault alarm control cabinet is designed [sic] by "A." When planning vaults with three or more aisles, refer to the multiple-aisle bank vault plans. (Mosler Safe Co.)

RESTAURANTS AND EATING PLACES

By LENDAL H. KOTSCHIEVAR and MARGARET E. TERRELL

SPACE REQUIREMENTS

Adequacy of space will influence building and operating costs and efficiency. When space is too small, labor time and effort are likely to increase and the volume and quality of output decrease. When it is too large, building and maintenance costs are excessive.

Decisions pertaining to space allowance may be strongly affected by the limitations of investment funds and available space. Ample space is sometimes provided by means of low-cost materials and equipment of such inferior quality that they have short and unsatisfactory service life. In other instances, space is restricted to a point where it prohibits profitable volume or the best utilization of labor. Space allowances in relation to investment should be balanced in terms of (1) proposed permanence of the facility, (2) acuteness of need for the specific operation, (3) essentials for operating efficiency, (4) desirable standards in terms of appearance, sanitation, and good quality of production and service, and (5) immediate and future costs, depreciation, upkeep, and maintenance.

Facts peculiar to the particular establishment should be used as the basis for determining space needs. Requirements will vary for facilities of a given type and volume. Location; type of operation; clientele; frequency of deliveries of supplies; kind of food used, such as fresh, frozen, or canned; and the completeness of processing to be done will cause variation in production and storage requirements. The policies of those in charge will have an influence. Certain general information, such as numbers to be served, turnover, arrival rate, and type of service, will be helpful in deciding dining area needs.

Study is required to clarify immediate and future needs in food production. Choices should be made between meat cutting or portion-ready meats, a baking section or use of commercially baked products, and the use of unprocessed versus processed foods. If enlargement is probable, studies made before the building is planned as to how space may be added and how the initial plan should be designed to minimize ultimate cost, will be helpful.

It is well to block out space allowances according to functions that the facility is to perform. Calculate area requirements in terms of: (1) volume and type of service, (2) amount and size of equipment to be used, (3) number of workers required, (4) space for needed supplies, and (5) suitable traffic area. The dining area location and space allowance are usually determined first, the production areas next in terms of specific relationship to the dining area, and the other sections as required to these. Planners should be careful in accepting general space recommendations. There are many variations.

Dining Area

Space for dining areas is usually based on the number of square feet per person seated times the number of persons seated at one time.

Space Requirements The patron's size and the type and quality of service should be considered. Small children may require only 8 sq ft for a type of service in which an adult would need 12 sq ft for comfort. A banquet seating allowance might be as little as 10 sq ft per seat and that for a deluxe restaurant as much as 20 sq ft. The amount of serving equipment in the dining area and lineup space will influence needs. Lost space must be considered.

The diner's comfort should govern allowance. Crowding is distasteful to many people. It is likely to be tolerated more readily by youngsters than by adults. It is more acceptable in low-cost, quick-service units than in those featuring leisurely dining. Both young and old enjoy having sufficient elbow room and enough space so that dishes of food and beverage are not crowded. Place settings for adults usually allow 24 in. and for children 18 to 20 in. (Table 1).

TABLE 1 Square Feet per Seat Used for Various Types of Food Operations

Type of operation	Square feet per seat
Cafeteria, commercial	16-18
Cafeteria, college and industrial	12-15
Cafeteria, school lunchroom	9-12
College residence, table service	12-15
Counter service	18-20
Table service, hotel, club restaurant	15-18
Table service, minimum eating	11-14
Banquet, minimum	10-11

All of the areas in a dining room used for purposes other than seating are a part of the square footage allowed for seating. This does not include waiting areas, guest facilities, cloakrooms, and other similar areas. Excessive loss or use of space for other than seating in the dining area will, however, increase needs. Structural features of the room should be considered. Width and length of the room, table and chair sizes, and seating arrangements affect capacity.

Service stations may be estimated in the proportion of one small one for every 20 seats or a large central one for every 50 to 60 places. The advisability of having a central serving station will be influenced by the distance of the dining area from the serving area. It is of special value when production and dining are on different floors. Plumbing and wiring and whether supplies are delivered mechanically will influence location of the stations. Small substitutions for silver, dishes, napery, bever-

ages, ice, butter, and condiments may measure 20 to 24 in. square and 36 to 38 in. high. The size of central stations varies from that for a small enclosed room to that of a screened section measuring approximately 8 to 10 ft long by 27 to 30 in. wide by 6 to 7 ft high.

Table size will influence patron comfort and efficient utilization of space. In a cafeteria, for example, where patrons may dine on their trays, it is important that the table be of adequate size to accommodate the number of trays likely to be there. Four trays 14 by 18 in. fit better on a table 48 in. square than on a table 36 or 42 in. square. Small tables, such as 24 or 30 in. square, are economical for seating but are uncomfortable for large people. They are only suitable in crowded areas for fast turnover and light meals. Tables having common width and height allowing them to be fitted together will give flexibility in seating arrangements. These are particularly good for banquet or cocktail-type bench seating along a wall. Tables for booths are difficult for waitresses to serve if they are longer than 4 ft. The width of booths including seats and table is commonly 5½ ft. A lunch counter will have a minimum width of 16 in. and a maximum width of 24 to 30 in. The linear feet are calculated on the basis of 20 to 24 in. per seat. The maximum area best served by one waitress is generally 16 ft of counter. This will give eight to ten seats. U-shaped counters make maximum use of space and reduce travel. Space in depth of 8½ to 11 ft will be required for every linear foot of counter. This will provide 3 to 4 ft of public aisle, 2½ ft for aisle space for employees. A width of 4½ ft is desirable where employees must pass.

Calculate aisle space between tables and chairs to include passage area and that occupied by the person seated at the table. A minimum passage area is 18 in. between chairs and, including chair area, tables should be spaced 4 to 5 ft apart. Aisles on which bus carts or other mobile equipment is to be moved should be sized according to the width of such equipment.

The best utilization of space can often be arrived at through the use of templates or scaled models. Diagonal arrangement of square tables utilizes space better than square arrangement and yields a more trouble-free traffic lane. Lanes that pass between backs of chairs are likely to be blocked when guests arise or are being seated.

Table heights in schools should be chosen for the comfort of children. In units patronized by many grades a compromise height will be needed between the 30 in. normally used for adults and the 24 in. suitable for children, or two sizes may be used in different sections of the room. A table length to seat four, six, or eight is preferable to longer ones.

Number of Persons Allowance The number of persons to be seated at one time is the second point of information needed for calculation of the dining room size. The total number of seats required at one time, multiplied by the space required for each seat, will give the total number of square feet needed in the

RESTAURANTS AND EATING PLACES

dining area. The number of times a seat is occupied during a given period is commonly referred to as "turnover." The turnover per hour, times the number of seats available, gives the total number of patrons who can be served in an hour. If peak loads, or number to be served at one time, are known, the number of seats required can be estimated.

Turnover rates tend to vary, for they are influenced by such factors as the amount of food eaten, the elaborateness of the service, and the diner's time allowance. A breakfast meal of few foods may be eaten more quickly than dinner, and a simple fare faster than a many-course meal. Turnover is quickest in dining rooms where food has been prepared in advance for fast service and where patrons serve themselves and bus their soiled dishes. The turnover time is speeded up 10 percent by patrons removing their soiled dishes so that tables are quickly available for other guests. Deluxe service for leisure dining, involving removal and placement of several courses, takes the longest time. Although specific turnover may vary from 10 minutes to 2 hours, actual eating time is normally 10 to 15 minutes for breakfast, 15 to 20 minutes for lunch, and 30 to 40 minutes for dinner.

The calculation of occupancy of seats in a dining room must take into consideration a certain percentage of vacancy, except where a given number are seated at one time according to assignment. In table-service dining rooms this has been estimated as 20 percent of total capacity, in cafeterias from 12 to 18 percent, and for counter operations 10 to 12 percent. Many factors influence this percentage, such as patrons arriving at different times, irregular rate of turnover, and reluctance to share a table with strangers.

The table sizes used in the dining room will affect occupancy. It is often desirable to provide for groups varying from two to eight, with a predominance in most dining rooms of those for two people. The "deuces" may be of a size and shape that can be put together to form tables for larger groups. In metropolitan areas where many tend to dine alone, wall bench-type seating and tables for two with a center ridge or line denoting space for one have been used successfully. Chairs with a "tablet-arm" that will hold a tray have been used for fast turnover in crowded areas.

The utilization of seating capacity tends to be greater for cafeterias than for table service. The patron may spend 25 to 50 percent of the time while seated at the table waiting for service. The cafeteria diner may begin eating as soon as he is seated. One cafeteria line can serve four to eight patrons per minute depending on (1) the speed of the servers, (2) the elaborateness of food selection, (3) convenience of the layout, and (4) the type of patrons. At these rates, 240 to 480 patrons will need to be seated within an hour. If the turnover rate is two per hour, then from 120 to 240 seats will be used. However, if 15 percent of the total capacity at the peak period remains unfilled, then between 140 and 280 seats will be required. An additional 14 to 28 seats or 10 percent would be needed if the patrons do not bus their soiled dishes.

Patronage estimates for facilities of different types may be guided by the number of persons in residence, enrollments in a school, an industry's payroll, the membership of a club, or the amount of traffic in an office or shopping area. In each case a certain percentage may normally be expected to dine in the facility provided. The percentage will be influenced by such factors as its location in relation to other facilities, the patron's buying power,

the price plan (on the basis of subsidy or profit), patron's mealtime allowance, and convenience of the location.

The patronage estimate for a college cafeteria should take into consideration the number of students who live at home, are members of a live-in group, such as an organized house, and the number of other dining facilities available on or near the campus. A college residence providing table service may have to allow a seating capacity that is 110 percent of occupancy if a policy exists for having "special guest" occasions and seating all at one time.

An industrial lunchroom may serve as few as 25 percent and as many as 90 percent of the payroll. Clues to probable patronage may be drawn from such factors as nearness to other eating facilities, wage rates, type of work, prices to be charged, convenience, quality, and attractiveness. The attitude of management toward the lunchroom may affect patronage also. Pride in providing a good service for the industrial family as opposed to a take-it-or-leave-it attitude tends to win favorable response.

The size of a dining room in a hospital should be determined as to whether it is to be used for employees, patients, or guests, or any combination of these. The type of hospital and the number of ambulatory patients should also be considered. The type of hospital will also influence the number of personnel employed. The ratio of personnel to patients will vary from 1 to 3, depending on how much special care is required or how much teaching and research are done. Good food and reasonable prices will attract a high percentage of those eligible to eat in the facility.

School lunch participation varies 25 to 75 percent and a good percentage for planning is 60 to 75 percent of enrollment. Where prices are low, the food good, meal selections appealing, and the food service carefully integrated with the educational program, the percentage will be high.

Banquet seating requires planning because maximum seating potential means maximum profits. Folding tables 30 in. wide are popular. These are obtained in varying lengths, but 72 and 96 in. are commonly used. The spacing for the legs should be such as to allow for comfortable seating when the tables are joined end to end and place settings are laid on 24-in. centers.

Restaurant operators should consider space in relation to patronage volume essential for a profitable business. Labor, food, and operating costs must be met and a profit realized that covers risk-bearing effort expended and return on investment. Essential income is weighed in the light of probable patronage and probable average check. The number of seats provided in planning must cover this need.

Flexibility in seating capacity is often desirable. People do not like to be crowded nor do they enjoy the lonely experience of being seated in a huge area occupied by only a few. Sparse patronage creates an impression of poor popularity. Separate rooms, folding doors, screens, or other attractive devices can be used to reduce size of an area during slack periods. Sections left open should be those easiest to serve. Balconies, back rooms, or other less desirable space can often be used for overflow numbers that occasionally require service.

A common experience in many dining room operations is the need for more seating at one meal than at others. This may be due either to increased numbers or different turnover rates. A residence cafeteria serving

600 men has an overflow room seating 100, which it uses only at dinner. The night meal is not only larger but the men dine in a more leisurely fashion. The room is available for serving other groups at breakfast and lunch.

Commercial restaurants located in shopping or office areas often have a heavier demand at noon than at the dinner hour. Rooms used for general patronage at noon may be closed at night or provide space for private dinner parties. Entrances to these rooms should not require passage through the main dining room. Convenience for special service is important.

Production Areas

A frequently used rule for allotting space for the kitchen is that it should be one-third to one-half the area of the dining room. It has been found unsatisfactory, however, to go by a set space allowance for this area. Detailed study of space allocations leads to the conclusion that percentages in relation to the dining area are "completely unrealistic and unreliable." An analysis of specific needs is required. Many factors influence space requirements, such as:

1. Type of preparation and service
2. Amount of the total production done in the unit
3. Volume in terms of the number of meals served
4. Variety of foods offered in the menu
5. Elaborateness of preparation and service
6. Amount of individual service given, as in a hospital tray service
7. Seating and service plan, whether on one floor or many

The cost of providing space, equipment, and labor is sufficient to merit careful calculation of the best type of operation before planning. New products on the market, new cooking methods, and new equipment available should be evaluated. The use of preprocessed products in many metropolitan areas has made a pronounced change in the amount of space allotted for bake shop, meat cutting, and vegetable preparation areas. Where portion-cut meats are readily available, it is questionable whether even a large establishment can afford to equip and provide skilled labor for a butcher shop. The use of large quantities of frozen foods affects storage needs. The cost and quality of market products, their availability, and the frequency of deliveries are all to be considered.

Variety in menu selection and elaboration of foods tend to increase space needs in work areas and storage. Small amounts of numerous items do not permit stacking and bulk packaging. Elaboration of food often involves individual portion treatment, with individual casseroles, for example, as compared to bulk steam table pans. A hospital food service requiring many special diets serves as a common example of menu variety and individual portion treatment imposing special space requirements.

The equipment provided will affect the space needs. Garbage and refuse, for example, may require a sizable area for storage awaiting pickup. Disposal units for food garbage, incinerator for burnable refuse, and a crusher for tin cans will greatly reduce the amount to be held. Frequency of garbage collection will minimize the space needs.

Structural features of the building may influence the utilization of space. The shape of the kitchen, location of ventilation and elevator shafts, support columns and partitions should be considered in relation to an efficient layout for work. The location of entrances and

RESTAURANTS AND EATING PLACES

exits for a good flow of traffic, window placement, suitable space, and relationship of sections need consideration. Eliminate partitions whenever possible; this will reduce space needs and also permit easier supervision of production areas.

Kitchens serving a smaller number require a larger square footage per meal than those serving a larger number. The following data used for industrial cafeterias show the rate at which space needs per meal tend to decrease as the number served increases (Table 2).

TABLE 2 Variation in Space Needs in Relation to Numbers Served

Meal load	Square feet per meal	Variation in square feet
100-200	5.00	500-1,000
200-400	4.00	800-1,600
400-800	3.50	1,400-2,800
800-1,300	3.00	2,400-3,900
1,300-2,000	2.50	3,250-5,000
2,000-3,000	2.00	4,000-6,000
3,000-5,000	1.85	5,500-9,250

Planners are often asked to make estimates of space needs before having an opportunity to make policies or detailed plans for operations. Figures that will be found useful in making such estimates are given in Table 3. These figures pertain to average kitchen areas found in different types of food facilities. Their use is to be regarded as tentative and to be measured carefully in terms of specific needs. The square footage given is to be multiplied by the maximum number of meals estimated per hour of service, in order to find the total space requirement.

After production policies have been established, work areas may be blocked out in terms of the equipment needs and the number of workers required to do the work in a section. Linear space, depths, and heights for work centers should be controlled in terms of average human measurements. This will include the reach to and grasp of material or equipment used in working. The length and width of the work table is adjusted in terms of the amount and size of equipment that will rest on it during the progress of work. The linear measurement will vary in terms of the number of workers using it at one time.

The width of the table may be 24 to 30 in. unless dishes or food containers are to rest at the back of the table. Tables 36 in. wide are preferable when the back of the area is used for such storage. Where two workers work opposite each other, a table 42 in. wide may be used. A work area of 4 to 6 lin ft will be within convenient reach of the average person. Tables 8 to 10 ft long are used if two people are working

side by side. A height of 34 in., commonly used as a working height, should be evaluated in terms of specific work done and equipment used.

Aisle space should permit free, easy movement of essential traffic. The minimum width for a lane between equipment where one person works alone is 36 and 42 in. where more than one is employed and where workers must pass each other in the progress of work. Where mobile equipment is used, 48 to 54 in. are recommended. At least 60 in. are needed for main traffic lanes where workers regularly pass each other with mobile equipment. If workers or equipment must stand in the lane while working, appropriate space should be allowed for this. Thought should be given to space for doors opening into an aisle and for handling large pieces of equipment, such as roasting pans, baking sheets, and stock pots.

Main thoroughfares should not pass through work centers. Compactness is essential for step-saving. It is well for the work centers to be in close proximity to main traffic lanes, with easy access to them. It is important both to avoid distraction from outsiders passing through work centers and to conserve space. Work centers at right angles to traffic lanes are efficient (Fig. 1).

The percentage of floor area covered by equipment varies according to production needs and the type of equipment used. A satisfactory layout may claim less than 30 percent of total space for equipment while work areas, traffic lanes, and space around equipment for easy operation and cleaning may require 70 percent or more.

For hospital production and service areas, 20 to 30 sq ft per bed is suggested. The need is reduced as the number of beds increases—approximately 30 sq ft per bed for a 50-bed, and 20 sq ft per bed for a 200-bed hospital. This allowance does not include major storage areas, dining rooms, employee facilities, or floor serving pantries.

Serving Areas

Space allowance of serving areas should be adapted to the needs of the specific facility. The menu, organization of work, and number served will influence size. The type of service will also be influential in dictating space needed.

In cafeterias the counter length should be regulated by the variety and volume. Excess space partially filled is unattractive, but crowding is also undesirable. An estimate that may be used for allotting width is 14 ft. This allows for 4 ft as patron lane space, 1 ft tray slide, 2 ft counter width, 4½ ft for workers, and 2½ ft for back bar. The size of the tray should dictate the width of the tray slide. The average length of counters in college residence halls and hospitals is found to be 30 to 32 ft, while those

in school lunchrooms average around 15 to 20 ft. Some commercial cafeteria counters may be 70 to 80 ft long, but counters over 50 ft long are frequently considered inefficient. Twenty feet is usually thought of as a minimum but, under special conditions and where a limited menu is served, 6 to 8 ft may be sufficient. The trend is toward shorter counters with mobile serving units or dish holders set at right angles to the counter. Smoother service and greater speed are achieved. Counter height may be set at comfortable levels for workers and patrons. Schools may have lower counters so that children may see the food and push their trays along a slide as they are served. For little folk, 28 to 30 in. is desirable, with counters narrow so that servers may reach over to assist a child. A solid tray slide tends to result in fewer accidents than those made of bars or tubing. Plastic trays measuring 9 by 12 in., compartmented, and of pastel colors are popular. Slides for these may be on the servers' side of the counter for ease of service and to eliminate spillage or accidents. The child picks up the completed service at the end of the line.

Some planners use, as a rough guide, one counter or line for every 250 to 300 patrons served, but arrival rate, speed of service, and turnover are more reliable factors to consider in establishing the number of lines required.

Hospital service space will depend upon whether central or floor service is used, trays are set up in serving pantries, and modified diets are set up in line or in a diet kitchen. Space must be allowed for bulk food trucks, tray trucks, small tray carts, or special dispensing units used.

Short-order units where food moves directly from production to the consumer require the least service space. The need for an intermediate station is eliminated. Step-saving compactness saves space. The units requiring the most space are those furnishing elaborate or highly individualized service.

Receiving and Storage Areas

Space allocation for receiving and storage must be based on specific needs. The volume and type of items received and stored should be considered. Although the average operation may find a dock 8 ft deep and 12 ft long sufficient for receiving items, this would not be sufficient for a large one. The space requirement in square feet for food storage for 30 days has been calculated by some as approximately one half the total served or, if 1,000 are served, 500 sq ft may be used as a tentative figure for total food storage needs. Cases of 6/10's stacked 6 cases high on flat trucks will have a bearing weight of approximately 250 to 300 lb per sq ft. Skid sizes should be 3 by 2½ ft by 8 to 12 in. high. Where heavy items, such as 10-gal cans of milk, are stored, bearing weights may be increased. One case of 6/10's, 24/2½'s, or 24/2's weighs approximately 50 lb and occupies 1 cu ft.

Common Storage The volume of canned food needed to serve 100 persons three meals daily for one month is estimated at approximately 45 cases of 6/10's or equivalent. The maximum stack height will be 8 or 9 cases or approximately 72 in. Accessibility of items that differ, as well as volume, will govern the number of stacks needed. A total of 3 cu. ft per stack is estimated to include floor space covered by a case of canned food, plus a share of aisle space. One thousand cases piled eight high in 125 stacks will require 375 sq ft or a storage area approximately 20 by 20 ft. Storeroom aisles may be as narrow as 36 in., but 42 or 48

TABLE 3 Square Feet of Kitchen Space per Meal for Food Facilities of Different Type and Size

Type of facility	Estimated maximum meals per hour				
	200 or less	200-400	400-800	800-1,300	1,300-7,500
Cafeterias	7.5-5.0	5.0-4.0	4.0-3.5	3.5-3.0	3.0-1.8
Hospitals	18.0-4.5	12.0-4.5	11.0-4.5	10.0-4.0	8.0-4.0

RESTAURANTS AND EATING PLACES

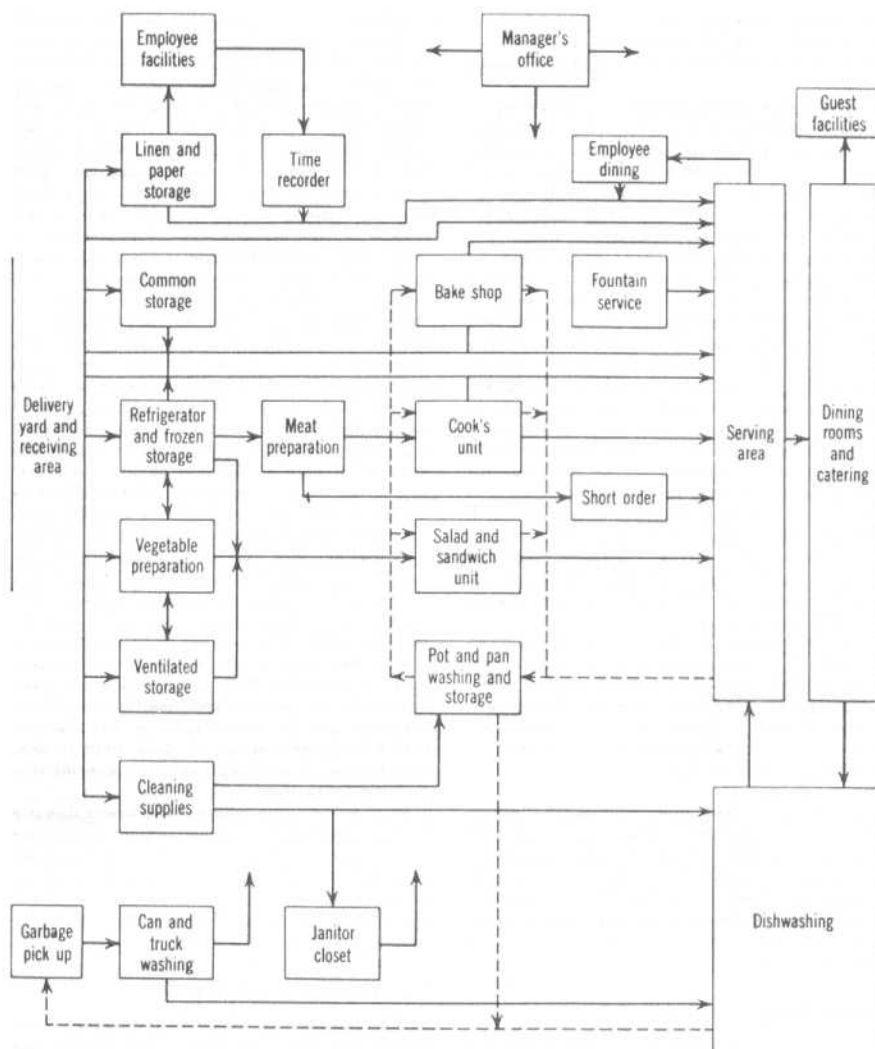

Fig. 1 Flow diagram showing functional relationships.

in. are preferred. Wider aisles may be required if trucks are used. A 3-ft skid on a hydraulic jack needs maneuvering room. If rolling bins or garbage cans on dollies are used for storage, plan location for these. If cans or bins are under shelves, adjust height of bottom shelf to clear and allow for work space for removing food from these containers. Fixed shelving will be best when planned to suit the sizes of items stored. Consider both interspace and depth suitable. Condiment bottles, cereal packages, and canned goods differ in package sizes and in stacking quality. The depth of a shelf should accommodate either the width or length of the case, and the interspace should be adequate for the number to be stacked one on top of another. Allow 1½ to 2 in. as free space for ease of positioning. Add thickness of shelving to interspace when stating measurements between centers.

Position heavy items to reduce lifting and facilitate dispensing. Drums of oil and vinegar should have spigots and be equipped with pumps or located on cradles. Table surface and scales should be located for convenient issuing of dry stores. Plan to have all products at least 6 in. above the floor or movable to facilitate cleaning of storage area. Limit height of top shelf for easy reach without aid of stool or stepladder. The average vertical reach of

men is 84 in. and of women 81 in. Use of the top shelf for light, bulky packages, such as cereal, is recommended.

Refrigerated and Low-Temperature Storage There are many factors affecting space needs for refrigerated and low-temperature foods. Across-the-board figures generally should be used only in preliminary estimates. The quantity stored at one time will dictate the storage needs. Variation in the type of storage also will be indicated by the types of items to be stored. Allocation in preliminary planning may be as follows: 20 to 35 percent for meat (portion-ready meats require ⅓ to ½ less space than carcass or wholesale cuts); 30 to 35 percent for fruits and vegetables; 20 to 25 percent for dairy products, including those in serving areas; 10 to 25 percent for frozen foods; and 5 to 10 percent for carry-over foods, salads, sandwich material, and bakery products. A requirement of 15 to 20 cu ft of refrigeration per 100 complete meals has also been used by some planners. Others state 1 to 1½ cu ft of usable refrigerator space should be provided for every three meals served. Analysis of a number of award-winning installations indicated that approximately 0.25 to 0.50 cu ft of refrigerated walk-in space was provided per meal served, and frozen walk-in space approxi-

mated 0.1 to 0.3 cu ft per meal served. Additional low-temperature or refrigerated space in terms of reach-ins was not calculated. In some climates, refrigerated space must be provided for dried fruits, nuts, cereals, and other foods to prevent weevil and insect infestation.

A walk-in becomes feasible for an operation serving 300 to 400 meals per day, and refrigerated pass-throughs can be added when from 400 to 500 meals are served per day. A walk-in 5 to 6 ft wide does not permit storage on both sides with adequate aisle space. Storage space of 1½ to 2 ft should be allowed on either side of the aisle. If crates or cases are stored, this may have to be increased. Aisles of 30 in. are usually too narrow; 42 in. are desirable. If mobile equipment is moved in and out, aisles may have to be wider. Walk-ins that are 8 to 9 ft wide and about 10 ft long are minimum size. This allows for two storage areas 30 in. wide with a 3 to 4 ft aisle. If added width is desired for storage space in the center, allowance for storage areas of about 3 ft wide and 42 in. minimum aisles should be provided. Large walk-ins may be designed for lift truck operation, with doors opening from the receiving dock on one side and into the kitchen opposite. If this is done and lift trucks are used, space must be provided in storage aisles for their working and turning around. Doors should be a minimum of 42 in. wide to admit large crates and containers or be sized to suit mobile equipment. Doors to low-temperature areas are most often planned to open into a refrigerated area. If this is not done a heating device may have to be installed on a door opening into a warm area to prevent its freezing tight from condensation. About 12 to 15 sq ft must be kept free for every door opening. About 45 lb of frozen food, if stacked in cases, can be stored per cubic foot. About 30 to 35 lb of refrigerated food can be stored per cubic foot.

Sanitation Areas

Dishwashing Area The space required for the dishwashing operation depends on the methods and equipment used. In all instances there must be adequate room to receive the volume of soiled dishes likely to arrive at any one time, plus space for scraping, stacking, and placing in baskets on a conveyor of a machine or into a prerinsing operation. The dimensions may be only 30 to 36 in. for a single tank machine, 60 to 72 in. for sinks, or 7 to over 30 ft for a conveyor-type machine. The requirements in the clean dish area will vary. It is important that there be enough space for dishes to be exposed to air for sufficient time to air-dry before stacking. For a basket-type machine, it is well to allow space equal to that required for three baskets, a stack of trays, and three or four stacks of dishes. For basket machines, it is usually recommended that the clean dish area occupy 66 percent of the total table space and the soiled dish area, 40 percent.

Methods used for transporting and storing dishes will influence space needs. Where mobile storage equipment is used, more space is needed for the several units than where one cart is used for transporting and is repeatedly loaded and unloaded. A table surface is desirable for sorting, treating, or inspecting silver and other tableware. The installation of a domestic washer and drier in the dishroom may require space.

Pot and Pan Section Provide a soiled utensil collection area adequate for the largest volume that normally arrives in the section at one time. The busiest periods are likely to occur when preparation containers are emptied for service

Y Bartender's aisle	2-0 to 2-2	2-6	3-0
Z Bar	2-3 to 2-6	2-5 to 2-6	2-8 to 2-9

CURVED TYPES: Radius R should be at least 2 ft.; other dimensions as for straight types.

Bar length: Allow from 1 ft. 8 in. to 1 ft. 10 in. per person for standup bars; 2 ft. for each stool.

Bar depth: No increase in depth is needed for more than 1 bartender, as each man should be provided with his own "set-up" space in the work counter and back-bar.

Service bars: These are usually from 6 to 8 ft. long, for 1-man service; from 10 to 12 ft. long if 2 bartenders are needed for peak service periods. No footrail, counter overhang, or stools are required. Location is often adjacent to kitchen and concealed from patrons; however, advertising values sometimes cause it to be set in public view. In the latter case, a rope rail or similar device, to discourage patrons from standing at the bar, is often advisable.

and immediately following service when service equipment is brought from the serving areas. A disposal or a removable strainer above a drain is desirable for waste removal.

When allowing space for the pot and pan section, 40 sq ft is generally regarded as a minimum for the smallest unit. The free work aisle between the sinks and other equipment should be 4 ft wide. The space allowance above the minimum will vary widely depending upon the type equipment used and the volume of pots and pans handled. Less space in relation to the maximum load may be required where a mechanical washer is used and fewer labor hours will be spent in handling a large volume per unit handled.

Miscellaneous Sanitation Areas For washing mobile equipment, space is needed where splashing can be confined and that has satisfactory drainage. This area may be adjacent to the dishwashing section or to the place where can washing is done. The size and type of equipment to be handled will govern the space needs.

A storage area for emergency cleanup equipment is needed in convenient relationship to dining rooms and work sections. Spillage and breakage create unsightliness and are accident hazards. Immediate care usually does not require heavy or large equipment but may be handled by a small broom, dustpan, small mop, and bucket not used for major cleaning. A mobile unit may be designed to carry these things, or a small closet may be provided.

Major cleaning equipment required will depend on the floors, finishes, and furniture to be cleaned. Determine whether a power sweeper, scrubber, and waxer are to be used. Space may be required for storage of janitor supply carts and for miscellaneous replacement items, such as light bulbs. Provision will be needed

dimensions in feet and inches

for storing, emptying, cleaning, and filling mop trucks and for cleaning and air-drying wet mops.

Employee Facilities

Facilities for employees may include locker and lounge area, toilets, showers, time-recording equipment, hand basins near work areas, and dining rooms. An employee entrance should be so located that the employees may go directly to the dressing rooms without passing through the dining room or production area.

Locker and Lounge Area Employee possessions should be protected in a suitably safe and sanitary condition while the employees are at work. Whether individual lockers or common cupboard, sufficient space should be allowed for personal clothing to hang without crowding or wrinkling. If cupboards are used for clothing, a separate space should be afforded for street clothing and for uniforms, and individual parcel lockers should be provided for storage of purses and other valuables. The height of the space for clothing should permit the longest garment to hang straight without wrinkling. The depth from front to back should be a minimum of 20 in.

Suitable size for an employee lounge depends largely on scheduling of workers and the policies of individual establishments. Many operators discourage lounging in the dressing room and recommend the employees' dining area for this. Others having broken shifts on their schedules favor an extra room for lounging. In all cases benches or chairs are to be provided upon which workers may sit while changing clothes and shoes. A cot or daybed, 36 in. by 6 ft, should be provided in the women's room.

Toilets and Showers The location of toilet facilities near work areas is preferred over a remote location in promoting good health habits, lessening loss of labor time, and permitting closer employee supervision. Separate facilities should be provided for men and women. They should be separated from food areas by a hallway or double entrance. Supply one wash bowl for every 8 to 10 workers, one toilet stool for every 12 to 15 women, and one urinal and one toilet stool for every 15 men. Toilet compartments measure approximately 3 by 4½ to 5 ft.

The type of employees, the climate, kind of work, and conditions of work will influence the need for shower facilities. Showers will be appreciated and used by employees working in hot, humid kitchens. Experience has demonstrated that they are little used in localities where the weather is cool most of the year, the work areas well ventilated, and workers drawn from an income group who have good facilities at home.

Time-recording Equipment Provide space for a recorder near and within view of the office. Wall-hung card racks of sufficient capacity are recommended for the number of workers, both full and part time, who are likely to be employed during an accounting period. Estimated space for a clock recorder is approximately 18 in. wide by 12½ in. deep and 18 in. high, and a rack of 50 cards approximately 1½ by 2½ by 34½ in.

General Considerations The size of employee facilities has been found to vary widely. Small operations may not supply lockers and may have only a toilet and lavatory for workers. Some do not provide separate dining areas. Expediency in allowing ample space may be tempered by cost of space, available room, and the acuteness of need. Total space used

RESTAURANTS AND EATING PLACES

Nondining Spaces

may be increased where main toilet and locker areas are remotely located and additional facilities are provided near work areas. It may be decreased where the food facility is a part of a larger organization providing facilities for other workers as in a hospital or in a hotel.

Guest Facilities

Comfort and cordiality should characterize the entrance and waiting area for guests. The size of the area should be based on probable need for waiting, type of service, and number of persons likely to congregate at one time. If there is a lounge or hallway adjacent to the dining room, this may provide some waiting space.

Locate the public telephone, coat rack, and toilet facilities in convenient relationship to the waiting area. In college dining rooms provide ample space for books as well as coats. In residences, a hallway approaching the dining room will lessen the wear on the lounge. Attractive benches or seats are recommended.

TABLE AND CHAIR UNITS

Data on space allocations and clearance contained in Figs. 2 to 8 is presented as an aid in determining capacities, desirable seating layouts, and necessary clearances. Information was furnished by the John Van Range Co. and Albert Pick Co., restaurant equipment specialists; Louis A. Brown, architect; and the Brunswick-Balke-Collender Co.

Tabulations are divided into three groups. The most luxurious establishments ordinarily use as minima the largest figures given, and vice-versa.

BOOTHS

There are, in some localities, code and other restrictions on booth furniture dimensions. Authorities having local jurisdiction should be consulted. One designer consulted regarded the 2-person booth (side-by side) as a waste of space; others recognize that conditions may arise when no other type of furniture will suffice. Booths for more than four persons are not commonly encountered.

NONDINING SPACES

Diagrams, tables and other data given in Fig. 9 and below illustrate only a few of the many types of nondining spaces and clearances required. Data included here may, however, suggest methods of solving most problems.

Cashier

Preferred location for the cashier's desk or counter, according to the Albert Pick Co., is on the right hand side of the door when leaving, in order to avoid cross-traffic and resulting congestion. Dimensions vary from those given in the table according to what merchandise is sold by the cashier and can best be determined in

conjunction with each job. If quantities of tobacco, etc., are sold, a back wall case may be necessary.

Coat Checking

Figure 9 illustrates only one type of check room layout; selection of type and size depends on the job under consideration. It is generally considered uneconomical, except in the most luxurious restaurants, to provide check rooms capable of accommodating garments for the peak load of patrons, for the following reasons: (1) Women usually do not check coats; (2) not all male patrons check coats; (3) space required can usually be used otherwise to greater advantage. The Albert Pick Co. estimates that approximately 5 garments can be hung per linear foot on each side of the type of racks diagrammed.

Use of coat trees in dining areas is termed "necessary but never desirable." These occupy approximately 20 by 20 in., are 72 in. high, and can accommodate 8 garments per customer. Overshoe racks are considered undesirable; umbrella racks, desirable in check rooms.

Telephone Facilities

Booths are usually preferred to telephone jacks, probably because of costs of installation and of relocating wiring when redecorating or replanning. Booths should be out of direct vision yet convenient to dining and lounge areas. One booth per 50 seats is the usual ratio or one phone jack per dining booth.

The greatest areas for efficiency in manufacturing have been in the areas of reduced work flow. Industrial engineers learned a long time ago that the movement of a product from one spot to another does not of itself improve the product. The process of moving takes time, costs money, is dehumanizing and may, in fact, cause product damage. Industry has evolved all types of imaginative methods for reducing travel and, where it was essential, cause it to happen with the least amount of human assistance and at the lowest possible cost.

The food service industry, until recently, has generally felt that these techniques were not appropriate, primarily because of the past availability of low-cost help and the acceptance of what were considered traditional work methods. With sharply rising labor costs and with the need for gaining the full productivity of technically trained people, the industry is rapidly adopting improved material handling concepts.

The evolution of a food service scheme which requires the smallest number of steps or distances to be traveled is developed using 80 percent common sense and 20 percent technical know-how. In planning a new or modernized facility, the designer must continually ask two questions: "Why?" and "How?" And the classic answer, "It's always been done this way," is no longer acceptable.

Since the architectural relationship, both horizontally and vertically, of the various elements in the project is the first consideration, the "why" question must be asked first at every step in the process. Many designers establish a work-flow plan before endeavoring to effect the interrelationship of the various areas. Each operation has its own unique features and only by continually asking at each step the question, "why," will the most effective plan evolve.

Usually foodstuffs are received and immediately stored. Generally there are refrigerated, frozen, and dry storage areas and these logically should be adjacent to receiving areas and should also be readily accessible to the preparation facilities. It is often appropriate to have not only major storage areas but also interim, smaller storage facilities. As the cost of labor increases, many designers are rethinking the old concept of having a single walk-in refrigerator, for example, and locating smaller process refrigerators strategically throughout the layout.

Certain of the preparation processes may be located in separate floors. A bakery, for example, may be tucked out of the way, but thought must be given to the flow of materials to and away from this area. Generally the plan is a continuous process, always moving forward from one step to the next, with backtracking or cross-overs limited as far as possible.

In most feeding operations, all of the production ultimately ends in the serving area, and care must be taken to establish the flow of the finished food to the customer, whether

it be in a sit-down dining room on the same floor or to patients in a multi-story hospital. This, in essence, comprises the heart of the primary work flow and if any steps can be eliminated in the process, this will be of benefit to those who will operate the facility.

In addition to this basic flow, we find peripheral flow patterns which may be cyclical in nature; for example, the preparation utensils have to be scraped, washed, stored, and then returned to the work areas; dining room serviceware undergoes a similar but more complex process. And during all the processes there is a generation of waste, sometimes from the receiving area; certainly from the preparation and serving areas, as well as from the washing facilities. All this waste material must travel to some point of disposal which in many cases is adjacent to the receiving area. The work flow in each of these supplementary processes likewise must be considered and minimized (Fig. 1).

There are other architectural features that must be considered in addition to the interrelation of the spaces: the proper height of loading trucks, the elimination of door saddles, walk-in refrigerators and freezers at floor level, the design of elevators and dumbwaiters which are the proper size and which stop floor flush and for loading.

The means or equipment necessary for the transport of food in process is the next consideration, and the question "how" must be answered. All things considered, the wheel is the basic "how." Wherever possible, dollies, trucks, carts, wagons and rolling racks should be employed.

The source of supply and method of delivery are the first considerations. There are many suppliers who offer their products palletized for quick, easy transfer to the receiving area. Others strap quantities of boxes together. The designer must concern himself not only with what is currently in practice but what might be done, and adapt his equipment to meet the nature of incoming products. Once in the building, various methods are used. Some facilities have been designed around a single tier rack which is used for everything from the initial receiving to final service. Other designs involve the use of a variety of special purpose vehicles: often the heavy duty platform truck, rolling shelves or movable pallets for the receiving and storing process; then going to special purpose pan racks for moving food in process to the serving area, with still other special purpose carts for soiled and clean dish handling. There are as many variations of these combinations as there are food service operations and there are trucks and carts for every conceivable use. It behooves the designer to make the selection of the proper carts in evolving the food service scheme.

Dumbwaiters, elevators, dish tables, serving counters, work tables, doorways and refrigerators all must be designed keeping in mind the specific vehicles to be used. In major installations, there are some exciting new concepts using carts which are transported by overhead monorails. Another new technique utilizes buried cables in the floor along which carts

move from place to place without assistance, following electric impulses in the cable.

There are special considerations to which the designer must address himself, such as security, supervision, safety and employee morale. Next to the banking business, the food service industry involves itself in a product which has great universal appeal. Security, therefore, must be an overriding consideration. On paper, the walk-in refrigerator that opens directly onto the loading area may seem great, but unfortunately, human nature being what it is, employees working where they would be out of view are often tempted to conspire to accept short deliveries or slip merchandise out for their own use. Receiving areas, therefore, should be open and visible to management.

Supervisors should be located in strategic areas where they have a commanding view of the important operations. Some schemes include elevated offices where supervisors can scan a major portion of the entire operation, seeing not only the preparation areas but also serving areas.

Safety considerations include providing adequate width of aisles, limiting weights on carts, protecting passageways adjacent to dangerous machinery, etc.

Employee morale is increasingly important. Minimizing the isolation of employees in dull storerooms by themselves can improve productivity.

It would be impossible for the designer to create all the work areas in such a fashion that transport was eliminated. It would also be impossible to make use of every special purpose cart available. It is the designer's job to weigh all of the factors involved and to consider frequency, quantities to be moved, the weights involved and then compromise these various relationships to come up with a workable scheme.

After the size of each area has been determined, many designers create a scheme of space relationships to the proper scale irrespective of the architectural configuration to which they must conform. And only after they have evolved the best theoretical scheme do they try to fit it into the space available. Unfortunately, in the past the work areas of the food service facility frequently have been left to the end and fitted in as best they could. With the tremendous cost of building, equipment and the mechanical services required plus the increasing cost of labor, this is one of the major planning considerations that should be given priority not only in the allocation of space but its relationships to food service and other building functions.

AISLE SPACE

Many of the problems which exist in kitchens are due to inadequate thought of the flow sequences of food through the kitchen. The matter of aisle spaces is of great importance in the food facility. There are some general rules, comments and recommendations which can be made for typical establishments.

1. Separate work and traffic aisles as much

Fig. 1 Ward galley. Work-flow rendering for a hospital food service program. (Cold distribution and ward heating method.)

as possible. This may be done by locating traffic aisles parallel or perpendicular to the working aisles.

2. Traffic aisles should be made to serve two departments where possible. Traffic aisles against walls can serve only the one department adjacent to the aisle.

3. Aisles around the perimeter of kitchen have several disadvantages:

a. They serve only one department.

b. They utilize a large area when compared to the remaining area. For example: a 5-ft-wide aisle running around the entire perimeter of a 40-sq-ft area uses almost 25 percent of the total area available.

c. Paths along the perimeter of a room are the longest paths available between departments, requiring increased moving time. Remember, movement per se adds nothing to a product except cost.

4. Traffic aisles and especially work aisles that are too wide require many extra steps, often while personnel are carrying relatively heavy loads. Aisles should be sized according to the guides above.

It is definitely not recommended to move traffic through aisles where workers must constantly cross between two stations on either side of the aisle. The width of the aisle becomes excessive and this could become dangerous (Fig. 2).

Work aisle guide	Width, in.
For 1 person working	24 to 36 (Keep to minimum)
For 2 persons working back to back	42
For personnel who must pass equipment which projects into the aisle	30 + the distance of projection into the aisle
Traffic aisle guide	
For 2 persons to pass	30
For 1 truck to pass one person— one-way traffic	24 + maximum truck width
For 2 trucks to pass—one-way traffic	20 + maximum truck width
For 2 trucks to pass—two-way traffic	30 + the sum of truck widths
Multi-usage aisle guide (these are not recom- mended but must sometimes be employed)	
For personnel passing 1 worker at his station	42
For personnel passing 2 workers, back-to-back at their stations	48
For trucks passing 2 workers, back-to-back at their stations	60 + truck width

LOCATING FOOD WASTE DISPOSERS

Food waste disposers can be supplied with a number of different type assemblies making them suitable for practically any position where food waste occurs.

When trying to decide upon the disposer and assembly most suitable for use at the soiled dish table, a number of questions should first be answered:

1. Is there sufficient room on the soiled dish table for a cone bowl or sink—or must space be conserved?

2. Will the disposer be used to handle preparation waste in addition to the waste returned to the dish table?

3. Will there be a quantity of milk containers and other paper waste to dispose of?

4. Will more than one operator be using the same machine?

5. Does the dishwashing machine have built-in prewash, or will the prerinsing operation be done over the disposer, or made a part of a machine incorporating both features?

6. Will compartment-type trays be used?

In installations where the unloading area for soiled dishes is very limited and the designer cannot afford the space that a cone bowl or sink requires, there is a disposer assembly that takes no more space than that allowed for a scrap-block. This would be strictly a disposer operation.

When the food waste disposer is to be used for disposing of both preparation waste and table scraps, the assembly should have built-in flexibility. A cone bowl with removable stainless steel sleeve offers this. With the stainless steel perforated sleeve removed, the cone bowl becomes a large receiving hopper—one that accepts leafy waste with ease. With the stainless steel perforated sleeve and scrap-block in position, the assembly is then suitable for scraping of waste and control of silverware that might accidentally be pulled or dropped into the cone bowl.

Overhead prerinse can be installed above the disposer if desired. However, it is difficult to prevent the stream from traveling over the table. Recessing the cone bowl in a shallow sink will assist in confining the rinse water.

When one disposer is to be used by two or more operators, placement of the machine and the design of the table takes on added importance. Where two operators are to use one machine, an island type of installation satisfies the requirement. If more than two operators are to be served by one disposer, a trough is most suitable.

Knowing that the scraping of waste is but the first step toward preparing tableware for the washing operation and that size and type of dishwashing machine governs the amount of preparatory work needed, you may be interested in two machines that incorporate disposers which have been specifically designed for work ahead of the dishwasher machine.

When working ahead of a dishwashing machine that does not incorporate prewash, the preparatory operation must be performed as a separate operation in the prewash sink or as a scraping, preflushing, and disposing and this makes for an excellent preparatory operation. Basically this machine consists of a wash tank, a recirculation pump, a separator conveyor, silver-salvage basin and a food waste disposer.

The machine should occupy a position between the point where the soiled dishes land and where they are to be sorted while waiting to be racked.

Since water may be used to transport waste from the food waste disposer, this machine first uses the water for scraping, then reuses it as a transporting medium. For most efficient operation, the machine should be used while sorting, as a combined, rather than a separate operation.

Sorted tableware that is waiting to be racked carries sufficient water to actually soak small pieces of food waste that may still be clinging to the tableware.

On the dish table installations where there will be two or more operators preparing tableware at the soiled dish table and where the dishwashing machine incorporates built-in prewash, a trough type scraping and disposing operation offers speed and flexibility. The operators then can move to the work load rather than moving the load to some one position. An installation of this type can be one

that uses fresh water flowing within the trough or one where there is a large volume of recirculated water mixed with a small amount of fresh water conveying the waste to the food waste disposer.

In planning for the most suitable installation, thought must be given to the width and length of the trough and whether it will be straight, L shape, or some other design.

If the trough is short and straight, a fresh water trough installation works well. The disposer is usually attached to the lower end of the trough section and the fresh water brought in at the opposite end and at intermediate positions along the trough. Since water is the carrying agent for the ground food waste leaving the disposer, a trough installation offers double usage for the water as it is first used to move the scraped waste along the trough to the disposer. The same water is then used to transport the ground waste to the sewage system.

In installations where a recirculating water conveyor and food waste disposer is to be used in conjunction with a trough application, the designer or consultant is permitted to use imagination in his planning. L-shape or U-shape troughs serving an entire area can become reality where there is 65 to 70 gallons per minute of recirculated water with which to work.

With quantities of water moving in a trough, waste moves freely without operator assistance. On some installations tableware is actually presoaked in certain sections of the prefabricated trough without interfering with the forward flow of food waste to the disposer.

Vegetable Preparation

When choosing a food waste disposer for installation for a vegetable preparation area, the designer should keep in mind that he will be wanting to dispose of large, leafy waste, and the opening into the disposer should be able to handle this waste. He should choose an assembly along with the disposer that offers this convenience.

Where there is to be a fairly heavy work load in the vegetable preparation area, some consultants have found a two-compartment sink desirable. The first compartment measures 24 by 36 by 6 in. It is here the trimming and disposing of food waste takes place. The vegetables are then rinsed in the second compartment that measures 18 by 24 by 12 in.

Should a designer choose to install the disposer in the work table adjoining a sink, there are a number of assemblies that are designed for this application. Generally, the assembly consists of a cone bowl fitted with a rubber scrap block. Water can either be directed into the cone bowl through a water inlet elbow or an elevated gooseneck. With the latter type of inlet, the water serves a double purpose in that the vegetables can be washed under the stream. The water entering the disposer then carries the ground waste through the waste line.

Pot Sink

The pot and pan area is another location where consideration should be given to the installation of a food waste disposer because there is considerable amount of waste returned on the utensils.

The disposer can be fitted with a sink drain fitting and installed at the base of the sink or included with a suitable assembly and made a part of the work table adjoining the sinks.

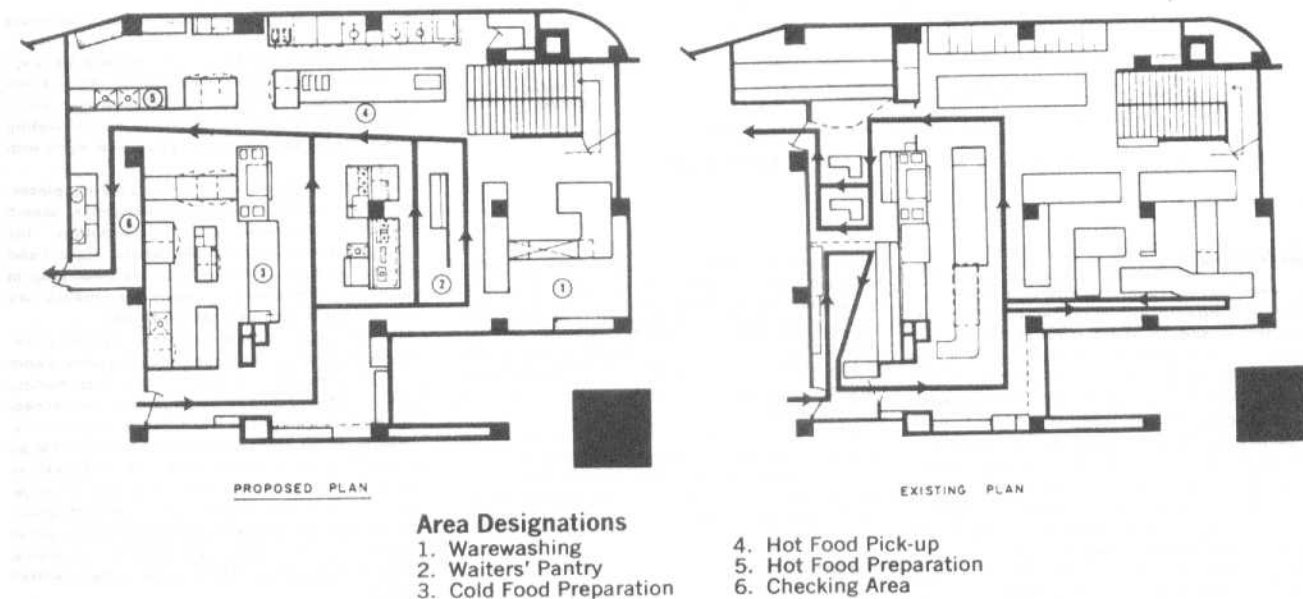

Fig. 2 Movement through traffic aisle at the cafe/bar kitchen facilities, Hotel Commodore.

Although there is no hard and fast rule when choosing the proper size disposer, there is a relationship between horsepower, size of opening to the disposer and the size of the grinding chamber.

THE MAIN COOKING AREA

The main cooking department is the heart of the kitchen and deserves special care in designing. Both meat and vegetables are usually cooked in this area. Serving in table service restaurants may take place from or near this area. In other installations, the cooked food is transported a considerable distance to the serving area. In general, it has been found advisable to cook such items as vegetables in small batches as close as possible to the serving time. This consideration requires that at least the vegetable cooking should be done as near to the serving area as possible. In fact, some installations utilizing cafeteria counters have provided small, high speed vegetable steamers directly on the cafeteria counter.

Meats may be prepared in large batches but the trend is towards staggering of the start and completion of meat cooking even though no equipment may be saved because of the long processing time as compared to the serving period.

The trend in the design of the main cooking area has been towards the provision of roast ovens separate from the ranges. This reduces friction between those using range top and the oven.

The flow chart below indicates the relation of the main cooking area to the other kitchen departments. (Fig. 3.)

Fig. 3

The layout of the main cooking department varies greatly from installation to installation. In general, the table service restaurant will serve from this area, and this requires consideration. In many cases where food is cooked to order, insufficient refrigerated or frozen food storage space has been provided in the main cooking area.

Several considerations are necessary before typical departmental layouts are presented.

1. The broiler should be at the end of the line—away from the traffic in front of the cooking equipment. Adequate refrigeration and work space should be provided for the broiler operator.

Traditional French kitchen arrangements assign the broiling, carving and roasting duties to the broiler operator. It is not always necessary to follow this practice in today's kitchens.

2. Fryers may be located near the broiler if the same person will operate them or they may be located at the far end of the range battery. Sufficient work table space and an area to drain fried foods must be provided in addition to refrigeration and in some cases freezer storage space.

3. The steam table or serving area, if it is to be from the same area as cooking, should be near the broilers and fryers.

4. The space between cook's table and cooking equipment should be at a minimum but should provide for opening of range ovens, steamers, etc. If traffic or trucks are anticipated, greater space than normal is required.

5. All heat-producing equipment should be vented to an effective exhaust hood. Local laws should also be checked on this point.

6. Equipment which is placed against a wall should have sufficient space for cleaning behind the equipment. One to two feet are recommended.

7. It is preferable to provide breaks in extended cook's or serving tables for access by cooks. Extended parallel, back-to-back arrangements may require breaks in the equipment for similar reasons.

8. Plate warming facilities have traditionally been placed in front of the cook's table in

waiter service restaurants. The trend, however, has been toward provision of plate warming facilities which are directly accessible to the servers.

PREPARATION AREAS

Meat Preparation

The meat preparation departments take meats as delivered and convert them into products suitable for further processing in the main cooking area. The specific duties of this department have changed significantly in recent years. There was a time when cooks did most of the preparation at the main cooking area. This gave way to a meat preparation department where butchers prepared the meats for the cooks. The meat was then issued to the cooking department in such a ready-to-cook quantity that portion control was readily obtainable. The trend now, in all but the very large installation, has been towards the increasing purchase of meat in a ready-to-cook state. The theory, which often is valid, is that the various packing houses with their skilled mass-production workers can perform this operation more economically. A further benefit is that meat storage space is decreased—often up to 40 percent—by the purchase of ready-to-cook meats.

The flow chart for a typical meat preparation area with its relationships to the other kitchen departments is shown in Fig. 4.

Holding in a refrigerated area may precede cooking. In some instances, meats are prepared a day or more prior to cooking.

Fig. 4

Commercial KITCHENS

Fig. 5

Salad Preparation

The salad preparation section utilizes ingredients prepared in the vegetable preparation section and/or items from the fruit and vegetable refrigerator. Some minor amount of meat and dairy products may also be used in various salads. In table service restaurants, the salad departments may be included with the pantry or *garde manger*. Such typical departments are shown with the serving departments. Some installations, however, combine the salad and vegetable preparation departments. In those installations using cafeteria counters, the salads pass directly from the salad preparation area to the counter. Pass through refrigerators are quite useful in minimizing the steps required to service the cafeteria counter especially if salads will be prepared during the serving period.

The flow chart (Fig. 5) for a typical preparation area shows the relationship of this department to the other kitchen departments. The number of trips, method of transportation and amounts which are to be transported between the departments should determine the relative location of the salad preparation area. For example, if salads are to be made with a constant flow of materials from the vegetable preparation department and a storing of completed salads in mobile refrigerated trucks until ready for moving to the service area, then the location of this department should be as close to the vegetable preparation department and refrigerator as possible. With such a production system, it is not necessary to locate this department near the service facilities. On the other hand, supplies may be batch delivered and a constant flow of salads to the serving areas will be maintained. For such an operation the location of the salad preparation area should favor the serving facilities.

The work methods to be followed in the preparation of salads determine the precise layout of this department. As with the other kitchen departments, food should flow as much as possible in a continuous direction from the start of the department through processing and on to the next department. Some installations, especially those processing large numbers of the same or similar salads, are able to apply the principles of mass production and mass assembly to the design of the salad preparation department.

Vegetable Preparation

The vegetable preparation department prepares fresh vegetables for cooking and salads. In some installations, as previously noted, vegetables used in salads are prepared in the salad preparation department. Prior to the layout of this department, the precise functions and operations which will be performed should be determined.

The flow chart for the vegetable preparation area (Fig. 6) shows its relationship to the other departments in the kitchen.

In many instances vegetables are prepared the day before their usage by the salad and

main cooking units. In such cases the prepared vegetables must be stored in holding refrigerators. The vegetable refrigerator is usually used for this purpose, but very large installations and those installations which do not have the walk-in refrigerators on the same floor as preparation and cooking will provide holding refrigerators.

The layout of the vegetable preparation should follow as closely as possible the processing steps. Typical layouts vary depending on the state of the raw materials and the operations to be performed.

Sandwich Stations

Efficient food production requires planned arrangement of equipment. The size of the operations to be handled will determine dimensions. It must provide ample space for ingredients, tools and a logical work flow. The height must permit the worker to maintain good posture, use the least amount of energy, and stand in a relaxed position. Where short handled tools are used, the average recommended height is 36 in. Allow adequate toe space at the bottom edge of counter. The width of the work counter must provide comfortable reaching areas, without the necessity of the worker stretching. Sixteen inches from each elbow in all working directions is the average comfortable reaching areas, without the necessity of the worker stretching.

A counter top of hard maple or synthetic rubber-plastic composition is preferred. If the installation has a metal or other top, a large cutting block with a hard surface can be placed on it. Have counter top project at least 1 1/2 inches beyond the front of unit to prevent crumbs from collecting on shelf or door gasket below.

Provide a food-waste container recessed in the right hand side of the counter for "as you go" cleaning of the working surface. It should be easily accessible for removal, emptying and cleaning.

Both the placement angle of the filling containers and their sequence arrangement for left to right working of the sandwich maker will streamline operations. The fillings are more accessible if the containers tilt slightly forward toward the worker. Spreading of sandwiches is an automatic reach-and-touch procedure if

each filling container is put in its customary place.

The "in-use" bread supply should be kept at the left of the sandwich board. Many food-service establishments use a container which holds 3 to 4 varieties of bread or a self-leveling bread dispenser which moves each slice into position.

For the efficient handling of serving plates, there is a self-leveling dish dispenser, which allows the dishes to "pop" into position. This equipment can be recessed at the right hand corner of the counter top for the final step in sandwich preparation. These dispensers are available with hot or cold controls.

Select toasters and grills for performance, capacity, thermostatic controls, and easy cleaning. Production volume is the determining factor in their size and arrangement, but accessibility to the worker is of prime importance.

Adjacent to the sandwich center should be a double compartment sink. In installations where the salad and sandwich centers are adjacent, this sink can, of course, serve both units.

Provide an accessible storage area for small working tools, such as knives, spatulas, scoops, spoons, cutters, and other related equipment.

The layout of a sandwich center must often fit different shaped spaces. The equipment listed above can be arranged in a straight line, a U-shape, a circle, a corner, or as an aisle. In each available space, the equipment should be arranged as efficiently as possible.

WORK FLOW IN OTHER AREAS

Serving Facilities

The type and arrangement of serving facilities varies greatly from installation to installation. Restaurants use pantries and range batteries. Employee feeding facilities use cafeterias, snack bars, etc. Hospitals use tray makeup conveyors, cafeterias for employees and staff, and sometimes decentralized tray makeup facilities as floor pantries.

The major service departments in a table service restaurant are the range battery and pantry. The departmental layouts for the main cooking department illustrate typical arrangements of this area with provisions for service. The pantry and cold service are often united in one area of the kitchen. In other installations, salads and cold meats are prepared in one area and desserts, beverages, and some other items in the pantry.

The trend seems toward the combination of these two areas and toward the movement of many of the pantry items as rolls, butter and beverages to waitress stations located at strategic points in the dining room. Self-service of salad, cold meat and pantry items by the waiters and waitresses is ever increasing in

Fig. 6

table service restaurants, especially if speed of service and minimization of kitchen workers is of importance.

Bake Shop

Of all the preparation departments which might be located away from the main kitchen, the bake shop is usually least affected by such a location. The major differences of a remote bake shop are the requirements of additional pot washing and refrigeration facilities. Ovens should then be located in the bake shop, and this usually prevents their dual usage by the main cooking department.

Though some food service installations still prepare their own yeast breads, it is generally advisable to have this service rendered by a commercial bakery. Some bakeries will prepare yeast breads to special order if demand is sufficient. The completely self-contained installations and some of those featuring specialties do—and will continue to—prepare their own yeast breads.

Many installations do prepare pastries on the premises.

Successful freezing of prepared items for baking has enabled the typical shop to become much more efficient in recent years. Studies have shown that freezing of some items may even be helpful with respect to the quality of the finished product. This has made it possible to prepare relatively large quantities of an item using mass production techniques of preparation and baking them as needed. For such as operation, a freezer capable of freezing as well as storing prepared items is necessary. Such a freezer is called a sharp freezer.

In general, the bake shop should be near the storage area, both dry and refrigerated, and near the pot washing area. Location near serving facilities is of relatively minor importance if mobile racks are used to transfer sufficient quantities of baked goods to minimize the number of trips required. The flow chart (Fig. 7)

Fig. 7

shows the relationship of the typical bake shop to the other kitchen departments.

The layout within the bake shop should follow the typical processing steps as much as possible. The oven should be near the landing table with sufficient space in front of the oven to remove baked goods with a peel which reaches to the innermost corners of the oven. In general, as much clear space should be provided in front of a bake oven as the bake oven is deep, front to back. The proof box should be near the oven as should the baker's table. The mixer, pastry stove or hot plate and steam-jacketed kettle, if used, should be near the baker's table.

Fig. 8

Refrigerated Storage

The production processes in a kitchen are characterized by relatively few receipts of refrigerated supplies compared to movements between the refrigerated storage area and the preparation departments. For this reason, it is suggested that location of the refrigerated storage be close to the preparation departments (see Fig. 8).

In some instances the flow chart will be modified by preparation procedures which are to be followed. For example, some installations will partially prepare vegetables prior to storage.

Too often when the refrigerated storage areas and preparation departments are located on different floors, the time required to wait for elevators is excessive.

Another arrangement is to have the refrigerated storage and preparation departments near receiving, then move to the final preparation and production departments. This arrangement is better than that above but is still limited by vertical transportation. An advantage of such a location is that the part of the meat and vegetables which is scrap is closer to the garbage storage area.

In general it is recommended that the freezer storage open into a refrigerator rather than directly into the warmer kitchen. With such an arrangement, the refrigerator might be made for dual purpose usage, as a refrigerator or freezer. This will probably be quite useful in the future with the trend toward increasing usage of frozen foods. An alternate location of the storage freezer is near the main cooking area. This minimizes the distance traveled on the part of the cooks in obtaining food which is purchased in a ready to cook state.

Dishwashing

In the past, extreme emphasis was placed on locating this department either adjacent to a cafeteria service dining room or as the first "port-of-call" in a kitchen serving a table service dining room. With the increasing usage of vertical and horizontal conveyors, this becomes of lesser importance, and increasing attention can be placed on locating the dishwashing area near the location of dish usage—the serving and/or preparation areas as the mode of operation dictates. It is not unusual, nor impractical, to locate the dishwashing on a floor other than the dining room floor.

A separate dishwashing room which is well ventilated, lighted and has noise-absorbing surfaces will be found a great aid in lowering the high—often objectionably high—noise level commonly found in kitchens.

The large operation utilizing horizontal conveyors can apply industrial engineering principles to the breakdown of patron or patient trays.

Glass washing, long a major problem in food service, is now being better handled largely through the control of washing, rinsing and water additions. In most instances, it is not at all impractical to wash glasses in the same machine as dishes, if they are washed shortly after the water has been changed. Other installations utilize a glass washer with a separate soiled glass table or use the same tables as for soiled dishes.

Some installations, especially larger hotels, find it necessary to provide a separate silver room where hollowware may be correctly cleaned, burnished and maintained. Such an area usually can provide a better means for control of expensive silver.

The flow chart (Fig. 9) shows the typical relationship of this department to others within the food service installation.

Fig. 9

Pot Washing

Many smaller installations try to utilize the same sinks for pot washing and vegetable or salad preparation. This practice is not recommended. A minimum of two compartments—preferably three compartments with a grease or skimmer compartment between the first two compartments—is recommended. The main cooking, baking and serving departments are the major source of pots, pans and other utensils. In many installations, a relatively large storage area for soiled pots is required as they are not washed at the same time as received in the pot washing department. This is especially true if the same personnel operate the dishwashing machines and the pot washing department.

Fig. 10

The flow chart for a typical pot washing department is shown in Fig. 10. Note that pot, pan and utensil storage, while not shown on the flow chart, must be considered. This is apt to occur in each department from which pots arrive and in two places in the pot washing area: prior to cleaning and subsequent to cleaning.

KITCHENS

By Max Fengler

KITCHEN PERSONNEL AND THEIR FUNCTIONS

- Chef de cuisine (kitchen chef) is responsible for purchase of goods, cost control, setting up the menu, and supervision of personnel and hygiene in the kitchen area.

- Sous-chef (kitchen chef's assistant) represents the kitchen chef in his absence; in a large organization, he takes over some of the chef's duties.

- Saucier (sauce cook) prepares all sauces and the meals that go with them, as well as all fish dishes (although in large organizations there is a poissonier); he is responsible for the work at the kitchen range, and in medium-sized establishments he assumes the functions of the chef's assistant.

- Rotisseur (roast, fry, and grill cook)

In large restaurants, there is, in addition, a grilladin.

- Entremetier (soup, vegetable, and side-dish cook)

In large restaurants a potager prepares soups and broths.

- Garde-manger supplies the ready-to-cut meat and fish preparation, the cold appetizers, hors d'oeuvres, and salads. In large restaurants, this work is divided between the hors d'oeuvrier (appetizer cook) and the boucher (butcher).

- Pâtissier makes cookies, cakes, ice cream, and other desserts; in large restaurants, the work is divided among the glacier (ice cream maker), confiseur (fine pastry cook), and boulanger (baker of bread, rolls, and other baked goods).

- Commis (junior cook) is available to chefs of sections.

- Salad man or girl produces and serves various kinds of salads and in some restaurants is responsible for the smorgasbord (hors d'oeuvres) and is subordinate to the gardemanger.

- Casserolier cleans, cares for, and services all pans, cooking equipment, and kitchen machines.

- Kitchen boy cleans the kitchen, helps with the preparation of dishes, and has other duties.

- Contrôleur is in charge of supplies, controls their placement and storage, and does the inventory bookkeeping.

- Gouvernante accepts goods, exercises control, supervises the economat, dry storage, linen, and cleaning materials, and hands out staples.

- In European restaurants, the bar lady is responsible for all beverages and often is the representative for the management, and, in smaller restaurants, oversees the waiters.

- Argentier is responsible for the care of silver.

- Office boy

- Dish washer

Fig. 1 Hotel or restaurant kitchen or French restaurant of high standard. Capacity for main meals: Hotel—100–200 persons / menu, 100 persons / à la carte. Restaurant—200–300 persons / mealtime from 11:30 to 1:30. Waiters' passageway: tangential. Kitchen: Linear arrangement with large installations in the rear. See Legend for explanation of numbers.

Fig. 2 Hotel or restaurant kitchen. Capacity: With this layout, a 200-seat restaurant will be able to handle three full sittings. This layout can also take care of a hotel with 100 guests and can also accommodate a restaurant open to the general public, an outdoor restaurant, and a private dining area for parties and conferences (altogether, 400 guests). Waiters' passageway: in the center. Kitchen: Linear arrangement with large installations in the rear. See Legend for explanation of numbers.

Fig. 3 Large restaurant kitchen for restaurants with many private party and conference facilities or with commissary and catering capacity for other businesses. Suitable also for large hotel with large restaurant for the general public. Capacity: 800–1,000 persons (e.g., 200 seats and fourfold reoccupancy). Waiters' passageway: tangential, with food buffet situated in front. The waiter has access to beverages and other items from the waiters' passageway in the kitchen and from the dining room side as well. The buffet looks over the dining rooms. Kitchen: Linear arrangement with fitted berths for large apparatus. See Legend for explanation of numbers.

Fig. 4 Restaurant kitchen especially suited for city or excursion restaurants. Capacity: as in Fig. 1. Waiters' passageway: tangential. Kitchen: The cooking, roasting, grill, and frying apparatus are planned as wall structures. See Legend for explanation of numbers.

Fig. 5 Restaurant kitchen. Capacity: This arrangement is conceived for a very busy city restaurant of good quality (approximately 600 persons—e.g., 150 seats with fourfold reoccupancy). Waiters' passageway: in the center. Kitchen: The cooking, roasting, grill, and frying apparatus are planned as wall structures. See Legend for explanation of numbers.

Fig. 6 Large restaurant kitchen for restaurants with many auxiliary rooms, bowling alleys, garden, and a snack bar projecting into the main dining room. Suitable for a highly frequented city restaurant or for an excursion spot with various conference rooms, etc. Capacity: 1,000–1,200 persons. Waiters' passageway: tangential. Buffet and washing-up zone (dish return) placed in front. The waiter can pick up drinks and other items at two places in the kitchen, the drinks coming partly from the bar. Kitchen: Warm kitchen as wall structure with central serving area; cold kitchen and pastry area divided with two serving areas each, symmetrically arranged. See Legend for explanation of numbers.

Legend for Restaurant and Hotel Kitchen Layouts (Figs. 1 to 6)

(Layouts: Scale 1:300)

1. Waiters' passageway—meal and beverage counter—dish return
2. Dishwashing area (dishes, glasses, silver)
3. Beverages—preparation and serving
4. Pastry (cookies, cakes, ice cream, dessert)—preparation and serving
5. Cold kitchen (cold appetizers, salad, fish)—preparation and serving
6. Warm kitchen—saucier/rôtisseur area (sauces, roasts, grill, fish)—preparation including large apparatus area and serving
7. Warm kitchen—entremétier area (soups, vegetables, entrées)—preparation including large apparatus area and serving
8. Pot and pan washing—casserolier area
9. Vegetable preparation
10. Meat preparation
11. Vegetable cold storage
12. Meat cold storage
13. Economat (dry storage)
14. Beverage cold storage
15. Linen, dish, cleaning supplies storage
16. Staple goods storage
17. Goods acceptance and control
18. Empty goods and garbage collecting rooms

Fig. 7 Snack bar (Pub, tavern, bistro, café, or restaurant). Capacity: 55–60 seats (five- or six-fold reoccupancy over lunchtime, twofold in the evening; at other times, a well-run café, cake, and snack business). The kitchen deals primarily with ready-to-serve articles. In a city business with daily delivery, the storage space does not have to be especially large.

Legend:

1. Meal and beverage serving counter
2. Dishwasher
- 2a. Dish return
3. Beverage buffet with mixer, toaster, ice-cream container, etc.
4. Oven and small pastry station
5. Garde-manger
6. Saucier/rôtisseur
- 6/7. Range
7. Entremétier
- 7a. Cooking vat and high-performance steam cooker
- 6/7b. Warming cupboard and warm serving counter with warming lamps
8. Pot and pan washing
11. Storage, empty goods, office; instead of cold storage rooms—cold storage and freezer cupboards
19. Employees' toilets
- G1. Bar counter—also for meals
- G2. Dining room with table seating
- G3. Guests' toilets/make-up room/telephone booths

KITCHENS

Fig. 8 Self-service restaurant suitable for department stores or office buildings. Kitchen: no independent production; outside delivery and preparation via deep-freeze, boiling-in-the-bag (Nacka), or Régéthermic methods.

Legend:

- 1d. Self-service buffet with grill and fry unit
- 1e. Salad dressings, spices, cutlery reserves
- 1f. Cashier
- 2. Dishwasher
- 2a. Dish return
- 3/4. Sandwich unit, cakes, ice cream, coffee, beverages; service available at an outdoor café
- 5a. Cold preparation table
- 6/7. Defrosting, warming-up apparatus front, serviceable on two sides (convection ovens, heating appliances for the Nacka system or Régéthermic ovens)
- 11. Cold storage and storage (varies in size according to system of servicing and rhythm of delivery)
- 11a. Refrigerator front, serviceable on two sides
- 11b. Delivery, empty goods, intermediary storage, personnel cloak-room
- 12. Kiosk—sales on the inside and to customers on the street
- E1. Entrance from street
- E2. Entrance from building (department store, office building, etc.)

Fig. 9 Restaurant with finger-shaped bar and automats for quick lunch service in restaurants for passersby, cafeterias, department stores, highway restaurants. Capacity: 500 persons per hour. Kitchen: preparation of precooked meals, salads, and ice cream.

Legend:

- 1. Service passage for U-shaped or finger-shaped counter
- 1d. Automats for self-service
- 2. Connection of two fingers with dishwasher having two covers serviceable on both sides; adjoining are two sinks each
- 3. Coffee machine, refrigerators, soup vat storage
- 4/5. Salad and ice cream preparation
- 4/5a. Cold counter—salad, ice cream, dessert
- 6/7. Frying pan, soup cooker, and other cooking equipment
- 6/7a. Warm counter—bain-marie, fryer, grill plates
- 11. Economat, cold storage, and freezer space, staples room (delivery, empty goods room, office, personnel cloakrooms and washrooms not included)
- G. Guest rooms with standing room and seats (automat service with disposable dishes)

Fig. 10 Restaurant for travelers (Highway restaurant, or café-restaurant) at a busy intersection in the city). Capacity:

- Snack—45–50 seats (200 persons every hour)
- Restaurant—80 seats—(two- or threefold reoccupancy during meals; at other times, coffee, ice cream, pastry, and sandwich service)
- Grill—40 seats (one- or twofold reoccupancy, high standard service)

Kitchen: Linear-wall arrangement, approximately equal balance between freshly prepared meals and ready-to-serve meals. Storage, empty goods, and personnel cloakrooms in the cellar.

Legend:

1. Waiters' passageway
- 1a. Service corridor for snacks, and cold meal and pastry-serving counter for restaurant
- 1/3. Waiters—Beverage self-service
2. Dishwasher
4. Pastry
5. Cold kitchen
- 6/7. Warm kitchen (roast, grill, fry), bain-marie in the serving counter
- 6/7a. Cooking and frying apparatus (2 vats, 1 pan)
8. Pot and pan washing
- 9/10. Meat and vegetable preparation
11. Storage for the day
- 11a. Cupboard group, cooled and not cooled
12. Kiosk facing the street
- 12a. Cigarette machine
17. Goods delivery
- 17a. Office
- 17b. Elevator to cellar
19. Employee toilets
- G1. Snack area with about 40 seats and seats at the bar
- G2. Restaurant
- G3. Grill restaurant, possibly with small bar for espresso coffee, aperitifs, whisky, and other spirits
- G4. Guests' toilets

Fig. 11 Large hotel-restaurant kitchen also for large restaurants with some auxiliary rooms and with outside deliveries or production for other organizations (variant of Figs. 3 and 6). Capacity: 800–1000 persons. Waiters' passageway: in the center, with a special serving link to the garden (or, for instance, to a bowling alley) and directly connecting to the auxiliary rooms. Kitchen: Linear arrangement with rear side of large apparatus.

Legend:

1. Waiters' passageway
- 1a. Meal and beverage serving to garden
- 1b. Access to auxiliary rooms
2. Dishwashing area
3. Beverage serving area
- 3a. Beverage cold storage (day cellar)
4. Pastry
5. Cold kitchen
6. Warm kitchen—saucier / rôtisseur area
7. Warm kitchen—entremétier area
8. Pot and pan washing
9. Vegetable preparation
10. Meat preparation
11. Cold storage and storage rooms
- 11a. Accesses to delivery, empty goods room, and intermediary storage, office, personnel cloakrooms and toilets
- S. Service accessories (cash register)

Fig. 12 Café-restaurant with tearoom, or a city restaurant in a busy district.

- Café: alcohol-free beverages, except for bottled beer; pastry and small meals—cold and warm
- Tearoom: alcohol-free beverages, pastry, sandwiches. Capacity: About 150 seats (continuous service from early morning to midnight or later). Kitchen: extensive use of precooked meals; little storage.

Legend:

1. Waiters' passageway
- 1a. Serving stations and cash register
2. Dishwasher
3. Beverage buffet with mixer, toaster, ice cream container, etc.
4. Pastry
- 4a. Pastry oven
5. Sandwich unit
6. Defrosting and heating equipment, soup vats
7. Oven, grill, frying apparatus
8. Pot and pan washing
11. Day stores, empty goods (staple goods in cellar)
15. Linen storage
17. Delivery
- 17a. Office
19. Employees' washrooms, cloakroom for waiters (cloakroom and washrooms for kitchen employees in cellar)
- G1. Tearoom
- G2. Café-restaurant
- G3. Terrace or garden
- G4. Washrooms
- G5. Telephone booths

Fig. 13 Student dining hall or cafeteria with two-sided self-service buffet and conveyor belt. Capacity: 12 persons per minute \times 2 = 24 persons. Without cash payment: hourly capacity, 1,400 persons. With cash circulation: hourly capacity, 1,100 persons. Seating: at least 340 seats. Kitchen: fully equipped linear arrangement, planned for automatic equipment.

Legend:

- | | |
|--|---|
| 1a. Platter and cutlery trolley | 2a. Soiled-dish conveyor belt |
| 1b. Distribution help, regulation of conveyor-belt speed, dietary food storage | 4. Pastry |
| 1c. Conveyor belt for standard menu | 5. Garde-manger |
| 1d. Self-service buffet—Menu: | 5a. Portioning table for cold meals, salads, and desserts |
| 1 soup of the day | 6. Roast kitchen, possibly with roasting automats |
| 1 stew | 6a. Warm-storage trolleys—portioning of meat, sauces, dietary foods |
| 1 standard menu | 7. Cooking kitchen, possibly with automatic steam cookers |
| 1 dietary food | 7a. Warm-storage trolleys for portioning of vegetables, entrées |
| 2 cold meals | 9. Vegetable preparation |
| 1e. Salad dressings, condiments, cutlery | 10. Meat preparation |
| 1f. Cash register | 11. Access to the storage rooms, delivery, and auxiliary rooms |
| 2. Dishwasher | |

Fig. 14 Student dining hall or cafeteria with four self-service buffets. Capacity: at least 1,500 persons per hour. Seating: at least 400 seats. Kitchen: outside delivery of meals with standard or conveyor-type elevator.

Legend:

- | |
|---|
| 1d. Self-service buffet—menu as in Fig. 13 |
| 1e. Circular device for salad dressings, condiments, extra cutlery, etc. |
| 1f. Cash register |
| 1g. Preparation table with trolley stand |
| 2. Dishwasher |
| 2a. Soiled-dish return |
| 11. Standard or conveyor-type elevator connection to meal-preparation kitchen |

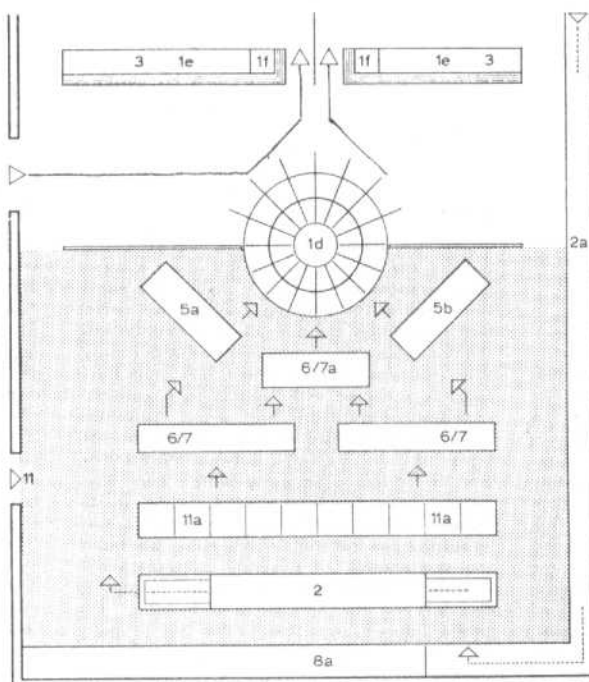

Fig. 15 Student dining hall or cafeteria with self-service carousel. Capacity: after the initial phase, 1,400 persons per hour. Seating: at least 400 seats. Meal delivery from a central kitchen—deep-freeze, boil-in-the-bag (Nacka), and Régéthermic system.

Legend:

17. Linear-arrangement kitchen with automats. For large output, there are appropriate appliances for steaming and baking.
18. Linear-arrangement kitchen with transport-equipment system. In the foreground: dish washing; soup, vegetable, and entrée vats; stove for general purposes and dietary foods; sauces and meats.
19. Three-tier carousel (Maison Tricault, Paris) of 2-meter diameter, with a tray slide.
 - 1d. Self-service three-tiered carousel
 - Below: 2 cold dishes, various salads, desserts (partly on ice)
 - Center: warm meals, 3 warm dishes, 2 grilled or fried dishes (with warming lamps above)
 - Above: sandwiches, pastry, etc.
 - 1e. Salad dressings, condiments, extra cutlery, etc.
 - 1f. Cash register
 2. Dishwaster (stacking area, 3 tanks, drying zone)
 - 2a. Soiled-dish conveyor belt
 3. Beverage self-service area
 - 5a. Portioning table for cold dishes and salads
 - 5b. Portioning table for desserts, sandwiches, etc.
 - 6/7. Warming and defrosting appliances
 - 6/7a. Portioning table for warm meats
 - 8a. Trolley storage
 11. Meal delivery from the central kitchen, access to the supply and auxiliary rooms
 - 11a. Storage cupboards for cold goods and other goods delivered from the central kitchen

By FRANK MEMOLI

CORE LOCATION

Central (Interior)

This location has a number of advantages. It allows all window space to be utilized as rentable office space and depending upon the configuration of the building plan will permit offices of varying depths to receive natural light. The central location is also extremely convenient in terms of access and in some cases may be equidistant for all sides. This simplifies area division and provides good flexibility of tenant distribution in the same way. Horizontal utility runs may also be relatively equidistant from the core. Combined with a square building plan, bearing exterior, and core walls this location permits a floor plan free of columns and thus totally flexible for office layout.

While this core location has definite advantages, it also has some drawbacks. One disadvantage is that the central interior location limits the depth of offices in the midzone of each floor, thus affecting the element of flexibility in office layout. Another floor-area-consuming characteristic of this core is that it requires an access corridor around its perimeter.

Off-Center (Interior)

Like the central-interior core, the off-center interior core permits all window or building perimeter space to be used for offices. However, it presents somewhat more flexibility in maximum depth and arrangement of spaces. This can be particularly desirable where large open spaces such as secretarial or clerical pools are required. It also affords the opportunity of developing small secluded spaces in the relatively narrow portion of the floor plan where the core is closest to the exterior walls.

This core location may present some problems of access. Because it is off-center, it is somewhat remote and thus less convenient to the far sides and corners of the building. If there is multiple-tenant occupancy on any given floor, a long access corridor will be required as will be a perimeter corridor around the core itself. The off-center location may also lessen flexibility of tenant distribution.

Split (Interior)

The principal advantage of a split core is that it virtually eliminates the need for a peripheral corridor on the core. Access to this core is from the area between its split elements and not from the area around its edges. This permits more flexibility of floor-area division, leaving even the area immediately adjacent to the core available for office space. Depending on the width of the access space in the center of the core, this space may be put to different uses on different floors. At the ground, or entry, level this area can become a lobby, while on floors where elevators do not stop this space can be used for additional office space.

Exterior

Unlike the three interior core locations discussed, the primary advantage of an exterior core arrangement is that it leaves the entire floor area of the building available for tenant use. In addition, the core does not complicate the floor plan either functionally or structurally. With this type of arrangement, maximum flexibility is achieved with respect to tenant distribution, office depth, and layout. Since the core creates a "dead wall" or portion thereof, it may be used as a buffer between the building and an adjoining property which may have objectionable characteristics. Location on the outside of the building also permits the core to act as a point of transition between one building and another of possibly different scale.

Some problems are also created by placing the core on the outside of a building. The primary drawback is that, in the case of multi-tenant occupancy, the core requires a long access corridor lessening flexibility of tenant distribution. In addition, the core occupies desirable window space so that the offices immediately adjacent to the core may not receive any natural light.

GENERAL PRINCIPLES

Work Flow

The relationship of individuals, as determined by operating procedures, must be the governing factor in any layout. The development of a layout which conforms to and complements the predominant work flow requirements of an office is perhaps the most important phase of space planning. By the systematic study of the operations, processes, and procedures involved in individual (or group) tasks, the planner can assist management by providing work station patterns which ensure a smooth, straight-line flow of work. It should be understood that space planning does not conflict with or overlap the field of methods and systems analysis. The role of the space planner is to gain a knowledge of the functions, as developed, and to translate them into the best space layout possible within the limitations imposed by building characteristics, fiscal allotments, etc.

Straight-Line Principle In a well-planned office, paper goes from one desk to another with the least amount of handling, traveling, and delay. Work should progress in a series of straight lines with a general forward movement, avoiding criss-cross motion and backward flow. When the layout is being developed, the flow pattern can be traced from desk to desk. Caution must be exercised, however, since the straight-line work principle cannot be adapted to all activities, particularly those headquarter or departmental offices whose staff activities do not lend themselves to assembly-line processing.

Guide for Space Planning & Layout, General Services Administration, Public Buildings Service, Washington, D.C.

Work Stations

All work stations, whether in a private office or in open space, are reduced to units of furniture and equipment. See Fig. 1 for the work stations most frequently used. The basic unit of work stations are desks and therefore require the most consideration. The following general rules are applicable in positioning desks:

1. Desks should face the same direction unless there is a compelling functional reason to do otherwise. The use of this technique provides for straight work flow patterns, facilitates communications, and creates a neat and attractive appearance.

2. In open area, consideration should be given to placing desks in rows of two. This method will permit the use of bank-type partitions as a divider for those activities which require visual privacy while still obtaining maximum utilization.

3. Desks should be spaced at a distance of 6 ft from the front of a desk to the desk behind it. This distance should be increased to 7 ft when desks are in rows of two, ingress and egress is confined to one side of the aisle, or in instances where more than two desks side by side cannot be avoided.

4. In private offices the desk should be positioned to afford the occupant a view of the door.

5. In open work areas the supervisor should be located adjacent to the receptionist or secretary. Access to supervisory work stations should not be through the work area.

6. Desks of employees having considerable visitor contact should be located near the office entrance. Conversely, desks of employees doing classified work should be away from entrances.

"Executive Core" Concept

Most new building designs produce a block-type structure which is well lighted and air conditioned, and which is divided by a few access corridors radiating from a central service core. This type of construction permits development of space plans based on the "Executive Core" concept. This concept, or technique, places all or a majority of the private offices in the core area and allocates space along the building perimeter for others. It has proved very satisfactory in many cases where it has been used and has potential in most new buildings in which large, or relatively large, groups of "lower echelon" employees will be housed.

This concept arises from the premise that employees performing routine tasks which keep them at their desks almost the entire work day require the psychological advantages of window space. On the other hand, supervisors and executives are frequently called upon to leave their offices for meetings, supervisory tours, etc., and interior offices, if properly designed and decorated, are completely acceptable for them. Also, the occupants of private offices generally receive the greatest number of visitors; in fact, the need to receive many visitors is perhaps the justification most frequently given for private offices. The location

of private offices in the core facilitates the handling of visitors and keeps them from the general work areas.

Other Planning Considerations

The application of the following considerations will assist the space planner to attain functional effectiveness in the final layout:

1. Employees performing close work should be in the best-lighted areas. Glaring surfaces which affect vision should be identified and corrected.
2. Clothes lockers in an office layout are out of date and wasteful. Large rooms or open areas should be provided with hanging space for coats and shelves for hats, packages, and other material. Space not suitable for work stations should be used whenever possible.
3. Heavy equipment generally should be placed against walls or columns in order to avoid floor overloading.
4. Be safety conscious. Do not obstruct exits, corridors, or stairways. Comply with fire safety codes governing aisles, exits, etc.
5. Where frequent interviews with the general public are required, as in personnel offices, the use of interview cubicles should be considered. Such cubicles need only be large enough for the interviewer, the applicant, and a small desk or table.
6. In operations which require employees to work away from their office, with only infrequent visits there to file reports, etc., consideration should be given to assigning two or more employees to each desk. Other considerations include the provision of 45-in. desks and the use of common work tables, with the assignment of file cabinet drawers to each employee in which to keep papers, etc.

Private Offices

The private office is the most controversial problem facing the space planner. The assignment of private offices and the type of partitioning to be used are issues to be settled by top management acting on the advice and recommendations of the space planner. Private offices should be assigned primarily for functional reasons, i.e., nature of work, visitor traffic, or for security reasons. When private offices are provided, they should be only large enough for the occupant to conduct his normal business with a reasonable degree of dignity (Fig. 2). The following are some of the factors requiring consideration prior to making the assignment:

Classification Grade The necessity for a private office cannot be directly related to the classification grade of the employee.

Supervisors in Open Space Supervisors who are working with their employees, rather than planning for them, should generally be in the same room or open space with them. The supervisor may be separated from the balance of his section by a distance of several feet which permits a degree of privacy.

Prestige A frequent justification for a private office is to impress visiting representatives of industry, and the general public, with the importance or dignity of the official being contacted. Recent studies of office planning in private industry tend to refute such a position. They show many highly paid employees housed in attractive open space. Moderately sized private offices are provided only for upper-echelon officials. The offices of many top executives of large, nationally known companies are less than 250 sq ft each. The provision of a private office, or too large a private office, for a Gov-

ernment official may give the taxpayers an adverse impression.

Security Requirements The space planner hears many reasons why people in Government need places where confidential discussions can be held and a variety of suggestions as to how this should be accomplished. The private office is the most popular, if not always the most practical, solution. The Federal establishment undoubtedly has a greater problem in this respect than many branches of business.

In addition to the security requirements, the Government is faced with privacy situations involving investigative agencies and other activities which have occasion to inquire into the most confidential aspects of individuals' personal lives and the operations of business concerns. There is no question as to these persons' entitlement to reasonable privacy regardless of whether they are summoned to the office, appear voluntarily to render assistance, or avail themselves of services offered by the agency. There are alternatives, however, in determining the methods to be used to satisfy the various requirements.

Sizes of Private Offices It is desirable that private offices be a minimum of 100 sq ft and a maximum of 300 sq ft each in size, depending upon the requirements of the occupant. See sketches of most widely used private offices. Only in cases where it is necessary for the occupant to meet with delegations of 10 or more people at least once a day should the size approach 300 sq ft. For the average Government function, the private office should not exceed 200 sq ft.

Semiprivate Offices

The semiprivate office is a room, ranging in size from 150 to 400 sq ft, occupied by two or more individuals. These offices can be enclosed by ceiling-high, three-quarter-high, or bank-type partitions. Examples of semiprivate offices are shown. Because of the loss of flexibility introduced by the use of the partitions required to enclose these offices, the same rigid review given private offices should be employed. Generally, the need to house members of a work team or other groups of employees assigned to a common task is an acceptable justification for semiprivate accommodations.

General or Open Space

The following paragraphs describe some of the factors affecting good office layout in general or open space:

General "General office space" refers to an open area occupied by a number of employees, supervisors, furnishings, equipment, and circulation area. Large open areas permit flexibility and effective utilization, aid office communications, provide better light and ventilation, reduce space requirements, make possible better flow of work, simplify supervision, and eliminate partition costs. In many cases, however, open-space housing for more than 50 persons should be subdivided either by use of file cabinets, shelving, railing, or low bank-type partitions.

Open-Area Work Stations The space allocated to these work stations is based on the furniture and equipment necessary to perform the work assigned as well as on circulation area. The space assigned to any specific work station may be increased due to special furniture and equipment requirements associated with the particular position.

Circulation

This is the area required to conveniently permit ingress and egress to work stations. The size of an aisle should be governed by the amount of traffic it bears. The following standards with regard to internal circulation will be applied in space planning surveys:

1. Aisles leading to main exits from areas which carry substantial traffic (main aisles) should be 60 in. wide.
2. Aisles which carry a moderate amount of traffic (intermediate aisles) should be 48 in. wide.
3. Aisles between rows of desks (secondary aisles) should be approximately 36 in. wide.

Conference Requirements

Conferences, meetings, and assemblies are an important part of Government operations. Since there is no established standard suggesting the number of conference rooms based on the number of people, the needs will vary widely among agencies or agency components, depending largely on the nature of their work. Whenever possible, the establishment of conference rooms should be based on need established from past records and experience, rather than on anticipated needs. Unnecessary conference space is often allowed because planning is not based on such records of demonstrated need. The space planner should always evaluate the utilization of existing conference rooms before recommending others (Fig. 3).

Conference Space in Private Offices vs. the Conference Room Conferences are best conducted in space designed for that purpose. Conference space should not be provided in private offices. In lieu of large offices, it is desirable to provide a conference room adjoining the office of a top official who holds a large number of conferences and nearby conference rooms for officials with more limited requirements. Separate conference rooms permit maximum utilization through scheduling at an appropriate level of management. Where feasible, training and conference requirements should be pooled and conference space used as auxiliary office area for visitors.

Location of Conference Rooms The conference room should be centrally located to the users. Interior space, which is not the most desirable for office purposes, is well suited for conference use. This location eliminates outside distraction and the need for window coverings during visual presentations. Access to conference rooms should be through corridors or through reception areas.

Sizes of Conference Rooms Conference rooms should be designed to accommodate average but not maximum attendance. Extra chairs can be used to achieve additional seating. See illustrations of preferred layout of conference rooms of various sizes.

Reception Areas and Visitor Control

Visitors receive their first impression of an organization from the decor and layout of the reception area. It should be attractive, neat, businesslike, and above all, adequate to accommodate normal visitor traffic. An allowance of 10 sq ft for each visitor to be served may be used for space allocation. For example, if space is required for a total of five visitors at any given time, a total of 50 sq ft should be used in planning the space. Size, decor, and equipment will depend largely on the type and volume of visitor traffic; thus special

planning will be required to meet specific needs. The receptionist should be placed so as to command a clear view of those entering and be easily accessible to visitors.

Storage Space

Office space should not be used for bulk storage. Only working inventories of office supplies and other materials should be maintained in offices, preferably in standard supply cabinets. Secondary space, such as basement areas, should be used to locate supply operations.

Special Requirements

"Special requirements" refers to space other than that required for furniture and equipment usually found in office operations and which is essential to the work of the agencies. The space planner must identify these special requirements in the early stages of the space planning.

Interim Space Allowances Table 1 gives allowances to be used by The General Services Administration in space planning for agencies, or elements thereof, which do not have Occupancy Guides, including agency headquarters activities. These allowances are canceled immediately upon publication of the appropriate Occupancy Guide.

OFFICE LAYOUT BY FUNCTION

The office operation is like a large machine which needs to have all of its parts synchronized and moving smoothly. Each office function must mesh smoothly with the others with a minimum of friction.

The office machine's source of power is information, and it is the purpose of good office layout design to permit this information to flow smoothly, avoiding unnecessary turns and traps. There is certainly no one office layout that will fit all companies, any more than there is an all-purpose machine, but there are some reasonably good principles of layout by function that could be applied to any office situation.

Six Basic Office Functions

If you were to make a list of the typical office functions, you would find it quite a long one. Every office needs management, communications, filing, billing, payments, payroll, purchasing, and accounting. Other functions are added according to the purpose of the business,

such as production, production engineering, quality control, shipping and receiving, cost accounting, industrial engineering, data processing, inventory, etc.

However, all office functions can be cataloged into one of these six groups:

1. Management
2. Finance
3. Sales
4. General services
5. Technical services
6. Production

Here are some pointers for placing these groups in the best office layout position to permit smooth operation.

The Management Group The top management group is usually arranged together, often in a sort of chain of command. They will be reasonably isolated from general office traffic and casual interruptions. They are frequently around the edge of the office, but they may also be in the center. The top official is perhaps the chairman of the board or the president, and he naturally will have the largest and best appointed office. The top executives need more space not only for prestige but because they have more than the usual amount of visitors and meetings. If a conference room is used, the size of the individual offices can be reduced somewhat. There is a trend away from the overabundant office for the top executives, undoubtedly encouraged by the high cost of office space rental. The newer designed, space-saving furniture, however, makes the reduced space practical from an efficiency standpoint. It is not unusual in the newer offices to find the top management men in offices about 12 by 15 ft in size.

The Financial Group Although the financial executives have responsibilities that extend into the general office and involve a considerable percentage of the clerical force, the executives need not be on the spot. Supervisors can run the show with little more connection to the boss than through intercoms or interoffice mail.

It is probably more important to put the accounting function near where it picks up the orders from the sales department. The accounting functions usually line up according to the system procedure, going in a straight line through such activities as credit checks, order processing, inventory control billing, and finally accounts receivable.

The purchasing department has a lot of contact with vendors, so it should be near the entrance or reception room to avoid excessive traffic. Part of purchasing has to be tied to the accounting function through the handling of requisitions, shipping notices, and vendors' invoices.

The personnel department is usually close to the reception area so that they can interview job applicants and other callers without general disruption of the office area.

The data processing activity usually comes at the end of the line, but it should be out of the traffic swirl and in a spot where the noise can be confined.

The Sales Group Every firm has some sort of a sales function which starts the activity of the company. For this reason there is a considerable amount of communication between it and all the other functions of the office. The sales group frequently has visitors and needs a lot of space for catalogs and specification files, so that each person there probably has a little more than the average amount of floor space. Pricing, estimating, and correspondence are large functions in the sales group. Many

sales groups need a conference room or an all-purpose room that can be used for training, meetings, demonstrations, and conferences with the engineering and product development group.

The General Office Group This is the group that provides general services for all of the other functions, such as central files, stenographic service, library, mail handling, duplicating, and general communications.

The reference functions like central files, the library, and the stenographic pool are normally in the center of all the other functions in the office. The mail handling is at either end of the office work flow. Duplicating services are normally isolated because of the noise and fumes, and may be near the function that calls most frequently for this service, such as shipping and receiving rooms.

The telephone switchboard is part of the job of the receptionist, and is naturally in the reception area. In a more complicated communications setup it might be in a center by itself, convenient to the other office activities.

Technical Service Group Technical services such as the engineering, drafting, and design people are normally located near the activities they assist, such as manufacturing, sales, and production. When they deal with production and systems work they are frequently out in the plant.

The Production Group The production group is usually in a second office, set up out in the production plant. It is just as important to the business as the general offices and should have the same amount of considerations, dignities, and facilities. This is not always the case, unfortunately, but where it has been the policy to put this office group on a par with the general offices, an improvement in work and general morale has been accomplished.

In any large-scale planning, other factors besides available space will naturally influence the decision for the final placing of any particular department. The shipping and receiving departments, for example, could hardly be placed on the top floor even though their space requirements would fit perfectly into a given area on the top floor.

Study the Organization Chart

The arrangement of the office functions will actually be a projection of the organization chart of the firm, located with respect for the flow of work and the physical requirements of each department.

The organization chart will show the departments and sections which make up the firm, like the executive, offices, sales, accounting, engineering, production, research, and purchasing. The chart will also give a clue to the interrelationship of the departments.

Relatively minor activities are better placed around the major office activities rather than integrated with them. When more space is needed, the major activities can be expanded with less disruption simply by moving a minor activity over a desk or two.

Each department and division has a good reason for being in one location rather than another. Here are ten guides for determining what that location should be. When the department is properly assigned to a major area, minor changes can be made later without an upheaval in the basic pattern. Some departments will naturally qualify in several of these guides, and then it will be a matter of choosing the locations which seem to offer the best compromise.

OFFICES, GENERAL

Space

1. Convenience to the Public Those departments having the greatest number of visitors should be located so that the visitors have a short, direct, and convenient route from the main entrance to the department sought. The sales, purchasing, and employment or personnel departments usually have the most visitors. Convenient access is not only enjoyed by the visitors but it offers the least disturbance to the work of employees.

2. Flow of Work Departments having the closest working connections should be placed closest together. When this is done, the work flows with a minimum waste of time between operations. Sales and advertising departments normally work together; so do the sales and credit departments, cost and payroll departments. When they are too far apart, unnecessary walking time is increased or the telephone switchboard or intercoms are overworked.

3. Equipment Used Some departmental operations require the use of special equipment requiring extensive wiring, plumbing, or ventilation equipment. Moving departments of this type requires expensive alterations. Obviously, two such departments should not be located together because of the difficulty of later expansion.

Some sections of a department may use noisy equipment. They may use teletypes, tabulating equipment, reproduction equipment, and similar specialized equipment. Typing and stenographic sections, because of their concentration, will produce a higher noise level than a similar number of machines scattered throughout the area. To minimize disturbance to the rest of the employees, these sections are commonly segregated into sound-treated rooms.

4. Centralized Functions Sections and facilities that serve the entire office should be centrally located and easily accessible to all who use them. Correspondence and stenographic pools, central files, cost accounting, and tabulating are examples. Of course, rest rooms, water fountains, and supply cabinets should be provided in sufficient numbers and conveniently located.

5. Confidential Areas Certain functions of a business may be of a confidential nature that requires them to be isolated from others in the office and from the general public. Central files, the paymaster, the controller, and legal offices are examples.

6. Conference Rooms Conference and training rooms should be reasonably near those departments that use them the most. If the office is air conditioned, the room can be in the interior of the space to eliminate the distraction of windows and to provide more wall display area.

7. Freight Elevators Departments receiving and delivering large quantities of materials should be located near the freight area for ease of handling, less time and labor, and less distraction of other workers. Mail, stockroom, and machine departments are in this category.

8. Shipping Dock Shipping and receiving activities and mail rooms should obviously be near the point of entrance and exit of material.

9. Service Facilities Eating, medical, and lounge facilities are generally on the lower floors to reduce elevator traffic. The number and type of employees in a particular department might be considered in locating it near these facilities.

10. Passenger Elevators When an office occupies more than one floor, elevator service will be more effective when the departments with large clerical forces are on the lower floors.

The fundamental unit (module) for office space planning is the *individual worker*, seated at his or her desk or work station. The space allowance assigned to each worker can be either liberal or economical depending upon space limitations or the kind of atmosphere desired in the office.

In larger offices where there are many routine jobs, space standards tend to be economical. Where the work is specialized, where there are many visitors, or where high morale is promoted, space assignment is apt to be more generous. Larger firms tend to be more economical than smaller ones, for the extra space means extra rental costs or more buildings. Smaller firms have fewer routing operations and tend to have more generous space allowances.

In the general office area, allotment of 100 sq ft per clerical worker is generally considered a liberal standard; 65 sq ft is an economical standard. Eighty square feet would be a reasonable average.

FIVE GUIDES FOR SPACE ALLOWANCES

Good space utilization does not necessarily mean allocating the least possible working space per person. On the contrary, too little working space may reduce the worker's efficiency and waste many times the savings made by any reduction in the square-foot rental costs. Good space utilization, in its broad meaning, allots more space to those positions whose activity justifies it, and reduces the space where there is a surplus.

There is no accurate scale of space allowances which will make layout planning automatic. We can give you here, however, some guidelines which have been established from a large number of surveys made of offices, both commercial and governmental. These suggestions will help you make a broad estimate of your space requirements or will serve as a check against your own utilization of space.

We can break down the types of space required in the typical office into five categories as follows:

1. Office space
2. File space
3. Special equipment
4. Storage space
5. Special rooms

Let's discuss these five space categories separately.

Office Space Allowance

The following typical allowances include space for departmental aisles, space to move about, space for occasional visitors and consultation, rest rooms, fountains, special files, general office equipment, bookcases, and coat racks. It does not include main aisles, corridors, or the space covered by the other four space categories.

	Square feet
Top executive	400-800
Junior executives	100-200
Supervisors	80-100
Operator at 60 in. desk	65
Operator at 55 in. desk	60
Operator at 50 in. desk	45

Operators are assumed to be at desks side by side, two in a row. Add space for file and side chair if needed.

The use of L-shaped furniture for work stations will give more *surface* room than the standard desks, but the *floor space* will be roughly equivalent when the width is the same as desks above.

File Space Allowance

The actual space taken up by a file cabinet and its open drawer is easily measured. It is difficult to estimate how much should be added to these measurements for working area until decisions are made on arrangement of the filing area.

In general, each open file cabinet will require the following space allowance without consideration of any working area in front of the open drawer:

	Square feet
Standard letter file	6
Standard legal file	7
Side-opening letter file	6½
Side-opening legal file	7½

Special Equipment Allowance

Certain special types of office machines require more space than normally allowed in an estimate based on the average clerk or typist position. Any space taken up by the following equipment and their operators should be added to that considered for the regular office space.

1. Tabulating equipment
2. Duplicating equipment
3. Telephone switchboard
4. Teletype equipment
5. Time clock space
6. Other special equipment

Storage Space Allowance

Storage requirements depend on the nature of the firm's work, its age, and the inclination of the administration to retain records. Here are some storage space requirements which should be considered:

1. Vaults
2. Stockrooms
3. Transfer files
4. Shelving
5. Janitor supplies and equipment
6. Stock rooms
7. Coat rooms

Special Rooms Allowance

Depending on the type of business, offices will require rooms of a size matched to their use. These will include:

1. Reception room
2. Waiting room
3. Interviewing room
4. Examination room
5. Conference room
6. Exhibit room
7. Medical room
8. Lunchroom
9. Employee lounge
10. Rest room
11. Mail room

The more common rooms will have the following typical space allotments, based on their use by 15 people.

	Square feet
Reception room	400
Waiting or interviewing room	200
Conference room	500

Add approximately 10 sq ft for each additional person to be provided for.

OFFICES, GENERAL

Planning

Fig. 8 Office planning: layouts for private offices.

Office layout is often based upon a module derived from standard furniture and equipment and the necessary clearances. For large general offices, the planning unit or module is based upon one desk and chair and is thus about 5 by 6 ft. Since this dimension is also satisfactory for aisles between rows of desks the module can be used to form a regular grid for the planning of large office areas (Fig. 9).

In the layout of private offices the controlling factors are the minimum practical office layout with the wall and window design. A planning module of 4 to 5 ft works reasonably well for this purpose. With this module the smallest office (2 modules) would be 8 to 10 ft wide, and a convenient range of office sizes is provided in increments of one module (Fig. 10). If the exterior wall consists of continuous windows, one module in width, then the office widths are limited to even modules. If windows alternate with solid walls, then office widths do not have to be in even modules but may vary widely (Fig. 11). This type of wall

design permits greater flexibility in office layout at the expense of less natural light in the offices.

The planning module and the exterior wall module must be reconciled with the structural module or column bay. If all these modules coincide, then the wall or window units adjacent to the column must be smaller than the intermediate units (Fig. 12a). If the wall units are kept uniform in size, then the planning module is interrupted by the column width (Fig. 12b). If the columns are set inside the walls, they do not interfere with the wall module but they create a serious limitation on the layout of private offices (Fig. 12c). If the columns are set outside the walls, then the planning module and the wall module are not affected by them (Fig. 12d).

Column spacing most frequently used in multistory steel-framed office buildings is around 25 ft, center to center. Recent trend is toward larger spacing; 30 to 35 ft is not uncommon. Flexibility of interior space is so important in office building design that the extra cost of clear span framing with the elimination of all interior columns is sometimes considered worthwhile; clear spans of 60 to 70 ft have been used.

OFFICES, GENERAL

Planning; Landscaping

Efficiency of an office building design is measured by the ratio of rentable space to total space. Average efficiency is about 70 percent; maximum possible is about 85 percent. The non-rentable space consists of the elevators, stairs, and toilets and their associated lobbies, corridors, pipe and duct shafts, and janitor's closets. These facilities are usually planned in a compact unit called the service core. For preliminary assumptions, the number of elevators required may be estimated on the basis of one elevator per 25,000 sq ft of rentable area. Elevator lobbies should be 6 to 9 ft wide if elevators are on one side only; 10 to 12 ft if elevators are on both sides. Corridors are usually 5 to 6 ft wide (Fig. 13), wider if very long, narrower if very short.

Fig. 13 Corridor width based on requirements of human figures.

Since the floor space within 25 to 30 ft from the exterior wall brings premium rentals, office buildings (site or zoning consideration aside) tend to assume a slablike shape, 60 to 70 ft wide by 150 ft or more long, with the service core in the center (Fig. 14). For greater flexibility in the

Fig. 14 Typical slab plan with service core at center.

Fig. 15 Maximum flexibility of rental area achieved by use of clear-span framing and separate service tower.

rental space, the service core may be moved completely outside the office space. When this scheme is combined with clear span framing, the ultimate in flexibility is achieved (Fig. 15).

Floor-to-floor heights are usually about 12 ft, ranging from 11 to 14 ft. Finished ceiling heights are generally about 8 to 8½ ft. The space above the ceiling is required for ducts and recessed lighting. In order to avoid excessive depths in this utility space, girders are sometimes designed with openings in the web to permit the passage of ducts.

OFFICE LANDSCAPING*

A number of large U.S. corporations have been experimenting with an open planning system known in the space-planning and design profession as "office landscaping." This concept of planning originated in West Germany and has been used extensively in European office operations. It is intended to create an open, flexible layout by grouping personnel and their work stations in accordance with group communications and with interdepartmental work flow and relationships.

The proponents of the landscaping concept maintain that office planning should not be based upon the traditional organization chart of command structure, but rather on the grouping of personnel in open space along the lines of interpersonal relationships and group communications. When this concept is applied in its most literal form, it means the elimination of private offices, with no distinction made between "management"

personnel and "general office" personnel. The offices are designed with no fixed walls or partitions. The entire floor space is treated as open space with movable screens, plants, and furniture arrangements utilized to create functional work groups. With the elimination of fixed walls or partitions, a maximum degree of long-term flexibility can be achieved. It should be recognized, however, that in a totally open floor space without walls or partitions, provision for telephone and electrical outlets must be made either through a complex underfloor electrical duct system or through a system that affords the opportunity to drop telephone and electric lines from the ceiling to the work stations below. It should also be recognized that in this type of open operation, factors such as lighting, noise control, and air conditioning will present technical problems that must be dealt with and solved in order to insure a physical environment conducive to a satisfactory work situation.

While presenting technical problems to the office planner, these problems can be solved with careful study and engineering know-how within the existing technology. It is the opinion of the author that although the office landscaping concept offers many advantages, it may also create many new problems unless it is applied after a very thorough study of all factors related to overall office environment.

CLEARANCES FOR GENERAL OFFICES

Fig. 3 Standard clearances for legal and letter-sized files.

Insurance company facilities can be divided into two categories:

1. The home office
2. The branch regional office

In general, it has been found that insurance companies would rather rent or lease office space than own their own building.

HOME OFFICE

Unlike the branch regional office, the home office does not have insurance agents. Home office operations are mainly concerned with clerical and secretarial work necessary to maintain close operational contact with the branch offices. The home office is involved with (1) the processing of policies, (2) supplying standard company forms and policies, (3) keeping both active and dead records on policyholders and files on issuance and payments, and (4) data processing. A home office needs several more or less standard facilities, and it is with these that this section is concerned.

Auditorium/Agent Training Area

This space is used mainly for insurance agent training purposes, but on occasions it can be used for regional agent conferences. It should have a stage with facilities for a screen for training movies and slides. It should be flexible enough to accommodate two or more small groups with maximum separation and a large group of 200 to 300 persons.

Mail Room

The mail is handled through a central mail area with branch mail areas in each major department of the home office. Main flow of mail goes to two main departments:

1. Issuance department
2. Claims department

Accounting Area

This area deals with agent commissions, personnel payroll, clerical and secretarial work, and photostat copying. Areas should be provided for the director of accounting and head of the secretarial staff. A small safe is required for petty cash and various essential documents. A large fireproof safe is required for storage of all major documents, such as dead policies, etc. This area should also have a storage area for stationery and standard forms pertinent to this department.

Issuance Area

In this area are made up the different types of

insurance policies that are to be issued by the company as standard life insurance policy forms. Areas should be provided for the director of issuance and head of the secretarial staff. A storage area for stationery is required.

Underwriting Area

In this area, policies are checked in order to determine security risks of prospective insureds. An office for the director of underwriting should be provided. This area also has space for filing cabinets to hold dead and live files.

Group Sales Insurance Area

In this area, reissuance and group sales insurance is handled. An office for the director of group sales insurance should be provided, along with storage and filing space.

Claims Area

This area handles all insurance claims from all branch regional offices. This area should also have an office for the director of claims. An area should be provided for active and dead files of policyholders.

Agency Area

In this area, all controls of operational aspects and dissemination of information to branch regional offices occurs. All branch regional office policies are handled here. A separate filing cabinet for each branch office agency is required.

Policyholders' Service Area

This area handles all weekly premiums and monthly debit payments from policyholders. An active payment files and records area is required. A director's office and storage area are also required.

Data Processing Area

All data processing and tabulation is done in this area. It should be soundproofed and requires special air-conditioning. All data processing machinery should be accessible from all sides, and false floors are recommended in which to house the cables. A storage area for forms pertinent to this area is required.

Auditing Area

This area should be close to the policyholders' service area and the underwriting area because

new policies are not issued until policyholders have complied with all requirements. This area also controls the bookkeeping and payment records for individual policyholders. There should be a director's office and an office for the head of the secretarial staff. A storage area is required.

Printing Area

This area handles the printing of all company stationery, letterheads, forms, etc. A generous storage area is required, both for small items and bulk storage.

Reception Area

This area should be adjacent to the executive offices and should contain the master switchboard for all incoming and outgoing calls. A secretary is needed here along with the PBX/receptionist. Enough area should be allowed to seat about ten people.

Executive Office Areas

A unique and handsome office is required for the chairman of the board. Other offices are required for a president, for senior vice-presidents, and for junior vice-presidents. The design of these offices is usually determined, as to size and furnishings, by requirements set forth by the individual companies. Private rest areas may be provided but are not necessary. A conference room is required and should accommodate at least 20 people.

Main Storage Area

Should be of sufficient size to handle all standard policies, stationery, agent brochures, pamphlets, etc.

BRANCH REGIONAL OFFICE

The branch regional office is the home base for the company's regional insurance agents. The public does not usually enter the branch. Payments are all handled by check. There are two types of branch regional offices:

1. General agent type
2. Manager type

The general agent type is designed by the private insurance agent and the builder. The manager type follows a standard design set by the home office. Basically, a central area is required for secretarial and clerical work. This area should not be accessible to the agents. Agent offices, conference room, executive offices, and library should surround the central area for ease of operation.

The eight basic elements of a medical office are:

1. Receptionist—control station—business office
2. Waiting room
3. Consultation room
4. Examination and treatment room
5. Laboratory including EKG and BMR
6. X-ray
7. Utility and service areas
8. Toilet

A medical practice facility can have no fixed, ideal plan. First, no two individuals or groups of individuals think alike or work alike. Second, the physical and geographical limitations which characterize a medical practice facility, whether for a new building, a remodeled building, or rental space, do not permit the adoption of any single plan. Each facility must be custom-made to express the individuality and to satisfy the working habits of those who will use it.

The eight basic elements found in nearly all medical offices can be thought of as the "building blocks." While these eight elements may change in size and shape depending on methods of operation, they are always integrated in the medical practice facility, or their counterpart is conveniently available (Fig. 1).

In the following pages will be found draw-

A Planning Guide for Physicians' Medical Facilities, edited by the American Medical Association and published through a grant made by the Sears-Roebuck Foundation.

ings and explanations of each of the eight elements, and further examples of how they can be combined and expanded.

1. RECEPTION AND BUSINESS OFFICE

The receptionist, who, in the small medical practice facility is also the doctor's assistant, the bookkeeper, and the bill collector, is the hub around which the office revolves. She should be so placed that she can keep an eye on all the workings of the office. She should see and acknowledge the arrival of the patient and must follow the progress of the doctor so that the patient flow has proper direction. If she discusses bills and appointments, the space should be large enough for others besides herself, and private enough that her conversations are not generally overheard.

For the larger office the functions mentioned above may be split among two, three or even more persons. The receptionist still should be able to see the entrance and the waiting room. If she is too far removed to watch the progress of the doctor she has to be informed by the nurse assistant of this progress so she can keep the flow of patients coming.

If there is a separate business manager-bookkeeper, a private space should be provided for working on records, and discussing bills with patients. It is advisable this office be located so that it is accessible to outgoing patients. The exit from this office should permit patients to leave without backtracking, or

going through the waiting room. Proper relationship to the entrance will also assist in the control of deliveries to the office (Fig. 2).

2. RECEPTION—WAITING ROOM

The patients receive their first impression from the waiting room. Its appearance may indicate the type of care they can expect to receive. A wait in a crowded, out-of-date room can depress and disgruntle even the best and steadiest of patients.

The chairs, tables, and lamps should be adequate in number and well spaced so as to make reading possible and to give the patients a feeling of freedom. The patient load provides the only criterion for the number of chairs you must provide. If the schedule is always well maintained, the waiting area need only be a minimum. If the doctor is burdened with emergency calls and extended house or hospital calls, then the waiting room should be more ample.

Needless to say, some educated thought should be given to decoration: the walls, upholstery, pictures, and drapes. Tasteful, harmonizing colors which are cheery rather than drab are desirable. The overall effect should be homelike and restful.

The waiting room preferably should permit a view of the outside and, if possible, the view should be a pleasing one. Flowers, trees, or distance are the best, but when this is impossible an interesting view of people and activity is the second choice (Fig. 3).

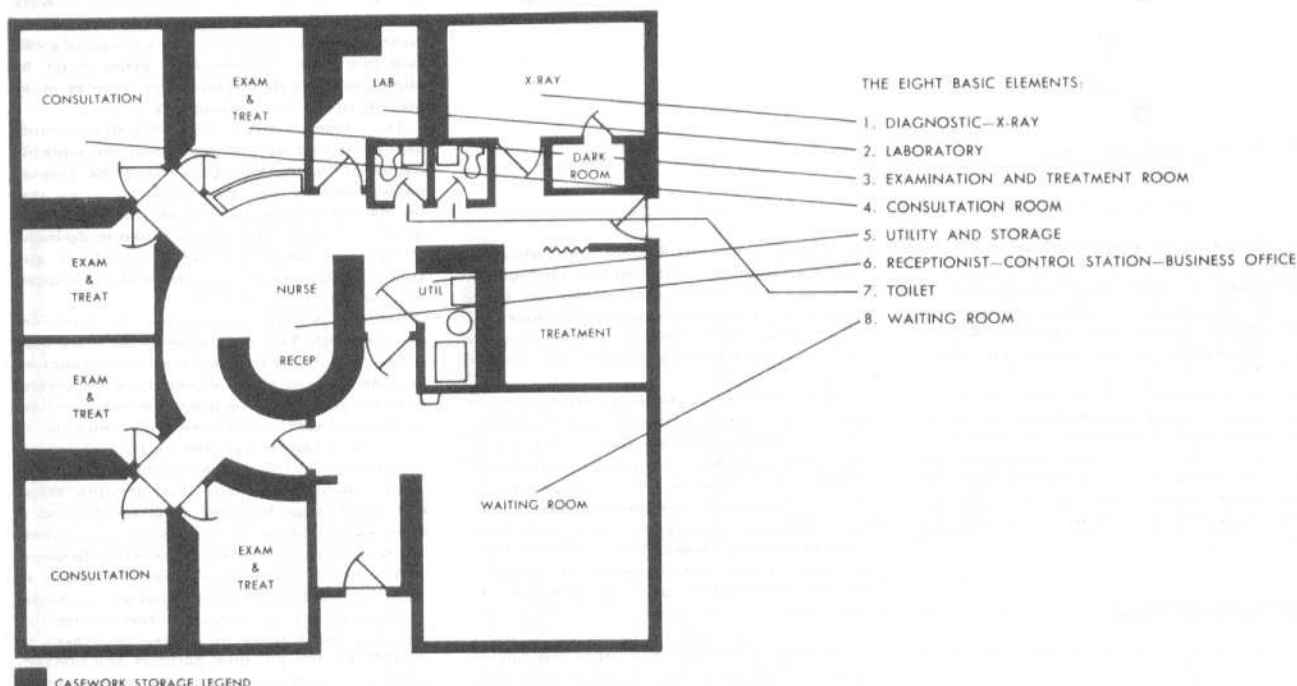

Fig. 1

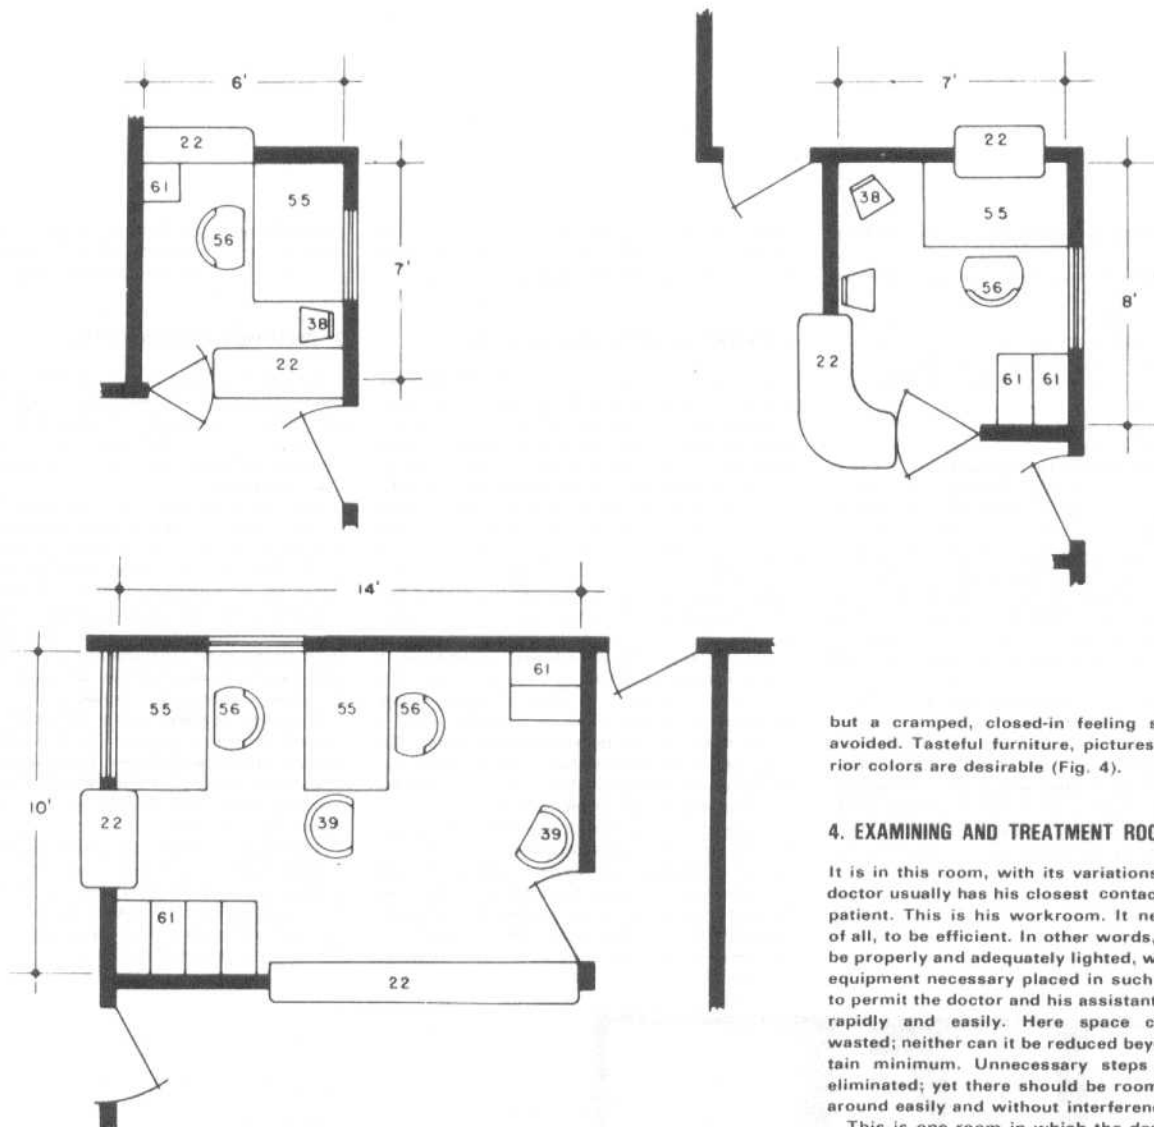

Fig. 2 Reception and business office.

The waiting room should be removed from the actual office activity. It should not be a thoroughfare for traffic, nor should it be an office for the discussion of bills and appointments between the receptionist or office manager and patients. If one enters the office directly from out-of-doors, it is well to have a lobby to prevent drafts. If the business office opens on the lobby, it may well serve to receive the incomer and to determine his business. This, in turn, allows some to be directed to the waiting room and others to be taken directly to the doctor without incurring hurt feelings and arguments from patients in the waiting room.

3. CONSULTATION ROOM

This space is generally the stopping point, at some time, for all patients passing through the office. The patient is usually directed there first for a discussion of symptoms and progress and for simple examinations. He is then sent to an

examination or treatment room, from which he may return to the consultation room for further discussion and prescription. However, there seems to be a trend to simplify and speed up this procedure, in a majority of instances, by concentrating the entire patient visit to the examination room.

This enables the physician to utilize another room for patient examination and treatment.

The theory that all space be used for examination and treatment or for purely professional use has merit. However, the average examining room is sparsely equipped and very impersonal. Patient discussions and diagnostic reviews are better handled in more comfortable and professional surroundings. A properly furnished consultation room can have a beneficial effect on both the patient and the physician. In addition physicians are called on by many professional detail men and other individuals in the medical field. Such contacts are better handled in a nicely furnished—but not elaborate—consultation room.

The consultation room need not be spacious,

but a cramped, closed-in feeling should be avoided. Tasteful furniture, pictures and interior colors are desirable (Fig. 4).

4. EXAMINING AND TREATMENT ROOM

It is in this room, with its variations, that the doctor usually has his closest contact with the patient. This is his workroom. It needs, first of all, to be efficient. In other words, it should be properly and adequately lighted, with all the equipment necessary placed in such a way as to permit the doctor and his assistants to work rapidly and easily. Here space cannot be wasted; neither can it be reduced beyond a certain minimum. Unnecessary steps must be eliminated; yet there should be room to move around easily and without interference.

This is one room in which the design must be determined by the needs and the working habits of the doctor. These must be investigated carefully and thoroughly in order that he may have what best meets his needs and desires. While he has been trained to do many things well, despite adverse conditions and scanty equipment, there is no need to handicap him on his home grounds.

Seldom is one examination or treatment room enough. Two rooms can often more than double the doctor's capacity, and some doctors have as many as eight. Where there are several rooms, patients can be prepared ahead of time by the assistants. Furthermore, a number of procedures can be handled by the assistants, on direction of the doctor, while he is putting his time to better use with other patients. When this practice is followed intelligently and it does not slip into an impersonal production line technique, it results in increased efficiency.

Where the examination-treatment room is used for most of the doctor-patient contacts, it is necessary to provide a few things not formerly found there. It is also necessary to provide for the patients' comfort and convenience. For the doctor, a desk or writing space, and perhaps a satisfactory chair for use during discussions with the patient, may be ample additions.

Fig. 3 Reception-waiting room.

For the patient, dressing facilities, cubicle, mirror, clothes hooks, slippers, chairs or low bench in or immediately adjacent to the examination-treatment room are a great convenience. A comfortable chair, magazines, and an ash tray are also advisable to ease the patients' waiting time when the doctor is delayed with some other patient (Fig. 5).

5. LABORATORY

This room varies from a few shelves, sink, sterilizer, etc., in the corner of the examination room to a complete laboratory in a separate room.

In the smaller office it is best combined with other uses for the saving of space and of steps. The nurses' workroom, the store room, the recovery room, and a spare examination room are all possible elements which can, under certain conditions, be combined with the lab-

oratory. The ideal, of course, is a room designed for specific laboratory procedures with adequate equipment and supplies. However, the extent to which each doctor desires to carry on his own procedures determines the extent to which this ideal is approached.

In planning laboratory space, it is best to keep two factors in mind. A common mistake is to provide too little counter space, so be generous with it. Secondly, regardless of size, laboratory space should be contiguous with toilet facilities and a pass-through should be provided between the two areas (Fig. 6).

6. X-RAY

If the doctor is planning to use an x-ray machine, provisions for housing it must be made in the planning stage. It is best to decide early exactly what kind of x-ray, darkroom, and

developing equipment the doctor will buy. The planning representatives of the manufacturers can be a part of the planning team then, working closely with the architect or consultant in the preliminary stages of planning.

Nearly all state and city codes now require lead or concrete protection in all interior walls and doors of rooms housing x-ray equipment. If spaces above or below are inhabited, protection is also required in floors and ceilings. Exterior walls need not be protected.

Likewise, there are rather stringent code requirements for the wiring of x-ray rooms and equipment—including separate entrance service in many cases. This should be checked carefully. In most cases, the manufacturer's representative will be familiar with wiring requirements, but if he is not a local resident, he may not be familiar with all the local rules. For this reason, it is best to have this reviewed independently. If a pass-through system is to

Fig. 4 Consultation room.

Commercial

MEDICAL OFFICES

Fig. 5 Examining and treatment room.

be installed, or the through-wall immediate developing system used, the viewing room must be located adjacent to that wall of the darkroom (Fig. 7).

7. UTILITY AND SERVICE AREAS

The location of utility and service areas should be planned carefully in every medical building. These areas include:

Utility Room In a one-story building this room should contain heating and air-conditioning equipment, hot water heater, janitor's sink and space for janitor's supplies. Some states will require separation of the janitor's space from the heating space. This room should not be more than 15 to 20 ft from an outside wall unless the compressor is to be on the roof. Size of the room will depend on the equipment size, and this should be carefully checked in prelimi-

nary planning. A pegboard wall will be handy in the janitor's area. Some states will require one or two fire wall partitions and a fire door in this room.

Storage Spaces Storage and utility space must be provided for patient wraps, staff wraps, utility paper goods and towels, office supplies, old files, and treatment and medicinal needs for at least one full day in each workroom. Casework walls in treatment rooms, laboratory, EKG and BMR room, cast room, and other workrooms, with self-contained sink and counter top, will largely solve the latter problem. The other closets and storage spaces will have to be located convenient to the place of principal use.

Lavatory Rooms The number is dependent upon convenience desired and the expense the doctor wishes to undertake. Facilities adjacent to the waiting room for patients, in the work

area for staff, and at least one adjoining the laboratory are all desirable. The doctor must decide how many he wants in relation to the cost. Wall hung stools and lavatories are recommended.

EQUIPMENT LIST

The numbers appearing in the drawings refer to the equipment list below. This list should be used in conjunction with the diagrams.

1. Lavatory with mirror and towel bar
2. Sink with gooseneck spout
3. Water closet
4. Shower stall
5. Gas line
6. Air line
7. Vacuum line

ELEMENTS OF A DENTAL OFFICE

- Reception (waiting area)
- Business office
- Auxiliary business area
- Consultation or study areas
- Audiovisual, patient education
- Hygienist (variable)
- Treatment rooms (variable)
- Laboratory (variable)
- Darkroom
- X-ray (variable)
- Sterilizing area (variable)
- Staff lounge
- Preventive area (patient education)

Environment and the Professional Image

The dentist, as opposed to a physician (unless a specialist), is *locked* into his environment. In order for a dentist to treat his patient, he must use extensive tools and dental equipment which require fixed or semifixed plumbing and other built-in operating instruments and services. The plumbing services that are necessary to facilitate the operation are water (filtered), air (dry, filtered), suction (wet or dry), waste (vented), and electricity. These are basic and essential input and output elements.

The proper location of services to be performed is essential. The relationship, volume, and use of each area will vary according to individual concepts and needs. Whether the dentist is a general practitioner or a specialist, training and developed concepts or working habits vary, often greatly (Fig. 1).

With the advent of semifixed or flexible equipment, the dentist can change or modify his operative procedures. Recent years have seen radical changes in dental concepts. Government participation through health, educa-

tion, and welfare programs has made dental services readily available to large numbers of the population. This has caused the dentist to expand his facilities and increase the number of auxiliary and parodontal personnel. As a result of both the increase in patients and the constantly changing dental concepts, the need for flexibility in the office is essential.

Reception

The ideal area for a single practitioner should be approximately 150 sq ft minimum, with three walls unbroken by doorways. This allows perimeter of space for maximum seating of five

to seven people. Lighting should be incandescent and diffuse. Both recessed and below-ceiling light sources should be used.

Business Office or Secretarial Area

This is the key or control point in the management of the office. The drawing (Fig. 2) reflects the position the receptionist assumes in relation to waiting area. Full visual control is maintained through closed sliding glass window. Appointment and financial arrangements are consummated at this point. All traffic and flow control is regulated by the nurse/secretary.

Fig. 2 Business office and reception room.

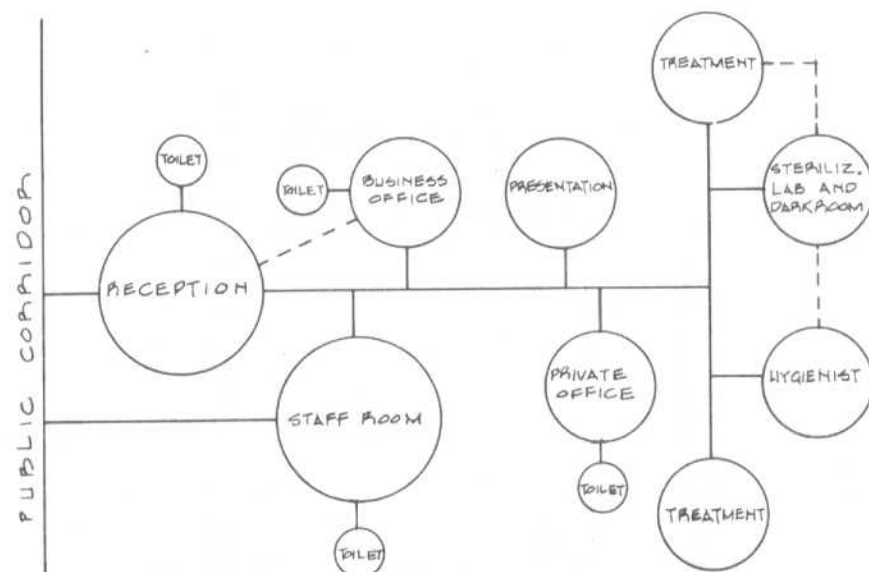

Fig. 1 Dental office flow diagram.

Fig. 3 Private office.

Commercial
DENTAL OFFICES

Private Office

In many offices the private consultation room serves multiple functions, particularly in the last few years, when the cost of space has become so prohibitive and the doctor is interested in increasing the number of treatment rooms within a small overall space. Consultation room desks may take on several shapes, depending on the practice concept of the doctor. He may wish to maintain a formal relationship whereby he faces the patient, who sits opposite the desk. He may prefer an informal arrangement where he and the patient sit around a "table" rather than a formal desk. Active study models and diagnostic models should be located in shallow desk drawers in the desk or in the nearby storage system (Fig. 3).

Treatment Room

The heart of any dental practice is the treatment room. Storage, instrumentation, and comfortable arrangement of equipment and instru-

Fig. 4 Treatment room.

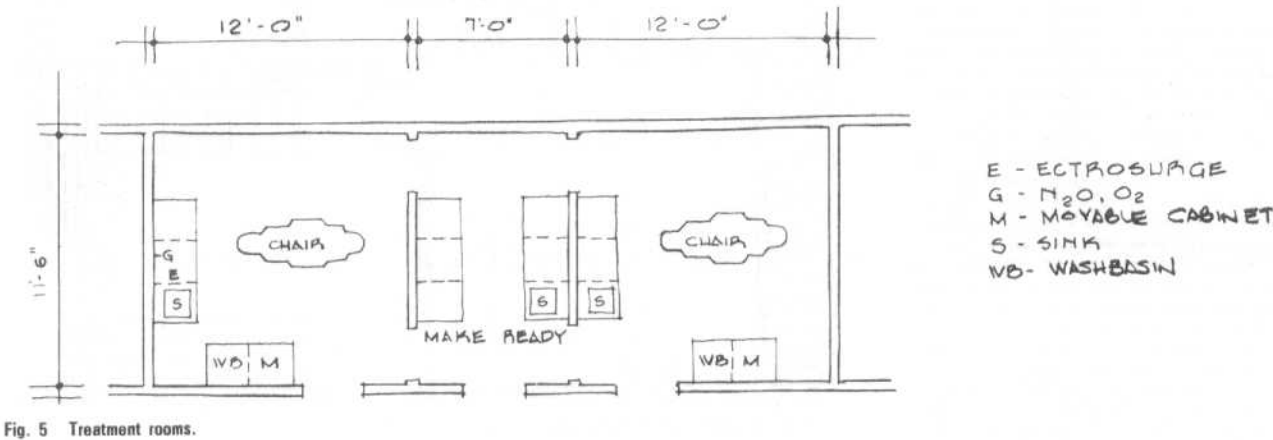

Fig. 5 Treatment rooms.

ments vary with each doctor and doctor's concept as well as with field conditions. The main consideration is to permit the doctor to work in a stressless or comfortable working position and environment. The use and placement of one or two sinks depend upon doctor's concept. Figures 4 and 5 show us a fair amount of storage for supplies and instruments. Adequate work space and counter permits doctor to do bench work without interfering with his chair-side assistant. During the past few years, doctors have experienced a constant change in concepts. Therefore, a degree of flexibility must be reflected in the planning. A mobile instrument cabinet can be tucked under the counter. This is necessary to allow doctor a greater degree of change in his position while treating his patient. The emphasis in the treatment room should be on efficiency, ease of maintenance, and a pleasant atmosphere for the patient, doctor, and staff.

Hygienist's Room

Although the size and function of the hygienist's room may differ from those of the regular treatment room, it is not uncommon to equip this room in the same way as the regular treat-

Fig. 6 Hygienist's room.

Fig. 7 Dental clinic plan.

ment rooms. This will allow the dentist to use this room, when needed, as an additional treatment room (Fig. 6).

Sterilizing Area

The location of the sterilizing area is determined by various factors: dental procedural concepts, the available space in the office, and the psychological image the doctor wishes to obtain. The materials used here should be about the same as those in the laboratory. There should be adequate storage space for

trays and supplies, including the pre-prepared trays as well as those which will be cleaned up at various intervals during the normal working day. The autoclave should be placed out of the reach of children, and the ultrasonic cleaners can be used more efficiently if recessed into the work-counter tops.

The size and location of support areas such as sterilizing, laboratory, dark room, x-ray area, etc., will depend in part on doctor's concept as well as the logistics of the space. A small laboratory unit is merely used for model pouring, trimming, and storage. The size of many

labs is often larger to accommodate expanded technical skills and services. Some doctors split lab duties into two areas.

In conclusion, the dental office is a professional home. Like it or not, the dentist spends the most productive years of his life in it—more than half his waking moments. The office does, therefore, reflect his personality as well as his professional image. It can either assist the doctor to aspire to greater success and satisfaction, or it can sentence him to a professional life of mediocrity and apathy.

Figure 7 shows a plan for a dental clinic.

The rental area per lawyer varies from 230 to 1,212 sq ft. The median is 455 sq ft, and the average is 484 sq ft.

A minimum-size office is illustrated by Fig. 1, which is two modules wide by three modules deep. If a 48-in. module is adopted, the clear dimensions without allowance for partitions will be 8 by 12 ft. The clear dimensions (with partitions 4 in. thick) are given in feet and inches, the maximum desk size is given in inches, and the net area is given in square feet. Larger offices are illustrated by Figs. 2 to 8, and suites are illustrated by Figs. 9 to 19. With each illustration of a suite of rooms comprising a law office, the dimensions and the following square-foot areas (using a 48-in. module) are given:

- * Rental area as customarily measured
 - * Architectural area as measured for preliminary cost estimates
 - * Area (rental) per lawyer
- The following abbreviations and symbols are used with these diagrams:

P—private office
R—reception room or area
S—secretary or stenographers
F—file room or space
L—library or library and conference room
C—conference room
V—vault
U—utility, storage, or work room
T—toilet room
N—north exposure
➤—north exposure
←—exit

THE SMALL OFFICE

Figure 9 shows possible arrangements for a firm composed of only one lawyer. If a single lawyer's office must serve as a library and conference room, and perhaps also accommodate the files, it should be large enough for a conference-type desk and four or five chairs. It is almost essential to have a second room for use as a reception room and secretary's office. It is better to have a separation between the secretary's space and the reception space. The files may be of sufficient volume to require a separate file room.

Figure 10 illustrates arrangements for two lawyers (either partners or cooperators). In Fig. 10c, with a combination library and conference room, the private offices could be somewhat smaller. Figure 11 shows offices for three lawyers. Files should be separated from the reception room and convenient to the clerical employees as in Fig. 11a, or in a separate room as in Fig. 11b. If one office is large enough for conferences and the book collection not too large, the library and conference room may be eliminated. On the other hand, some firms with only two principals have a large enough collection of books to warrant inclu-

LAW OFFICES

sion of a sizable room for use solely as a library as in Fig. 10c. Figure 10a is suitable for a separate building and Figs. 10b and c are for rental space in an office building.

THE MEDIUM-SIZE OFFICE

While firms composed of more than ten lawyers generally carry on a diversified practice and hence choose central locations, some firms of five to ten lawyers may locate near their principal clients. The selection of space in the first story of a commercial building or the erection of a building may be considered. If the clientele is concentrated in a suburban center or small satellite city, or a city of 50,000 or smaller, the scale of land values may be such that first-story space near the commercial center could be considered. Because of the high cost of land in the center of large cities, buildings, to be feasible, must be larger than needed by a single law office; hence selection of space in an elevated office building is often the only answer.

The same area which is planned for three lawyers, as is indicated in Fig. 11a, may be rearranged to accommodate five lawyers, as indicated by Fig. 12a. As rearranged, the area of most of the private offices is too small for conferences with more than one or two visitors, and secretarial space may be insufficient; but where rental rates are high this degree of crowding may be justified. Offices for firms with from five to twelve lawyers are indicated by Figs. 13 to 17. The arrangement shown in Fig. 17 may be expanded or contracted to provide for as few as four lawyers or as many as twenty.

Secretaries' desks should be close to the lawyers' offices. Some firms prefer each lawyer's secretary to be just outside his office door or in an adjacent private office, as in Fig. 17. In general, however, more use can be made of secretarial, stenographic, and clerical employees if some are in a pool to be drawn upon as needs arise.

THE LARGE OFFICE

The planning of space for a large law office may be influenced by the size and shape of the space available. The possibility of securing adequate, well-planned space is enhanced when the firm actively participates in the promotion of an office building.

Figure 18 indicates possibilities of planning large spaces. The same scheme with larger offices could provide for 11 to 18 lawyers, or could be enlarged to accommodate up to 40 or more lawyers. The plan should be based upon a study of the special needs of each lawyer and the relations between members of the firm.

SPACE FOR A COOPERATIVE GROUP

In buildings planned for occupancy by a number of law firms, facilities may be pooled, such as library, vault, utility space, and reception room. Files should be kept in the separate offices and secretaries' spaces. (Fig. 19.)

PLAN ELEMENTS

The most desirable orientation for offices and workrooms varies in different locations, but north is generally preferred. In Figs. 9 to 17, the most desirable orientation is indicated by the location of the letter N. Outside exposure

is desirable for offices and advantageous for large work areas, conference rooms, library, and rest rooms. Central locations are preferred for library, file room, and conference rooms.

The size of rooms is determined in part by the purpose and effect desired, and the furniture chosen. The desirability of commodiousness may be weighed against the rent or its equivalent. If space is air conditioned, smaller spaces may be tolerated. Lack of commodiousness may be offset by the use of rich materials and effective decoration.

FURNITURE

The reception room should have adequate seating in addition to the receptionist's desk, and perhaps side tables for ash trays and magazines. The minimum equipment for a private office is an executive's desk and chair, one or two chairs for visitors, and desk-height bookcases. If desk drawers are not adequate, one or more letter files may be required. For large offices, a sofa, side tables, coffee table, and even a conference table may be included. The furniture of conference rooms may be limited to a table and chairs, but some ornamental furniture may be included. If the room may be divided by a folding partition, two tables may be needed. Lawyers' libraries are for reference, and unless they are to be used also as conference rooms, only one or two small tables are needed. Each secretary's space must have its desk and chair, and files should be placed nearby. For security, file rooms may be included in the plan, and a vault may be needed for valuable papers. Storage spaces may be equipped with shelves, coat hooks, etc., combined with work space for duplicating equipment. Utility rooms are usually required only in separate buildings (rather than rental space) for heating and air conditioning equipment, transformer vault, main switch and meters, etc. A small kitchen or coffee bar may have a hot plate and sink, or more complete conventional kitchen equipment. Toilet facilities are usually required only for large law offices or when the offices occupy complete separate buildings. A couch should be provided in the women's toilet room or in a separate rest room.

INTERIOR DESIGN

Lawyers' offices require little interior decoration, but there is a discernible tendency to make offices homelike. Accessories used should be carefully selected. The most common wall decorations found in lawyers' offices are the certificates of admission to the bar and diplomas. These serve the purpose of assuring clients of the lawyer's qualifications.

By BERNARD SPERO and ERNEST J. HASCH

Efficient office layout calls for the use of certain basic principles which must be modified to meet the requirements of available space, personal habits, and individual preferences. What might be considered efficient by one practitioner is not necessarily so deemed by the next. It is axiomatic that the ones who seem most pleased with their office layouts are the ones who have worked in one or more offices before designing their final suites. Their layout better serves their own habit patterns. Therefore, it is wise to consider each factor as an individual problem and solve it according to the individual requirements as well as to limitations of space.

Waiting Room

The size of the waiting room depends on the practitioner's style of operation. Some adhere closely to their appointment schedule; others do not. Some must accommodate a great many children or expect a family group with many patients. Some use a production-line modus operandi in which assistants process the patients through drop areas or other checkup stations; others prefer to do all patient work-up themselves. So perhaps a "kiddie area" or a "drop area" or both are required. In general, the busy practitioner should be able to accommodate from 10 to 12 people and provide emergency space for 3 or 4 more. About 2 ft of wall space is needed for each person. The idea that waiting room space is nonproductive and therefore wasteful is a fallacy. Few practitioners decrease their waiting room space in subsequent offices; most of them increase it.

If the waiting room is inadequate to contain the patient load, it is helpful to use a system of traffic control in which patients are transferred from the waiting room, in proper order, to operational rooms to await the doctor. This means that extra refraction rooms or combination refraction-treatment rooms are required—or even a field room, a muscle room, or a photography room, if these functions are to be performed independently.

Closets

Space must be provided for patients' wraps. If the space available does not lend itself to installation of a clothes closet, then racks or decorative wall-mounted clothes hangers can be used. Although less efficient, cloakroom facilities can be placed in the receptionist's quarters or in the passageways into the doctor's working areas.

Storage

Storage is an important, and often forgotten, item in office planning. A multitude of supplies are essential to sustain a busy practice, and they should be readily available when needed. Professional accessories and adjuncts are usu-

ally kept in small cabinets in the examination rooms, but general office supplies should be under the commission of the nurse or secretary. Storage cabinets can be built along corridors or above files. Advantage should be taken of any natural structural indentations due to columns or other structural irregularities; these are most useful for construction of cabinets, as they are normally waste space otherwise.

Files

The type of record charts to be used must first be determined and then the appropriate files selected. Room for future files should be apportioned, especially if the office is to be occupied for several years. Files should be accessible to the receptionist and the nurse, and are generally located in the receptionist's office. At times it is advantageous to recess file cabinets into a partition so that only the fronts show, while their bodies jut into a less-needed area of a contiguous room. This can have both aesthetic and functional value. If other space is not available, the file-cabinet area is also a good place for a small refrigerator.

Receptionist

The receptionist should be able to observe the entire waiting room and also control the flow of traffic of patients. After registering the patient, the receptionist usually pulls the record chart or starts a new one if necessary. The chart is placed at the doctor's disposal by means of the particular system used. Different systems are used. The chart can be placed in a rack outside the examination room to be used next, or on a desk in the examination room; some prefer just to select the chart from a rack or a counter top in the reception area or passageway.

Depending on the locality of the practice, the habits of the community, and the duties given the receptionist, one of several reception arrangements can be used. If the practice is located in a community where an informal relationship between public and profession is the rule, the receptionist can be placed behind a desk right out in the waiting room or behind a counter top. Office fees, if uniform, can be quoted and collected over a desk or a counter top. But if histories are to be taken, it is normally advisable to install the receptionist at a desk behind a partition, or to compromise with a half partition.

If the practice is large, or expected to be, it is advisable to provide space for two girls in the receptionist area. This is particularly true if the location is considered a permanent one. If not, a small business office should be planned for any future exigency.

Consultation Room

This is an arbitrary thing dependent on availability of space and on personal preferences. Many physicians prefer to interview patients initially in a private office. Others do so in the examination rooms, thus saving the time involved in transferring the patient from con-

sultation room to examination room. Those who work straight through and then must dash off to other commitments have little need of a private office, per se; but those who wish to stop and rest during the day need the privacy of some office to which they can retire. If excessive space must be taken in order to acquire a particular suite, one room can be adapted for use as a relaxation room, with a cot and beverages and other comforts; or it can be used as a dressing room for the assistants. A room of this type can always be converted to an examination room later, if the need should arise.

Examination Rooms

Examination rooms can be refraction rooms, treatment rooms, minor-surgery rooms, field rooms, photography rooms, muscle and orthoptic rooms, or any combination thereof. There was a time when refractions were done in one room, treatment in another, fields in another, and perhaps slit-lamp microscopy in yet another. Now, there is a trend toward more consolidation, so that practically all phases of a complete eye examination can be done in a single room, thus obviating the transfer of patient from room to room. This arrangement is a time-saver, especially if all parts of the examination are done by the eye doctor; but if assistants do part of the work-up, such as fields or muscle testing or even preliminary visions, there must be separate rooms for the different functions.

Refraction Room

Although only one refracting lane can be used at a time, it is generally conceded that more than one is needed by the busy ophthalmologist. Much time can be lost each day waiting for hats to be donned or doffed, waiting for makeup to be applied, listening to well-meant but time-consuming farewells, and finally waiting for another patient to be brought in and properly settled into position. With a second room available, it is a simple matter to give final instructions, bid a courteous farewell and step into the next room, where a patient has already been seated, with records laid out in a convenient place and instruments properly positioned for immediate use. Someone else can assist the departure of the patient just finished. This is not a very important item when the practice has just started, but as it flourishes, time becomes extremely important.

If it is not possible to have two identical refraction lanes, it is helpful to set up a second lane in a smaller room, perhaps a treatment room, which can be used when the patient load gets unduly heavy. Mirrors or special visual charts can be used, and still the room can be devoted primarily to some other function.

The size of a refraction room depends not only on the space available, but also on the predilections of the practitioner. Some insist on at least a 20-ft lane; others feel that this is relatively unimportant. Most feel that a visual lane of from 15 to 20 ft is satisfactory. Disregarding other factors, the characters on vision charts can be sized appropriately for any dis-

"International Ophthalmology Clinics" Uveitis, *Efficient Office Management*, vol. 3, no. 2, June 1963, Little, Brown and Company, Boston, Mass.

OPHTHALMOLOGICAL OFFICES

tance used. The size of projected characters can be altered by optical means; charts with reverse characters can be used in conjunction with a mirror; charts with direct characters for a 10-ft distance are available; and sometimes it is feasible to use a two-mirror setup, in which one of the mirrors becomes a secondary projector to gain length of projection.

If the longer visual lane is considered necessary, and space is limited, it is sometimes feasible to use tunnels to attain the desired distance and yet conserve space. Tunnels can extend from floor to ceiling, or can even be constructed above files which open out into a different room. In any case, if there is no objection to the so-called "tunnel effect" in the mind of the eye doctor, many space-saving arrangements are possible with this method.

As mentioned before, many doctors now prefer to do a complete eye examination, including treatment, in a single room. Then there must be room for the visual lane with the routine examining equipment (chair, stools, trial lenses, refracting accessories, slit lamp) as well as some field equipment (perimeter, tangent screen) and, no doubt, a consultation desk. There should also be room for medicines, treatment cabinet, and perhaps a treatment table. This would require a minimum of 150 sq ft.

The type of equipment selected will determine, to some extent, the size of the space needed or, conversely, the space available determines, to some extent, the type of equipment which should be used. If the larger "deluxe-type" patients' chair is used, it should be positioned about 4 ft from a wall in order to utilize its adjustable and reclining features; and then a treatment table might not be considered necessary. On the other hand, the smaller, less adjustable chair can be placed close to the wall; but a treatment table is needed for tonometry, treatment, and minor surgery unless these functions are to be done in another room.

Sometimes the positioning of the projector (for vision lanes) presents a problem, perhaps because of corners or extraneous paraphernalia around the patients' chair. A recent innovation is the use of remote-control projectors. These projectors, now available, can be mounted in an out-of-the-way position and be completely controlled by fingertip switches on or around the lens cabinet. With this arrangement, there is no need to reach in front of a patient, or turn awkwardly, to change the characters projected.

Furnishings

OPHTHALMOLOGICAL OFFICES

If two refraction rooms are to be used, it is better to have them adjacent or adjoining, or separated by no more than a smaller treatment or minor-surgery room.

Miscellaneous Rooms

Since the various services required of the ophthalmologist are so interrelated, refraction rooms now usually contain some treatment facilities. But it is still helpful to have a room available, possibly smaller, which can be used for treatment, minor surgery, and fields. One such room for every two refraction rooms should be adequate, even in the larger multi-manned practices. It is advisable to have a vision lane in the miscellaneous rooms whenever possible. Almost any distance can be used to create a satisfactory vision lane.

Minor surgery can be done in any chair with a headrest and a reclining back, but a chair-table or a stationary treatment table is considerably more comfortable to the patient. The examining chair which can be converted into a

flat treatment table can serve several purposes. It can serve as a general treatment chair for tonometry or minor surgery; it can be a refraction chair; and it can be positioned at the prescribed distance from a tangent screen so that central fields can be taken from the same chair, thus making efficient use of a smaller room.

Orthoptic rooms, as such, are seldom used unless the volume of the practice affords the use of an orthoptist. The diagnostic work performed by most eye doctors is done in one of the other operational rooms; but if orthoptic treatments are to be given, a separate orthoptic room is indicated.

Treatment, minor surgery, and fields can usually be done in a room of about 100 to 130 sq ft, with smaller rooms serving well for any single one of the functions.

Figure 1 is a plan designed to give the nurse and the receptionist complete control of the traffic flow. The receptionist controls the patients in the drop area and refers them to the nurse, who does primary work-ups. Then the patients are directed to one of the doctor's

refraction rooms. The refraction rooms are identical, and should be equipped identically. There is a room for treatment and minor surgery, and the nurse could also use it in addition to her field room. Storage is centrally located in the corridor.

Figure 2 shows three refraction rooms, one nurse's office, and three miscellaneous rooms to facilitate processing a large practice through this suite. The nurse and any other assistants have access to all parts of the suite, and the nurse has a 13-ft vision lane over the files. All assistants to the doctors can cooperate efficiently to route patients properly according to the system used, and still oversee the overall operation from various vantage points. The doctors, under a proper system, will have several rooms in which they can perform the various functions required. For instance, the photography room, which is seldom used as such, can be used for tonography, gonioscopy, and orthoptics, or even as a personnel lounge. The children's waiting room can be kept under constant surveillance.

Car Classification

By CHARLES M. BOLDON and RICHARD F. ROTI

1971 DOMESTIC AND IMPORTED PASSENGER CARS—BY CLASSES

The popular domestic and imported passenger cars are listed below in seven classes. The rating categories are established on the basis of square feet of floor area covered by a vehicle. Class 60, for example, contains vehicles where the resultant of length \times width dimensions fall into the 60.0 to 69.9 sq ft area range. Class 70 covers the 70.0 to 79.9 sq ft area range.

It can be noted that the new domestic subcompacts, Pinto, Vega, and Gremlin, fall into the upper areas of Class 70, differing considerably from Colt in the middle of Class 60.

Apart from Volvo and Mercedes 280 SL—representing approximately 1.2 percent of the industry and 4.70 percent of all foreign makes—imports are not considered a substantial factor in Class 80.

Listings in Class 110 for Ford Custom/Galaxie/LTD, Plymouth Fury/GT and Chevrolet Biscayne/Impala are based on standard sedan dimensions. The high proportion of station wagons sold of these models has raised these vehicles into Class 120.

Vehicle Width

The trend of overall width from 1927 to date has been about 10 or 12 in. The increase was to provide for generous three-passenger room in the front seat of the wider cars and to approach comfortable three-passenger capacity in the smaller. Any increase in the width of larger cars would be to provide for four people. This would amount to another 18–20 in. Manufacturers do not anticipate a one unit increase to a four-passenger front seat. The current growing demand in passenger cars is for two-passenger unit seats, a feature previously confined to vehicles of special interest. Width of motor vehicles using federal highways is limited to 96 in. maximum in most states. The exceptions, Connecticut, Maine and Rhode Island, allow 102 in. maximum dimensions.

Most of the width gains took place in the 1930–1942 period. The smallest cars widened out 4.4 in. (from 65.8 to 70.2 in.). The big three-passenger cars increased 6.4 in. (from 65.5 to 71.9 in.). The overall average of all makes increased 6.5 in. (from 68.5 to 75.0 in.). The greatest gain was an increase of 8.8 in. by the largest luxury cars.

A concealed fact in the figures is that running boards disappeared during this period. In 1930 running boards 6 to 8 in. wide on each side were eliminated in the bellying out process to obtain three-passenger units.

The gap between today's widest car and narrowest car is once again increasing. The domestic "mini-compacts" led by the Colt at 61.4 in., Vega at 65.4 in., Pinto at 69.4 in., and Gremlin at 70.6 in. contrasts sharply with the 79–80 in. traditional "big three" and luxury cars.

TABLE 3 Classification System

Class 60—Subcompacts:

1. Toyota Corolla/Sprinter
2. Datsun B110 Sedan
3. Toyota Corolla Wagon
4. Datsun SPL311 Roadster
5. Volkswagen Beetle
6. Dodge Colt
7. Toyota Corona
8. Toyota Landcruiser
9. Datsun PL510 Sedan
10. Peugeot 304

Class 70—Subcompacts:

11. Datsun WPL510 Sedan
12. Volkswagen Super Beetle
13. Porsche—all models
14. Datsun 240Z
15. Volkswagen—Karmann Ghia
16. Volkswagen Type 3/Square back
17. Toyota Corona Mark II
18. Mercury Capri
19. Chevrolet Vega
20. Audi Super 90/Sta. Wgn.
21. Ford Pinto
22. American Gremlin

Class 80—Compact:

23. Volvo 1800 E
24. Volkswagen 411 Sedan
25. Peugeot 504
26. Mercedes 280SL
27. Volkswagen Sta. Wagon
28. Toyota Crown
29. Toyota Crown Wagon
30. Audi 100LS
31. Volvo 142/144/145 Wgn.
32. Toyota Landcruiser Wgn.
33. Chevrolet Corvette
34. American Hornet
35. Ford Maverick
36. Volvo 164
37. Mercury Comet GT
38. Mercedes 220/250

Class 90—Compact:

39. Mercury Comet Sedan
40. Plymouth Valiant/Duster
41. Dodge Dart/Custom/Swinger
42. Chevrolet Nova
43. Mercedes 280S/280SE
44. Dodge Demon
45. Mercedes, 280SE, Coupe 3.5
46. Plymouth Barracuda
47. Chevrolet Camaro
48. Mercedes 280SEL
49. Ford Mustang

50. Pontiac Firebird

Class 100—Intermediate:

51. American Javelin
52. Rolls Royce—Silver Shadow
53. Dodge Challenger
54. Rolls Royce—Formal Sedan
55. Mercury Cougar
56. Chevrolet Chevelle/Malibu
57. Pontiac LeMans
58. Dodge Charger RT
59. Pontiac GT
60. Chevrolet Monte Carlo
61. Oldsmobile Cutlass "S"
62. Buick G.S.
63. Ford Torino
64. Oldsmobile F-85

Class 110—Standard

65. American Matador
66. Oldsmobile Cutlass Sedan/Coupe
67. Oldsmobile Cutlass Supreme
68. Buick Skylark
69. Plymouth Satellite/Road Runner
70. Mercury Montego
71. Dodge Coronet/Custom/Brougham
72. Dodge Charger 500/Coupe/SE
73. American Ambassador
74. Ford Thunderbird
75. Pontiac Grand Prix
76. Chevrolet Chevelle Wgn.
77. Plymouth Fury/GT
78. Ford Custom/Galaxie/LTD
79. Lincoln Mark III
80. Chevrolet Biscayne/Impala

Class 120—Luxury:

81. Buick Riviera
82. Dodge Polara
83. Pontiac Catalina
84. Oldsmobile Delta 88
85. Buick LeSabre
86. Oldsmobile Toronado
87. Cadillac El Dorado
88. Chrysler Newport/New Yorker
89. Chevrolet Impala Sta. Wgn.
90. Mercury Monterey/Custom
91. Mercury Marquis/Brougham
92. Pontiac Bonneville
93. Oldsmobile Ninety-Eight
94. Lincoln Continental
95. Cadillac Coupe De Ville
96. Cadillac Sedan De Ville
97. Buick Electra
98. Chrysler Imperial
99. Cadillac Fleetwood 60

From *A Parking Standards Report Vol. I*, by Parking Standards Design Associates, a joint venture of Conrad Associates & Richard F. Roti & Associates, 1971.

Fig. 2 Ramp breakover angle.

Fig. 3 (a) Angle of approach. (b) Angle of departure.

Overall Length During the period of 1930-1942 major changes were made in car length which had a severe effect on garage design and investment cost per car space. The smallest cars increased over four feet in length (from 140.1 in. to 193.5 in.). The family sedan, Ford, Chevrolet and Plymouth "Big Three" increased 3½ ft (from 152.9 in. to 196.1 in.). The average of all makes showed an overall increase of 37½ in. (from 169.3 in. to 206.8 in.). The luxury cars registered a 21 in. gain (from 204.9 in. to 225.9 in.).

The 12-year period from 1946 to 1958 brought out two trends. Rambler as the smallest car pioneered the reversal toward smaller cars in 1952. In 1954 the low-price family sedan (Ford, Chevrolet and Plymouth) began a 7-year increase in car size from 99 to 118 sq ft.

From 1957 to 1960 the "tail-fin" explosion

occurred leading to a buyers' revolt against stretched-out sheet metal, followed by an increase in imports and introduction of domestic compacts. Immediately following introduction of United States compacts the car manufacturers began an inching up process until the 85 sq ft compact was 90 sq ft as evidenced in the 1963-1970 "shortest car" indication.

During the same period the "low-price three" began an active 7-year growth period projecting all three into the larger size category Class 120.

Ramp Breakover Angle

The ramp breakover angle is the measure of ability of the car to break over a steep ramp, either climbing or descending, without scraping (see Fig. 2). The Society of Automotive Engineers calls for a minimum of 10 degrees as a design standard. A number of models have not met this standard in recent years. The average for all groups has remained relatively constant during the period 1958-1971 despite appreciable vehicle height reductions.

The ramp breakover angle influence can be altered thru use of design techniques. Transitional blends top and bottom of ramps composed of two or more break points can multiply the ramp steepness, with workable break angles, beyond the normal capacities of car or driver. In existing structures these problems are overcome by building a pad of asphalt or concrete each side of the break point. In this manner cars having a low breakover angle can negotiate potential critical points without scraping.

Long wheelbase cars combined with low center clearance are most susceptible to inadequate breakover angles. Buick Riviera, Pontiac Tempest, Oldsmobile Toronado, and Lincoln had lower ramp breakover angles in 1970 than Society of Automotive Engineers design standards recommendation.

Fig. 4 Ramp slopes. (Transitions are required only if ramp slope exceeds 10 percent.)

(a)

(b)

Fig. 5 Driveway exits.

Angle of Departure

A reasonable minimum value is necessary to reduce the incidence of tailpipe and rear bumper dragging. The standard calls for a minimum of 10 degrees, violated only in the 1957-1959 period. Only one 1970 car, Mercury, met the minimum standard. Most cars are substantially above 10 degrees. The most critical condition is at driveways where the apron is steep, or a combination of excessive crown to gutter and apron slope.

Angle of Approach

The trend of approach angle of domestic cars from 1948 to 1962 indicates a drop in the 1957-1959 period below 15 degrees. The standard developed in 1960 by the Society of Automotive Engineers calls for a minimum value of 15 degrees. The standard has been maintained up to 1970 when reduced by Chrysler and Dodge to 14.0 and 14.6 degrees respectively. (See Fig. 3.)

Ramp Slopes

The maximum ramp slope should be 20 percent. For slopes over 10 percent, a transition at least 8 ft long should be provided at each end of the ramp at one half the slope of the ramp itself. (See Fig. 4.)

Driveway Exits

A ramped driveway exit rising up to a public sidewalk must have a transition section that is

PARKING GARAGES

almost level (maximum slope: 5 percent) before intersecting the sidewalk to prevent the hood of the car from obscuring the driver's view of pedestrians on the walk. This transition should be 16 ft long. (See Fig. 5a.)

Property line walls should also be regulated so as not to interfere with the driver's view of pedestrians on a public sidewalk. Wherever an exit driveway is parallel and adjacent to a property line wall which extends all the way to a sidewalk, the edge of the driveway should be physically established, by curb or railing, at least 6 ft from that wall. For each foot that the wall is held back from the sidewalk, the required distance between driveway and wall may be reduced by one foot. (See Fig. 5b.)

RAMP SYSTEMS*

A number of different interfloor ramp systems can be used to enable vehicles to traverse the approximate 10-ft (3-m) elevation between parking levels. Some of these systems provide separate and exclusive ramps, while others make use of continuous sloping floors that accommodate both parked vehicles and interfloor travel.

Ramps may be straight, curved, or a combination. No single ramp system is best for all applications. The choice should be based on site shape and dimensions and parking demand characteristics. Ramps may be designed for one-way or two-way traffic movement. However, one-lane-wide ramps should not be operated on a reversible two-way basis.

In some instances, site topography will allow direct access to several parking levels from the street system. This is a desirable arrangement, since it leaves more space for parking and provides more flexibility for traffic distribution between the street system and parking facility.

Time and convenience are important to ramp travel and should be considered in any comparison of ramp types. Actual travel time on ramps varies little among different ramp system types; however, some ramp systems have more potential for delay caused by conflicting traffic movements that limit ramp capacity. Other factors influencing ramp design include accident hazards, construction cost, and ability to accommodate vehicles and drivers conveniently.

Analysis of Ramp Movements

A ramp system includes any portion of storage floors used by vehicles moving between levels. Nearly every successful ramp system requires vehicles to follow an approximately circular path when traveling between parking levels. The number of 360-degree rotations required to circulate through the garage and parking structure height are major concerns, particularly in self-park designs.

It is generally desirable to limit the maximum number of complete rotations to five or six. Depending on ramp system type, this will control the maximum desirable number of parking levels and limit the number of parking spaces a driver must pass during garage travel.

Drivers are sometimes distracted or disturbed by the awareness of height when traveling on upper parking levels—a condition that can be accentuated if parking levels extend higher than adjacent buildings. To reduce driver distraction,

parapet walls along driving ramps should be designed to limit the driver's view of surroundings outside the parking structure.

Clearway and Adjacent Ramp Types Ramp systems may be divided into two types, based on the amount of interference between ramp traffic and parking-unparking operations. Ramp systems designed on the "clearway" principle provide interfloor travel paths completely separated from potentially conflicting parking-unparking movements. Ramp systems in which part or all of the ramp travel is performed on access aisles may be called the "adjacent parking" type. The number of parking stalls adjacent to the ramp may vary from a small number to the total capacity of the facility. (See Fig. 1.)

Clearway ramp systems provide the safest movement with least delay and, except for sloping floor designs, are preferred for self-park designs. However, the clearway ramp system is seldom feasible for small garage sites.

An adjacent-parking layout requires less area per parking stall because of the twofold use of travel paths, and consequently can be used to advantage on smaller land parcels. However, adjacent-parking ramp designs are more susceptible to traffic movement delays and potential accident-causing situations.

The actual travel speeds for free-moving vehicles on the two types of ramps do not vary greatly. Delays on the adjacent-parking type ramp system caused by parking-unparking maneuvers are difficult to measure but must be recognized as a sizeable quantity. Delays will be greater on parking levels nearest the street level, since these levels always have larger numbers of vehicles in the circulation system.

Concentric Versus Tandem Ramp Design Ramp systems also can be classified as concentric or tandem, depending on whether the travel paths of vehicles moving up and down between parking levels revolve about the same or separate centers. Helically-curved (spiral) ramps are usually built concentrically to save space and to provide flatter grades. Straight ramp systems are designed in either concentric or tandem configurations.

Vehicles traveling on a ramp system may move either clockwise or counterclockwise. Counterclockwise rotation is generally preferred in the United States and other countries where drivers customarily sit on the left side in vehicles since it places drivers on the inside of turns, enabling better vehicle handling.

Parallel Versus Opposed Ramp Design For vehicles to rotate in the same direction on a ramp system, up and down ramps must slope in opposite directions, requiring ramp surfaces to be op-

posed. If up and down ramps slope in the same direction, ramp surfaces are parallel and vehicles must rotate in opposite directions.

While no significant difference has been observed in operational ease, it is obvious that opposed ramp types are safer, since all vehicles must travel in the same direction. Parallel ramp systems are considerably cheaper to construct, however.

Geometric Ramp Types

For safety, convenience, and traffic operating efficiency, the path followed by the ramp through traffic on any floor of a parking garage should be short, with minimum turns and traffic crossings. Ramp arrangements within a garage should be consistent, in order to be as simple and comprehensible as possible.

Ramp design and arrangement are influenced by (1) orientation of ramp traffic flow to main-floor street entrance and exit points and to other ramp systems that might exist in larger garages, (2) conformance of ramps with access aisles throughout each floor area, and (3) site dimensions.

Straight-Ramp Systems Ramps within a straight-ramp system usually should be "stacked" one over another for construction economy and traffic circulation uniformity. The stacking of ramps creates a "ramp-well." From a plan view, the sum of the system's ramp-well areas and the floor area containing aisles used by ramp portal-to-portal traffic is the ramp system's area, or envelope. This extends vertically through the parking structure (with the possible exception of roof and/or basement levels).

For straight-ramp garages, the ramp system is usually rectangularly shaped (ignoring curved ramp ends), with the ramp well(s) along the structure's longer-side dimension. This is because more horizontal distance is required to satisfy ramp grade criteria than to accommodate vehicular movement between ramp ends.

Figure 2 illustrates a basic straight-ramp system having a ramp-well on one side only. In this system, vehicles follow an elliptical path, most of which is on flat surfaces. Figure 3 is a parallel straight-ramp system, with ramp-wells on two sides of the structure. Turning movements for the up and down ramps are performed in different areas, while the floor travel is performed in a two-way movement along the same aisle. Depending on structure width, the floor travel could be directionally separated. The systems represented in Figs. 2 and 3 are both very adaptable to entrance and exit points on the same street.

Figure 4 is an adjacent-parking type opposed straight-ramp system. Travel paths for through up and down movements fall in the same aisle,

Fig. 1 Parking garage examples that incorporate adjacent-parking ramp systems for traffic entering and clearway ramp systems for traffic exiting the facilities.

* *Parking Garage Planning and Operation*, Eno Foundation for Transportation, Inc., Westport, Conn., 1978.

PARKING GARAGES

eliminating traffic crossing points. Figure 5 illustrates a clearway type opposed straight-ramp system. Ends of opposed ramps on the main floor are pointed in opposite directions, making this type suited to structures with entrance and exit points on separate streets. This design can be adapted to entrance and exit points on the same street, but requires a 180-degree turn on the main floor—necessitating additional space.

Straight-ramp systems are advantageous in relatively narrow buildings. They require less floor

area than helically-curved ramps and are simple to construct, particularly in existing structures being converted to parking garages. However, sharp turns, necessary to get on and off straight ramps, are disadvantages.

Split-Level or Staggered-Floor Systems. The staggered-floor parking garage, invented by Fernand E. d'Humy, is now generally referred to as a split-level garage. It is constructed in two sections, with floor levels in one section staggered vertically by one-half story from those in adjacent sections. Short straight ramps, sloped in alternate directions and separated by the distance required to easily make a 180-degree turn between ramps, connect the half-stories.

Any combination of straight ramps can be applied to the split-level floor systems. Traffic rotation direction may be the same, in which case the aisles are one-way, thereby reducing conflicts. Turning paths may overlap, requiring less space for the ramp system. Rotation can be provided also in opposite directions, which simplifies ramp construction by having up and down ramps on the same plane.

The division between split-level structure halves

may be perpendicular to the street or parallel. In the latter case, either the front or back half may be elevated. Split-level floors can overlap as much as 5 to 6 ft (1.5 to 1.8 m) to increase space efficiency and make narrow sites workable.

Figures 6 through 9 illustrate various types of split-level configurations. Figure 8 is the most common type.

Split-level designs are particularly applicable to small, high-cost sites where maximum use of space must be achieved. Construction is relatively simple, and the design fits well on rectangular sites. This system is efficient in terms of floor space per vehicle parking stall but, like all ramp systems employing adjacent parking, frequent conflicts may arise between circulating traffic and parking-unparking vehicles.

One variation in the split-level system uses three separate sections, with the two end sections at equal elevations and staggered one-half story with respect to the center section (see Fig. 9). Fifty percent fewer turns are required, thereby reducing travel time. However, vehicles parked on the end sections must be driven an extra half-floor when entering or leaving. "Wrong way" ramp travel is also a greater possibility with this type of design.

Sloping-Floor Systems The sloping-floor parking garage, in its simplest form, contains two adjacent parking modules tilted in opposite directions, with cross-aisles at each end so that vehicles traveling the length of both aisles make a 360-degree turn to move up or down one complete parking level (Fig. 10). Thus, there is no area set aside for ramps in the ordinary sense. The cross-aisles may be sloped or level.

Parking industry experience indicates that the sloping-floor design is well-suited to self-park operations. The relatively flat floor slope (customarily ranging between 3 and 5 percent) permits comfortable parking and pedestrian walking. Because parking is adjacent to the interfloor circulation system, each entering customer has an oppor-

Fig. 2 Parallel straight-ramp system with ramp-wells on two structure sides.

PARKING GARAGES

tunity to park in the first available space. However, the operational problems in adjacent parking can cause congestion during peak out-bound movements if clearway-type express ramps are not used.

Floor-to-floor travel distance is greater in sloping-floor garages than in other types of ramp garages. However, this is offset somewhat by the opportunity for greater travel speeds due to flat slopes and longer tangents.

For large structures it is desirable to have only part of the floor area sloped, with level floor sections at ends to form cross-aisles. Ramp connections at midpoints of opposite sloping floors permit one-way traffic circulation (Fig. 11). It is possible to achieve one-way traffic circulation in sloping-floor layouts, with parking along aisles on every level, by using two sloping-floor garage units placed end-to-end. In the level center section where the two units meet, traffic flow can change from up to down and vice versa. This permits flexibility for angled parking, limited only by available site width (Fig. 12).

Helically Curved Ramp Systems The helix (spiral) ramp can be a single surface that permits vehicles to travel on a continuous helical path between parking levels. When two-way traffic is handled on a single helix, the outer lane is used for up movements, since it has a larger radius of curvature and lower grade. Up movements are usually counterclockwise and down movements clockwise.

Helical-ramp entrance and exit points can be located on the same side or opposite sides of the ramp coil. In either case, ramp access points are located directly above each other on each succeeding floor. Helically curved ramps should be of the clearway type. Examples are illustrated in Figs. 13 and 14.

The double helix system (Fig. 14) uses two helical-path surfaces that are sloped in opposite directions. One surface can be used for up movements, the other for down movements. The two sloping helical surfaces may be separated or they may be interwoven. Vehicle movements for both up and down travel directions are made in the same direction of rotation. In the United States and other countries using left-side drive vehicles, counterclockwise rotation is preferred.

Fig. 11 Sloping-floor system with crossover ramp of mid-point.

Fig. 12 Double sloping-floor system with midpoint crossover.

Interwoven double helix systems are popular in tall structures (10 to 12 parking levels) because the number of 360-degree turns can be reduced by using two separated helical surfaces to serve alternate parking levels.

Traditionally, curving ramps are said to be continuous where they provide 360 degrees of rotation between two parking levels. The noncontinuous helically curved ramps that provide rotation through 180 degrees are commonly referred to as semicircular—although this definition is not quite correct, since the curved section is helical in shape.

Helically curved ramps are most often located in corners of rectangular structures to minimize floor-space loss, or they are located outside the structure when additional site area is available. Helically curved ramps require more space than straight ramps, but they can offer better traffic operation by providing gradual turning as compared to sharp turning movements usually required at ends of straight ramps. In addition,

Fig. 13 Helical ramps such as this one can be used effectively for express exiting.

Helical ramp systems can often be advantageous for structures situated on odd-shaped sites.

Fig. 15 Examples of straight and helical express exit ramps.

superelevation at ends of straight ramps may require undesirable warping of floor areas.

Express Exit Ramps Large parking structures with frequent high-turnover conditions may be served best with an express ramp for one direction of travel—usually for exiting traffic. Express exits can be curved or straight, and are designed always on the clearway principle, providing one-way traffic movement (Fig. 15). They are generally desirable to serve high-turnover transient patronage. They improve operating efficiency by reducing travel time and conflicts—but may add significantly to structure costs, since they increase the area prorated to each parking space in determinations of space-use efficiency.

Ramp Standards

Ramp design parameters governing the acceptability of such ramp features as maximum gradient and minimum radius of curvature have evolved from garage operating experience. The following discussion presents standards generally used by the parking industry.

Ramp Grades Ramp grade (slope) is computed by multiplying floor-to-floor height by 100 and dividing by the ramp length. The difference between ramp length measured along the slope or horizontally is negligible. Grades on curving ramps are measured along the outer ramp pavement edge.

Maximum practical ramp grades are principally limited by safety considerations and the psychological effect on drivers, with hill-climbing and braking abilities of automobiles being a secondary factor. Steep ramps slow traffic movement and can be particularly hazardous when wet, requiring drivers to be excessively cautious.

PARKING GARAGES

Fig. 16 Relationship between floor-to-floor height, ramp grade, and length. (SOURCE: Edmund R. Ricker, *Traffic Design of Parking Garages*, The Eno Foundation for Highway Traffic Control, 1957, p. 115.)

*Ramp slopes (grades) less than 10 percent can be blended satisfactorily with an 8-foot transition length.

Fig. 17 Method of blending ramp and floor grades. Vertical scale is exaggerated to show detail. (SOURCE: Adapted from Edmund R. Ricker, *Traffic Design of Parking Garages*, The Eno Foundation for Highway Traffic Control, 1957, p. 117.)

Fig. 18 Curved ramp system with tangent sections.

For self-park designs, maximum ramp grades should not exceed 15 percent; however, 20 percent maximum ramp grades for attendant-parking garages are acceptable. In parking structures where pedestrians are expected to walk on vehicle ramps, grades preferably should be no more than 10 percent.

Figure 16 graphically relates ramp grade and length with floor-to-floor heights. For instance, this graph shows that for a slope of 13 percent and a rise of 9 ft or 2.7 m (floor-to-floor height), a ramp length of 70 ft (21.3 m) long is required. Similarly, a floor-to-floor height of 11 ft (3.4 m) and a ramp length of 90 ft (27 m) results in a slope (ramp grade) of 12 percent.

The maximum preferable grade for sloping-floor self-park garages is 4 percent, and in attendant-park garages, 10 percent. Angle parking in sloping-floor garages should be 60 degrees or greater, to minimize gravity roll-back of vehicles.

Ramp Grade Transition Design Critical vehicle clearances, driver comfort, and safety considerations influence the design of ramp ends where they meet flatter floor surfaces. Ramp breakover angle, and the angles of approach (affecting front overhang of vehicles) and departure (affecting rear overhang) are critical vehicle clearance points. These angles are established for stationary vehicles with normal equipment and load, including passengers and fuel.

Minimum radius is 32 feet to outer pavement edge for helical ramp or other turning path. A 35- to 37-foot radius is most desirable.

Fig. 19 Helical ramp dimension standards. (SOURCE: *Parking Principles*, Special Report 125 Highway Research Board, 1971.)

Ramp breakover angle is limited by wheelbase and vehicle ground clearance, and is a measure of an automobile's ability to be driven over the crest formed by two converging surfaces without scraping its underside. Ramp breakover angle varies inversely to wheelbase.

Angles of approach and departure are limited by vehicle front and rear overhang and ground clearance. These vehicle clearance angles determine an automobile's ability to roll over the sag point (lower end of ramp) formed by different grades without scraping or touching the pavement surface. The angle of departure is more critical because the rear overhang of vehicles is generally longer than the front overhang.

Standards established by the Society of Automotive Engineers limit the ramp breakover angle to no less than 10 degrees; angle of departure, no less than 10 degrees; and angle of approach, no less than 15 degrees. Vehicles designed to these minimum standards theoretically are able to traverse sag and crest sections at the bottom and top of a 17.6 percent ramp grade, and to move to flat floor grades without need for a grade transitioning (blending) area.

However, centrifugal force, causing vehicle suspension to compress when crossing a sag point, even at low speed, can result in vehicles scraping pavement surfaces. Without grade transitioning at the ramp crest, driver sight-distance can be limited momentarily, and crossing abrupt grade changes can be uncomfortable for drivers and passengers. Therefore, ramp grades should be blended gradually or transitioned to flatter floor surfaces.

A practical method of blending ramp grades to relatively flat floor levels involves using a minimum 12-ft-long (3.7-m) transition slope equal to one-half of the ramp grade. Figure 17 illustrates this ramp grade transitioning method. Ramp grades of less than 10 percent can be blended satisfactorily with a transitioning slope shorter than 12 ft (3.7 m).

Ramp Width and Radii For one-way straight ramps, minimum acceptable width is 12 ft (3.66 m); and for two-way straight ramps, where opposing traffic flows are not separated, 22 ft (6.71 m) is the recommended minimum width. Where a barrier is used between lanes to separate traffic flows, each lane should be at least 12 ft (3.66 m) wide for tangent lengths. Circular ramp lanes generally should be 14–18 ft (4.3–5.5 m) wide.

The repeated turning movements of vehicles traveling between parking levels is a primary design consideration. The spiraling path radius must be kept minimal to conserve space and reduce travel distance. However, very sharp and unrelieved turning will produce a dizzying effect on drivers. To minimize this effect, ramp systems can be laid out with sharp curves separated by short tangents or less sharply curved sections (Fig. 18).

Lateral clearance for a vehicle traveling a curved path is determined by a vehicle's outermost corner point radius (usually the front bumper) when it is turning on a minimum radius. The inside edge of travel lane radius must be less than the minimum inside rear-wheel radius—but not much smaller, or drivers will attempt to enter the ramp at too sharp an angle. The relationship between these radii depends on relative vehicle position, which is determined by maximum steering angle and driver steering input, extreme corner dimensions, and speed. Clearance is usually provided for the vehicle with the largest outermost corner point radius.

Minimum outside radius for a single-lane helical

PARKING GARAGES

ramp is 32 ft (9.75 m); however, an outer radius of 35–37 ft (10.67–11.28 m) is desirable. With helically curved two-lane ramp surfaces, the outer lane need not be as wide as the lane used on the inside path. The outer lane radius is less restrictive, allowing drivers to turn at a flatter angle that requires less effective width for a travel path (Fig. 19).

Ramp Turn Superelevation Vehicles traveling on curved paths are acted on by centrifugal force proportional to the square of the velocity and inversely proportional to the radius of curvature. This centrifugal force must be balanced by other forces that are developed by side-friction of the tires on pavement, and superelevation (banking) of the ramp surface. Although speeds in parking garages are low, turning radii are much smaller than those required for street or highways, thus resulting in rather large centrifugal forces. Ramp curves should not be superelevated too steeply, because very slow drivers may have difficulty in keeping away from the inside edge of the ramp pavement and fast drivers may be encouraged to drive at speeds greater than conditions of grade and sight-distance safely permit.

Garage ramp superelevation should be approximately $\frac{1}{2}$ -in./ft (approximately 4 cm/m) of ramp width at the point of sharpest turning, with lesser amounts adjacent to straight sections or storage floors.

Ramp Appearance Some motorists are reluctant to use ramp garages because travel paths in parking garages may combine narrow lanes, steep grades, and sharp turns. Even drivers accustomed to garage parking depend on appearance and "feel" in maneuvering their vehicles.

Consequently it is desirable to use architectural and optical effects that will give drivers confidence and reduce possible adverse psychological effects of driving in restricted spaces. An obvious means is to make sight distances as great as possible and to provide abundant illumination.

The optical trick of obscuring horizontal and vertical lines of reference may be used to reduce the apparent steepness of ramp grades. Ramp walls can be painted with stripes contrasting to wall color, parallel to ramp surface or at steeper angles. The normal angles between vertical columns and the travelway can be obscured by paint markings, or adjacent structural features may be built with architectural lines parallel or perpendicular to ramp surfaces.

Ramp structures should be as open as practicable, to provide sight distances and to reduce closed-in impressions. In locations where icing conditions are common, ramp systems should be placed in building interiors or otherwise protected from weather.

Ramp illumination should be given special attention. Wall openings should not be allowed where outside light sources could blind drivers. Artificial lighting should take the form of diffused illumination, and reflectors should be pointed away from the direction of travel.

PARKING GARAGES

Typical Designs

In the following pages the functional plans and design features of five self-parking facilities are presented. They are typical of the modern

garage planning that has evolved during the past several years.

In Fig. 1, the plan for a twin-spiral garage is shown. The ramps, situated in opposite corners, are angled to facilitate the movement from the floors to the ramps. Entrances and exits have been provided on two streets on separate levels to take advantage of the different elevations.

The waiting area—two elevators, rest rooms, cashier's booths, and vending machines—is in the center of the garage. A retail area extends

along the entire frontage of one of the streets and has a depth of about 85 ft. The fourth level of the garage, or roof deck, extends over the retail area. Ninety-degree parking is employed throughout the facility.

A staggered-floor or split-level garage is shown in Fig. 2. The ramp systems feature separated one-way operation, and access is on only one street. The overall dimensions of the 352-space facility are 120 by 240 ft. Ninety-degree parking is utilized throughout the four floors. The cashier's booth is at the entrance,

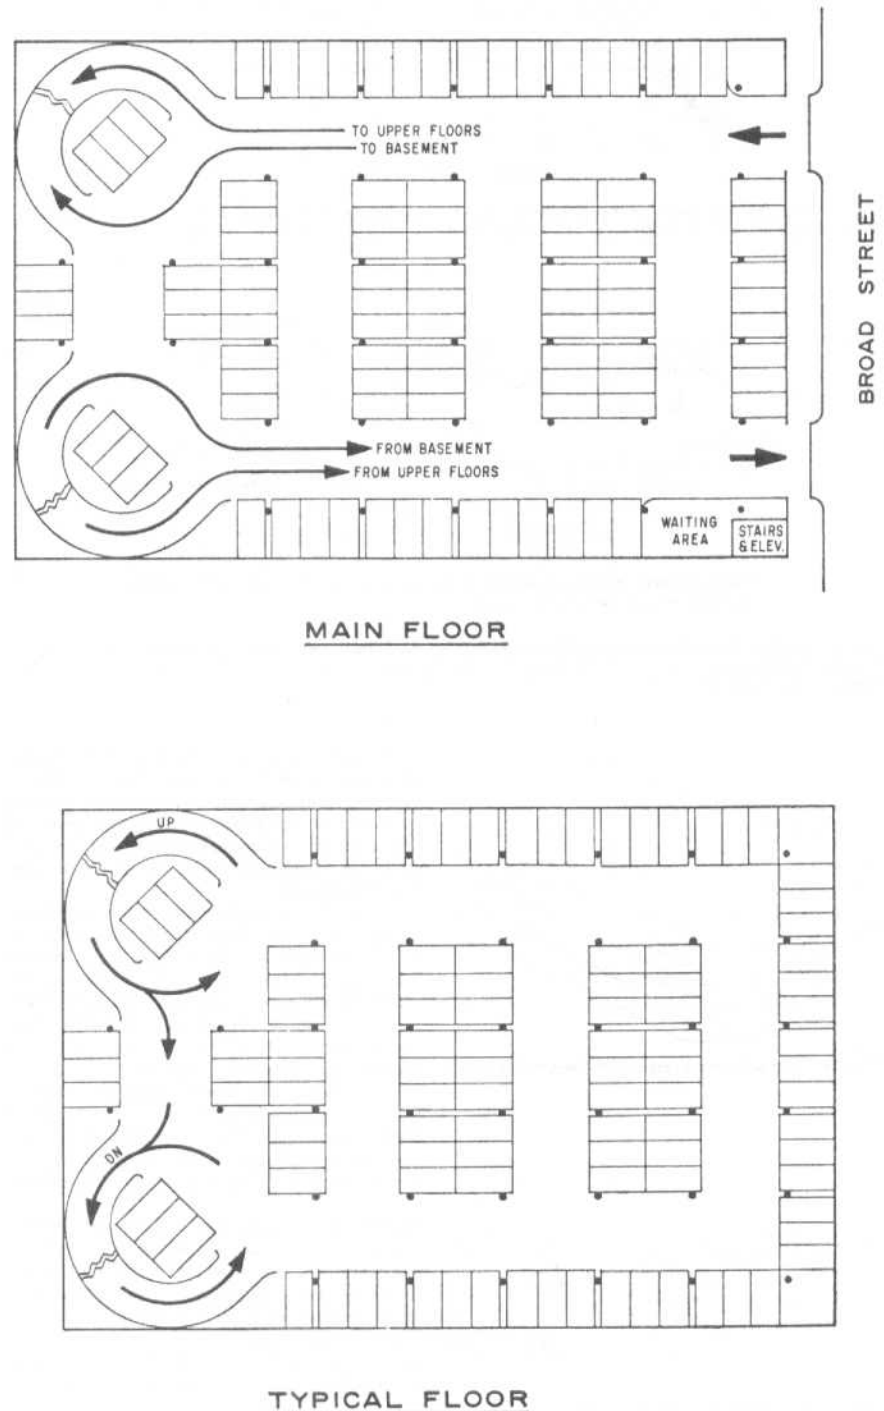

Fig. 1 Functional plan for twin-spiral garage.

PARKING GARAGES

and the stairs and elevators are strategically located in the center of the facility to take advantage of the split-level and to afford minimum walking distances.

In Fig. 3 a functional plan is presented for a facility with straight ramps. The garage has one-way aisles and angle parking. Actually, a portion of the aisles is used in the floor-to-floor circulation. There are three pedestrian elevators and four stairways to serve the eight floors. Though the entrance and exit were on

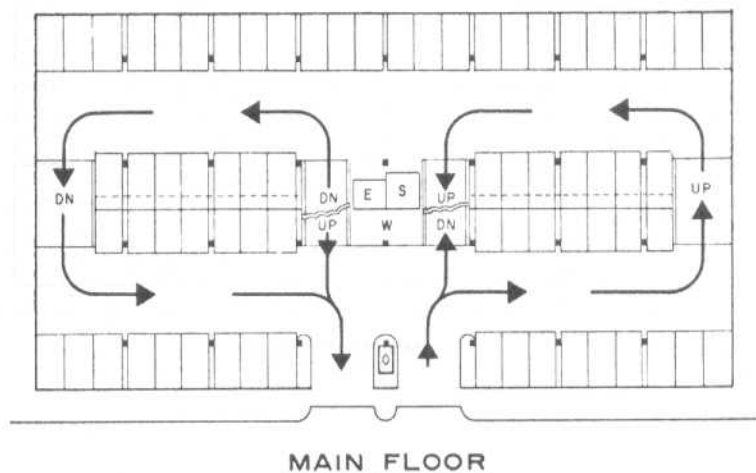

the same street, they are widely separated to reduce conflicts. The overall dimensions of the facility are 183 by 165 ft.

In a sloping-floor or continuous-ramp garage, the aisles serve two purposes: access to the parking stalls, and floor-to-floor circulation. In Fig. 4, a typical garage is shown which provides 90° parking. One pedestrian elevator and three stairways have been provided for the five-level facility. The entrance and exit are on one street. The direction of travel on the

ramps has been reversed to reduce the conflict at the contact with the one-way street. Overall dimensions are 122 by 157 ft.

The preparation of a design for an irregular-shape site presents many problems, especially when self-parking is to be provided. An example of a good design is presented in Fig. 5 where a spiral ramp is in the center of the garage. The aisles are one-way and two-way, and 90° parking is used throughout the facility.

For the three-floor garage, there is one

pedestrian elevator available at present. Plans and areas are provided for an additional elevator when warranted. There are four stairways. In the operation of the facility, an entrance has been provided on one street and two streets are used for exiting.

Many variations may be used in garage design. The previous examples are typical designs. Design criteria and standards were assembled in a recent study.¹ The designs must be tailored to the available land.

By GEOFFREY BAKER and BRUNO FUNARO

RAMP GARAGES

Ramp garages do not simply multiply the parking capacity of a lot by the number of parking levels added. Considerable space on each level will be taken by ramps and circulation ways which must be kept free of parked cars. Only on the uppermost level (or the lowermost in the case of an underground garage) can cars be temporarily stored in the aisles as they normally are in an attendant-operated parking lot.

On a sloping lot, developed with only two or three parking levels, space normally required for ramps may be reduced. By connecting adjacent streets to the different parking levels, the street system is, in effect, incorporated into the garage ramp system.

As most garages henceforth will be designed, we believe, for customer self-parking, we have taken 12 percent (i.e., a rise of 12 ft in every 100, or a 7° angle of slope) as the maximum convenient ramp grade.

Actually public use and acceptance of a ramp slope depends less upon the mechanical power and body dimensions of the car than upon the apparent hazards to the woman driver of steep, narrow slopes, and sharp, blind turns. For her also the terror of coming down a ramp is likely to be greater than that of going up, especially now that so many cars have automatic shifts which prevent them from stalling or running backward on hills.

To make a ramp seem less confined and hazardous, it should be one-way, well-lighted but without distracting glare, and separated from opposing traffic with a wide divider strip. Camouflage painting devices may be used to make the slope appear less steep. Horizontal lines of reference can be obscured with wall stripes parallel to, or at a steeper angle than, the roadway. A long sight line, particularly at the upper end of a ramp, will guard against drivers hesitating. This in turn will increase speeds (without decreasing safety), and so increase the ramp's traffic capacity.

The shallower and longer the ramp, the more space it requires on each parking level. The only exception to this is where the whole garage becomes in effect a shallow-angled ramp, a wide roadway with a line of 90° parking on each side. This spirals up and around in a con-

tinuous line of warped rectangles fitted into the rectangular shell of the building.

The second factor governing ramp length is floor-to-floor height. The smaller this dimension, the shorter can be the ramps. However, the floor-to-ceiling clear height should not be less than 7½ ft, and even this will require many radio aerials to be retracted or tied down at the garage entrance. Thin-floor structural slabs are particularly worthwhile in garage construction.

Each end of the ramp, where it joins the parking level, must be blended into the floor grade over a minimum distance of 12 ft. The sections of a modern car most likely to scrape ground at top or bottom of a slope are the long overhangs in front and rear beyond the wheelbase.

The area required for a ramp system will be most important in determining whether a given piece of land can be profitably developed with a multistory garage structure. A floor-to-floor height of 8½ ft requires a 12 percent ramp 71 ft long (see Table 1). Another 45 ft beyond this will be needed for a reasonably convenient turning radius in circulation lanes on each parking floor.

So the minimum length needed for the simplest form of parking deck, with a straight ramp and on more than two levels, is 90 ft in

in attendant-operated garages will be set by the time required to walk between the furthest parked car and the central interfloor man lift which connects with the entrance check-in point where cars are collected and delivered.

This interfloor communication point should be as near as possible to the centroid of the parking floor. For attendants' average walking speed is found to be 5 ft per second; their driving speed averages 13 ft per second.

The layout of parking stalls should be designed to minimize travel time. One 100 ft of extra travel distance to and from a parking stall will add 7½ seconds to driving time, 20 seconds to walking time, thus reducing each attendant's parking rate by one car per hour. In a large operation with high turnover, this will be revealed by either an increase of labor costs, or by long delays in the delivery of cars to outgoing customers, or by need for a larger reservoir to prevent delay in reception of incoming cars.

For customer-parking garages the same standards of walking distance should apply as in parking lots: a maximum walk of 300 ft from parked car to garage entrance. Most important here is allowance for peak periods of interfloor travel by customers entering or leaving.

TABLE 1 Ramp Length for Straight Ramps (to the nearest foot)

Angle, degrees	Ramp grade, percent	Floor-to-floor height					Split-level floors	
		8 ft	9 ft	10 ft	11 ft	12 ft	4 ft	5 ft
3	5	160	180	200	220	240	80	100

4½	8	100	112	125	138	150	50	63
5	9	89	100	111	122	134	45	55
6	10	80	90	100	110	120	40	50
6½	11	73	82	91	100	109	37	46
7	12	67	75	83	92	100	34	42
7½	13	61	69	77	85	92	31	39
8	14	57	64	72	79	86	29	36
8½	15	53	60	66	73	80	27	33

addition to the ramp length, which will vary according to steepness (see plan, Fig. 3).

Minimum economical width totals 108 ft. And still, with these minimum dimensions, there is a quite uneconomical ratio of circulation space to storage space on each parking floor. Only by enlarging the floor areas, which usually means enlarging the available lot size, can more storage space be served by the same amount of circulation space.

Ramp length, of course, can only be reduced by steepening the ramp angle or reducing the floor-to-floor height between parking floors. The shape of a ramp can be changed and condensed by coiling it into a helix.

Location and shape of the ramp system is particularly important on the entrance floor of attendant-operated garages. The further away the ramp from the street entrances, the larger the reservoir space, and the better the cushion against delay and congestion at periods of peak arrival.

In general, as we have seen above, the larger each parking floor, the more advantageous the ratio between storage space and circulation ways. The upper limit on floor area

In a large garage, customer-operated elevators may be insufficient for these peak periods. Escalators will give much better service under these conditions; but they will probably be justified only in a very large garage.

In a parking garage of three floors or less, stairs are still accepted by the public. It will, however, generally be wiser to fill the top floor with long-term parkers, who (perhaps tempted by lower monthly rates) will be more willing to make the climb.

Types of Ramp Garages

Types of ramp garages vary widely. No one plan is best for all sites or all types of garage. The shape of the lot, anticipated parking demand, whether the garage is to be designed for parking by customers or by attendants, limitations of cost and of structure (particularly if the garage is part of another building such as an office block or an auditorium)—all are important factors when deciding what is the most efficient type of ramp design for the job.

¹Parking, Reinhold Publishing Corp., New York, 2d ed., 1963, by permission of Van Nostrand Reinhold Company.

²Ricker, *Traffic Design of Parking Garages*, Eno Foundation, 1957.

PARKING GARAGES

To improve the ratio between ramp area and parking area, the ramp can be steepened, a one-way ramp can be used for two-way traffic, the ramp can be designed to double as a parking aisle with stalls on each side, cars may be parked in the aisles, and more rows may be double-parked. Every one of these will lower operating efficiency. None of them, except possibly the ramp which doubles as a parking aisle, are even to be considered in a modern customer-parking garage.

All ramp systems except the helical need circulation lanes kept clear on each parking floor for a continuous path upward and downward through the building.

Actually all ramp systems must circle in order to gain sufficient length within the building to go upward at a reasonable slope. In helical ramps this circling is confined to the ramp. In all other types the turning movement (through 360 or 180 according to ramp type and floor layout) is made not on the ramp but on the parking floors. This turning movement can be made more easily on a banked helical ramp than on the flat parking floors.

Minimum site width required for a ramp garage is 100 to 110 ft, as shown below; and even then there is a quite uneconomical ratio between parking area and ramp space. A helical ramp would fit a narrower site but waste even more space. For a narrow site, particularly a corner lot, the elevator garage may be most economical. Minimum width of the structure alone may be as little as 60 ft. But there must be access on both sides of this, for entrance and exit. There should also be off-street reservoir space. So minimum site width, with a street on the front and one side, is 80 ft. (see Fig. 6). If there is no side street, another 20 ft must be added to the frontage for exit lanes.

Fig. 6

Of helical ramp types the least costly to construct is usually that shown in Fig. 7. One-way up and down lanes are on a single-banked surface. The outer lane is used for up traffic, usually counterclockwise, so that cars keep the right in normal fashion.

The diameter of the ramp is controlled by the required turning radius: a minimum of 45 ft to the face of the outside curb of the outer lane. There is crossing of traffic at each parking floor connection, but drivers have a clear view each way.

In the circular ramp shown in Fig. 7 there is no crossing of up and down traffic, even at the parking floor connections. Each traffic stream is confined to its own ramp all the way from top to bottom of the building.

As entrance and exit points are at opposite sides of the ramp cylinder, the best position for this type of ramp will be near the center of the parking floor.

The surface of these ramps can be fully banked between floors, but they must be flattened at the point of connection with each park-

TRAFFIC CIRCULATION ON PARKING FLOORS (BELOW) IS IMPOSED BY THE RAMP LAYOUT CHOSEN

ing floor, so that cars can turn off and on without too sharp a break in grade.

To avoid scraping the floor with front or rear overhangs or some part of the underbody of the car, change of grade between floor and ramp must not be too sudden. The blending

Fig. 7

Fig. 8

Fig. 9

distance must be at least as long as most wheelbase lengths—about 10 ft. As precise construction in concrete is not to be expected, it is wiser to set 12 ft as minimum. A simple rule of thumb is to make this transition grade half the ramp grade. (See Fig. 8.)

Halfway between the circular and the straight ramp is what may be called the rectangular circle. This is so large and so shallow that it normally fills the whole building, and so wide that there is a line of right-angle parking along each side. The floors of the garage become tilted planes. A basic disadvantage of this plan is that a two-way circulation road must also serve as a parking aisle—and a very long one too. The inevitable result is congestion and delay, particularly at the lower levels during outgoing rush hours.

Probably the simplest types of ramp in structure, planning, and operation are the two-way divided ramps set one above the other at one edge or in the center of the parking floor. (See Fig. 9.)

This is quite economical of space, particularly on a lot that is rather long and narrow. Two-way circulation lanes on the parking floor may be hazardous.

Here the up and down traffic streams have been separated. This plan still has the advantages of rectangular shape and small ramp area. But the up and down circulation lanes intersect on the parking floor unless the floor area is so large that each circulation can be kept within its own half on one-way lanes.

Fig. 10

On some sites it may be an advantage to have in and out traffic widely separated at street level, as it is here.

If the up and down ramps crisscross at each floor (like an X in elevation), the two traffic streams flow in the same direction on each parking floor, and conflicting traffic movements are immediately reduced.

By placing up and down ramps at alternate edges of each floor, the up and down circulation in the ramp type shown in Fig. 10 is completely separated. Moreover, the turning movements have been cut in half. The car has to turn through only 180° (instead of 360° as in the preceding ramp plans) to go up or down through one parking level to the next. The travel distance on each floor is also reduced, so this type of ramp layout usually shows excellently fast driving time between floors.

At ground level the in and out ramps point in opposite directions, so this plan is particularly well fitted to any piece of land which runs through a block so that it has frontage on two streets.

The Split-Level Garage

The split-level garage is the parking equivalent of the split-level house. One section of a garage is offset vertically by half a story from the remainder of the building. (See Fig. 11.)

The length of each floor-to-floor straight ramp can then be divided into two halves separated from one another in plan sufficiently to allow a 180° turn on the parking floor. This means a minimum distance of 45 ft center-to-center of the ramps.

Climbing upward, or on the return trip down,

PARKING GARAGES

Fig. 11

the motorist negotiates these short ramps easily, so that parking in a ramp garage seems no more complex or frightening than any other sort of driving.

At the junction point between the two sections of the building, where the floors are offset vertically, they also overlap horizontally. In these few feet along the edge of each floor there is only half the normal floor-to-ceiling height found in the rest of the building; but this is sufficient height for the end few feet of a car, front or rear. So here the parked cars actually overlap one above the other, to give a saving of perhaps four to five feet in the overall width of the structure. On a narrow lot these may be the few extra feet necessary to accommodate minimum parking lot dimensions to the dimension of the lot.

Any of the ramp and circulation systems discussed earlier can be applied to the split-level garage structure.

Mechanical Elevator Garages

Mechanical elevator garages are most suitable on expensive sites which are too small for economical development with a ramp garage. They are the only practical means of developing garage space on deep lots with narrow frontage.

Mechanical elevator garages can be structurally very light and open if local building codes allow.

The two principal makes—Bowser and Pigeon Hole—both impose similar circulation patterns. Cars enter the central elevator hoistway on one side and exit on the other. So this type of garage is particularly well suited to corner sites, or any interior lot where the long side abuts on an alley which can be used for exit. In such cases the main street frontage required will be only 80 ft.

If entrance and exit must be on the same frontage, the minimum width required will be approximately 100 ft. On a structure above 10 stories in height, however, if sufficient reservoir space is provided at ground level to cushion peak arrival periods (without cars having to line up on the street outside), the lot size may have to be greater than this minimum.

Up to a point this will depend also upon the number of elevators used (the more elevators, the higher the speed of storage and delivery),

which in turn will affect the capital cost of such a garage structure.

In mechanical elevator garages a minimum of one quarter of each parking level area is occupied by circulation. When there is no double-row parking (which may entail moving front-row cars to reach those in the back), circulation space, i.e. the elevator hoistway, occupies one third of the area on each parking level. On the other hand, on a site 100 by 100 ft a circular ramp (the most condensed type) would occupy almost two-thirds of the area on each level.

The Pigeon Hole hydraulic elevator equipment moves on rails set on the ground; the Bowser electric elevators are hung from an overhead crane track. In both systems the elevator car moves simultaneously in a horizontal and a vertical direction. This is the all-important difference between these elevator systems and those which proved unsuccessful in the thirties.

Pigeon Hole uses a dolly, controlled by the elevator operator, for moving the car in and out of the elevator. Bowser elevator operators drive the car on and off. The elevator control panel is within easy reach of the operator as he sits in the car. An intercom and signal light system connects the elevators with the cashier's control booth.

The Bowser elevators are counterweighted so that, if the electric power fails, the garage can still be unloaded. These elevators will rise without power when empty. Loaded with a car, they descend at a controlled rate.

By FRANK HARRISON RANDOLPH, P.E., Professor of Hotel Engineering, Cornell University

Parking stalls should be built to accommodate the larger cars frequently used, although not necessarily the very largest. Planning in hopes of just medium and small size cars invites difficulties. The larger cars have an over-all length of 19 ft, over-all width 6 ft 8 in., with a wide open door projecting 3 ft 4 in. beyond the over-all width. The ramp angle must not exceed 7 deg. The limit of the front approach angle is 14 deg, while the corresponding angle at the rear is limited to 9 deg. When parked at right angles to a curb or buffer, the front overhang¹ generally does not exceed 2 ft 10 in., and the rear overhang¹ seldom exceeds 4 ft 6 in. These dimensions need consideration when planning widths of sidewalks affected by the overhang. A 5-ft sidewalk would have its usable width reduced almost to zero by the rear overhang. The front overhang may be taken at 1 ft 6 in. when figuring closely the minimum feasible spacing between buffers for a minimum width parking lot. When a central driveway is used with 90 deg parking on both sides, the space required is 62 ft wide, but the space between buffers need be only 59 ft because of the overhang.

A single stripe, 4 to 6 in. wide, may be used to mark the parking stalls. Better results in centering the car are obtained by using two 5-in. stripes, separated by 1 ft 6 in., to mark the stalls. The stripes, about 18 ft long, are joined by a semi-

¹ Overhang beyond curb or buffer is about 6 in. less than overhang dimensions (see section on "Dimensions") which are measured from the center of the wheel.

circular arc at the incoming end to form an elongated U (Fig. 3). Experience has shown this method to be very satisfactory and fully worth the extra painting.

Parking stalls should be at least 9 ft wide, 10 ft wide if space is not too restricted. Parking stalls 8 ft 6 in. wide are unsatisfactory because with the car 6 ft

8 in. wide, there is only 1 ft 10 in. between cars. If an adjacent car is only 6 in. off center and the car door is 4 in. thick, only 1 ft remains through which to squeeze, if possible.

Motel parking lots planned for maximum guest convenience, mark off parking stalls 11 ft wide and 23 ft long, allowing

Commercial PARKING LOTS

Fig. 2

Fig. 3

4 ft behind the 19-ft car for unloading space which is advisably clear of the driveway.

Parking lots, exclusive of drives for entering them, require 350 sq ft per car as a very rough, preliminary figure. The width of the available space and the desired angle of parking are determining factors in economy. The area per car varies from 279 to 585 sq ft under conditions covered in the tabulation of parking lot dimensions. A central driveway with two rows of cars and 90 deg parking gives the best economy. Diagonal parking is easier for the driver, reduces the necessary driveway width, but requires more total space (Fig. 1).

In designing parking spaces, end stalls should be about 1 ft wider than usual, especially if bounded by a building or other obstruction or a driveway. Parking spaces under buildings should be 11 ft

wide, watching out for columns, and should have 7 ft height in the clear.

The parking pattern that will be most satisfactory fully warrants careful thought. It depends upon many factors including the possible locations of access drives. These should be 20 ft wide for two-way traffic or 12 ft wide for one-way traffic (Fig. 2). If a restricted site frontage requires a right-angle turnoff, the driveway should be 25 ft wide and the curb should have a 30 ft radius. A curb radius of less than 18 ft is inadvisable.

A slope of 6 per cent is the usual maximum for state highways. A slope of 12 per cent is customary for ramps, but may be as much as 15 per cent. The parking lot should be nearly level. The central driveway may be crowned, with a 1 per cent slope draining to the edges so that persons on foot will find the driveway relatively free from water after rain or from ice in winter weather.

AUTOMOBILE SERVICE STATIONS

Fig. 1. Plan of typical two-bay service station building

Drawings show the standard plan of a major oil company for a two-bay service station. Additional bays may be added for larger installations.

Minimum recommended dimensions for bay door opening is 10 by 10 ft. Overhead type doors are the most effective. Servicing pits have become obsolete, the mechanical lift being considered more practical.

Site

The ideal would be a wide, level, rectangular lot on the corner of a primary thoroughfare. If an interior lot must be used, it should have wide frontage for display purposes and sufficient depth for future expansion. While in some cases the suburbs may provide the ideal dealership site, in metropolitan areas with space limitations it may be necessary to plan on expanding upward, by adding levels to present facilities, to relieve growing pains.

Space Allocation

The site selected should contain sufficient usable space to provide for an adequate building and the necessary outside lot area. Ordinarily, the space allocation is approximately 60 percent outside area and 40 percent inside or under roof area. The inside space of a dealership is ordinarily apportioned into four major areas approximately as shown in Table 1.

TABLE 1 Inside Space Proportions

Inside area	Percent total inside space
Service department	70
Parts department	14
Showroom	11
Administration offices	5

These figures are basic averages, and therefore will not be exactly the same in all cases. Slight upward revisions in space allocation should be provided in the service department area for dealerships doing a large service business.

Outside space apportionment generally takes into consideration the requirements for used car display, service parking, new car storage, and employee parking. Space allocation among these four areas varies according to the sales volume set up in the planning potential of the dealership. In general, twice as much space is allotted to service parking as employee parking, and used car display requires roughly twice the space needed for new car storage.

Space Analysis

The illustrated building layout was prepared as an example, in accordance with (Fig. 1) recommendations for a conventional dealership building design. (See also Table 2.)

	Square feet
Total building area	46,200
Showroom and administrative offices	7,200
Parts department	6,500
Service department	32,500
Number of service stalls	66

Planning Potential

A dealership's planning potential is a reasonably expected annual new car sales potential, which a properly located dealership with adequate facilities, and effective manpower and management, should be expected to retail profitably over the business cycle. Planning potential is a measure of the sales potential, based on the actual high price group market within the dealership's area of sales responsibility and, as such, is not necessarily a measure of the dealership's past or expected retail unit sales performance. It is against this planning figure that space guides are recommended.

SHOWROOM

The new car showroom performs a merchandising and advertising function for the entire dealership. The exterior should be designed, decorated, and lighted so it will stand out from its immediate surroundings in an appealing way as well as identify the business quickly and be inviting to potential customers. It represents the basic physical image of the dealership as it first appears to the customer, influencing not only his original valuation of the facility as a place of business but also his continual impression of it. It exerts an immeasurable but certain pressure on owner relations.

Locating the Showroom

The showroom should be located in a position of unobstructed visibility—one that will readily attract the attention of people passing by. It should present at a glance an impressive and appealing view of the new cars on display. If the building site is on a corner, the showroom should be on the corner facing both streets for maximum visibility of its interior. On an inside lot the showroom should be projected in front of the major portion of the facilities to increase visibility and exposure time. Always provide maximum customer visibility.

Additional new unit display, if desired, can be provided outside the showroom under a canopy or roof extension, adjacent to the customer service reception area or through use of a landscaped patio display area. These types

AUTOMOBILE DEALER CENTERS

of new unit display areas are relatively inexpensive to provide and can be very effective.

The minimum space guide for inside showroom display is 500 square feet per unit. Leave at least 5 ft open around each car. This will allow space so that the customer may walk around and open the hood, doors, and trunk freely. Allow as much extra space as possible around the display, so that customers can stand back and get a good view of the car from all angles (Fig. 2).

OFFICES

Location

Most dealers have their own preference for the location of offices. As a general rule, the office of a department manager should be placed close to the activities of his department (Table 3).

TABLE 3 Average Office Size

	Average size, ft	Area, sq ft
Dealer	12 by 15	180
General manager	12 by 15	180
Sales manager	10 by 12	120
Owner relations manager	10 by 12	120
Truck manager	8 by 10	80
Used car manager	8 by 10	80
Sales closing office	8 by 8	64
Men's and ladies' rooms	8 by 8	64
Meeting room	20 sq ft per person	
General office	100 sq ft + (60 sq ft x number of office employees)	

Additional consideration should be given to the following areas: waiting room, janitor closet, walk-in vault, file and record rooms, telephone equipment room. Sizes of these rooms should be in accordance with individual requirements. If vending machines are considered, install them in the service area near a waiting room.

General Offices

The general office should be in a central location, convenient to all operating departments, with adequate lighting, heating, and cooling for maximum productivity.

The size of the general office is determined by the number of employees and the amount of office equipment. Sufficient space should be provided for the storage of stationery, office supplies, and promotional literature.

Vault

A built-in vault adjoining the general office is customary for storage of valuable documents. If this is not possible space should always be provided for fire-resistant equipment to protect important records (Fig. 3).

SERVICE DEPARTMENT

Just as capacity is the key to profitability, overall organization and appearance determines the operating efficiency and sales appeal of the service department. Dealers have to create a balanced service environment that serves

Fig. 2

the customer's needs as well as the dealer's. The service department is a "salesroom" for service and should be treated as such.

Basic Considerations

The following are features that should be considered basic elements in the service environment: the covered, out-of-the-weather reception area, well-positioned signs that spell out traffic flow, the service tower that provides visual control, including a view through the service entrance and into the street and over the reception area and into the work areas, the customer lounge and cashier at one location, convenient access to the lounge without the need to wander through the service department to find it, wide entrance and exit lanes, and uncrowded write-up areas with sufficient room for customer convenience.

The type of building shown in Figs. 4 to 6 requires 120 sq ft per stall for access area which results in an average of 420 sq ft per stall. (Work area plus access area.) An average of an additional 80 sq ft per stall is required for other nonproductive service-related areas such as a tool room, locker room, service manager's office, and other utility areas. This results in an average area requirement per stall for a conventional 70-ft (inside dimension) center-aisle type of building of 500 sq ft per stall.

The space and stall needs of the service department are determined by expected business. However, the size and shape of the lot and building will sometimes dictate the service department general layout and arrangement. For best efficiency, a service building width of 70 to 72 ft is suggested. It is wide enough for two rows of cars and an aisle, and can accommodate a few truck stalls. For two rows of work stalls and an aisle, the 70-ft width is considered an absolute minimum.

A width of 80 ft is recommended if the dealer specializes in truck service and does not want a building with direct drive-in stalls. Recommended width for a building with a single row of direct drive-in stalls is 30 ft for passenger cars and 35 ft minimum for trucks. Recommended width for buildings with a double row of direct drive-in stalls is 60 ft for passenger cars and 70 ft if exclusively used for

trucks. Recommended width for buildings with two rows of stalls, an aisle, and a 30-ft extension on one side, with direct drive-in stalls, is 100 ft. Recommended width for buildings with two rows of stalls, an aisle, and a 30-ft extension on each side with direct drive-in stalls is 130 ft.

Customer Reception

The reception area should be immediately inside the service entrance, decorated, well lighted, and equipped to create the best possible impression and selling atmosphere.

It is strongly recommended that the customer reception area be removed from the productive service area. This concept has the following advantages: (1) keeping vehicles out of the productive area until they are ready to be worked on; (2) outside (canopy) recep-

AUTOMOBILE DEALER CENTERS

tion area can be considered, which is less expensive than inside roof area; and (3) customers prefer a clean, quiet atmosphere to the normal noise, dirt and congestion of the shop area.

Straight-through reception area is preferable and more conducive to service selling. Traffic control also is much more efficient, with congestion and car maneuvering kept to a minimum.

Where local climate permits, outdoor covered reception areas may be desirable as a building economy. The outdoor reception area can be designed to attractively complement the building architecture.

Customer Waiting Room

A special waiting area should be provided for customers who wait for service repair on their cars. Comfortable chairs, table, T.V., and a public telephone are desirable. Some dealers provide a waiting area in the showroom. However, a separate room, near the customer reception area and cashier, is desirable. The room size will be determined by the potential business.

Doors

The service entrance door for the customer reception area should be 16 ft wide and 12 ft high. A two-lane traffic door should have a minimum width of 24 ft. Wide doors make it easier to move cars into the stalls just inside the service entrance. Single service exit doors should be 14 ft wide and 12 ft high.

Service Control (Tower)

The service control tower should have sufficient space for efficient operation and the necessary equipment to control and schedule the service.

Write-up Area

The write-up desk adds a professional touch to the service selling function. It is desirable to have the desks located on the driver's side of the car entering the reception area.

Traffic Flow

The layout of the service department should be planned so that entrances and exits permit one-way traffic flow. Traffic flow should be a combination of dealership aisle patterns coordinated with traffic movement on public streets and alleys.

The arrangement of stalls to obtain an efficient

traffic pattern is one of the most critical factors in planning an efficient service department.

Stall Arrangement

Productive stall arrangement depends on size of operation, number of specialized technicians, and the dealer's preference. However, here are a few fundamentals to keep in mind—convenient location of entrances and exits, easy access to quick service stalls from customer reception area, parts counter convenient to lubrication and quick service stalls, separation of body shop, and maximum efficiency of aisle space by having one access aisle serving two rows of productive stalls (Fig. 7).

The standard 70-ft-width pattern shown in Fig. 8 provides the most efficient use of covered service space when an aisle is required. Long and narrow, it works best in small and medium-size operations. With only two main doors, heating costs are low; and when land is ample, expansion is simply a matter of adding on—without the need for major structural work.

However, if the number of stalls needed results in an excessive overall length, it makes supervision difficult and places many stalls too remote from the parts department.

Service facilities with a high percentage of "fast-in—fast out" customers find the T pattern efficient. Notice that the write-up area does not conflict with the productive stall traffic flow area. Cars can be moved directly into stalls—or optionally, straight through to the service parking area, ensuring one-way traffic flow. Clear-span width is 70 ft. Like the I pattern, expansion is relatively simple (Fig. 9).

With doors on one side, it is suggested that the building should be 30 ft wide. With doors on both sides the recommended width is 60 ft. Direct drive-in stalls provide a maximum number of stalls in a minimum floor area and are very economical to construct. Although these buildings occupy less space than the 70-ft-wide buildings, they require more space on the lot for service drives and entrance to the building. The 60-ft-wide building is ideal for truck service because each double truck stall can accommodate the largest bus or tractor-trailer. Often a combination of a 70-ft-wide building with 30-ft extension on one or both sides can be used very advantageously. The larger span of the roof beams can be 70 ft because the necessary columns do not interfere. This creates a double row of stalls on each side of the central aisle. The cars in the 30-ft extension enter and leave through overhead doors in the side of the building. Here the double stalls can be used for servicing buses or tractor-trailers and, if there is a double wash rack, it

can be used for washing these large vehicles (Fig. 10).

Stall Dimensions

The width of stalls is made up of "car width" plus working space on each side of the vehicle. The total width varies from 10 ft to 14 ft according to stall function (Table 4).

Whenever a stall is next to a wall, add 2 ft to its width. Local building or fire codes supersede these recommendations if they conflict.

TABLE 4 Stall Dimensions

Stall function	Width, ft	Length, ft
Customer reception (aisle)	14	25
Lubrication (overhead equipment)	12	24
Mechanical repair	12	24
New car conditioning	12	24
Polishing and sheet metal	12	24
Paint spray booth	14	28
Wash rack	14	25
Parking	10	20

Service Stall

General-purpose service stalls should be 12 ft in width. In special situations, an 11-ft width may be acceptable, but only when structural requirements or land limitations impose the need. In buildings with direct drive-in stalls, 12-ft widths are mandatory, since lack of an aisleway means minimum walk-around and working areas. Figure 11 provides general dimensions and locations for equipment.

If the work load is light and space is at a premium, a single-stall station might be appropriate. In this suggested layout (Fig. 13) the brake testing is done on the road. Wheel alignment, front suspension hoist or jack area, and headlight testing and aiming are provided through careful arrangement in a single lane. This could be either a drive-through or drive-in-and-back-out system.

The drive-in-and-back-out safety test area could be designed around an existing front-end pit. Wheel alignment and under-vehicle inspections are made in one lane and visual inspection, brake testing and headlight testing in the other. Suggested layout could possibly be realized by the relocation of existing equipment (Fig. 14 and 15).

AUTOMOBILE DEALER CENTERS

I PATTERN

As shown in the illustrations, a simple "I" pattern is the most efficient. This will work in most dealerships if the site permits such an arrangement. However, it cannot be considered a "cure-all." If the number of stalls needed results in an excessive overall length, it makes supervision difficult and places many stalls too remote from the parts department.

T PATTERN

The "T" pattern permits the same number of stalls as the "L" pattern. However, it is not suggested over the "L" pattern since it makes car movement difficult into the two end stalls near each exit. This stall and aisle pattern is useful in cases where an exit in the rear wall is impossible and the location of an alley makes two side exits more practical.

L PATTERN

The "L" Pattern is the second most efficient stall and aisle arrangement. It is normally used in those instances where straight through traffic is not possible. Note: it is necessary to sacrifice two stalls in order to accommodate one of the entrances.

U PATTERN

The "U" pattern is used in large service operations or where no other arrangement is permissible because of existing neighboring structures or public streets. The "U" tends to centralize service traffic for more efficient control and accessibility to supporting departments.

TRUCK DEALER AND SERVICE FACILITIES

AREAS

New Truck Display

Truck sales profit from good interior display, particularly light-tonnage trucks sold to families as second cars or recreation vehicles.

However, because of the wide variation in size between truck models, and because the sales of larger units are frequently made away from the dealership, indoor truck showroom displays are usually limited in size.

If you plan an interior display area, make sure that it is large enough for at least one pickup, with adequate room to walk completely around it (1,000 sq ft). The display should occupy at least 3 percent of the dealership's total area.

The display should face the majority of traffic that moves past the dealership, and be placed so that a driver does not have to turn his head to see it.

For a driver to see a display easily, it should be within 30° to the left or right of his straight-ahead forward vision, and close enough to catch his eye.

Display area windows should be large, but do not have to be slanted. Having strong enough lights inside the display area will usually minimize any natural glare or reflections on the outside of the glass.

Many truck dealerships rely entirely on exterior display.

This may be under a canopy or not. The advantage of the canopy is that the vehicle stays cleaner longer, doesn't spot as easily from rain or snow, and is sheltered from the sun and weather.

The disadvantage of the canopy is cost and the fact that vehicle movement can be hampered if the placing of the canopy supports is not carefully planned.

Private Offices

The dealer's or general manager's office should be the largest in the dealership.

The office should be able to accommodate four or five visitors. It should have closet and storage facilities, and if desired, its own men's room.

Consider the possibility of allowing this office to double as a meeting room for the sales staff (Table 1).

If the dealership also has a sales manager, he should have an office.

Offices for individual salesmen can double as closing rooms.

Meeting Room

A meeting room is not a luxury in a truck dealership.

When facilities have lunchrooms, these are frequently used as meeting rooms.

If it's not possible to have a separate room for meetings, consider installing a folding wall between two small private offices so that they

can be opened up into a meeting room. Or consider using the dealer's office for a meeting room.

Wherever the meeting room is, it should be possible to darken it so that pictures can be projected.

Equipment for 16 mm motion pictures and 35 mm sound slidefilm projection should either be permanently set up or be stored in a convenient cupboard. A blackboard and/or chart stand will also be useful.

General Office

If the cashier works in the general office, then the office should be adjacent to the parts counter and the service reception area, so that the cashier's window can serve both.

The general office should be furnished with adequate desks, chairs, files, business machines, and other equipment.

It should be comfortable, reasonably quiet and well lighted.

Storage should be provided in the room for current operating records and daily supplies. Old records and infrequently used supplies can be stored somewhere else.

Vault and Storage

A vault should be provided for cash and valuable business records. If no vault is provided, essential records should be kept in special fire-resistant files or fireboxes.

Stationery, sales promotion material, model literature, and seasonal dealership decorations should be given a storage area. Obsolete records can also be stored here. This space can be in a basement, mezzanine, or on the same floor but in an out-of-the-way location.

Rest Rooms

Rest rooms for men and women employees and for customers should be provided. While local codes will dictate much of the design and equipment for these rest rooms, try to select durable and economical as well as attractive fixtures.

Floor Plan

The most functional type of layout for a truck service department is one with drive-through stalls (Figs. 1 and 2).

Trucks of varying lengths can be easily handled, including those with extremely long wheelbases. Each vehicle can be moved in or out without disturbing the others. And since no aisles are required, more floor space is useful space.

The two things that can prevent the use of this kind of stall are climate and a narrow property with limited turn-around space outside.

Where the climate is extremely cold, drive-through stalls can be too drafty and too expensive to heat.

Where there is not enough room outside for vehicles to move freely at both sides of the building, such as at some in-town locations, drive-through stalls are impractical.

However, a practical layout in this situation would be stalls where you drive in and back out through individual doors.

To preserve heat in very cold areas, it may be necessary for the department to use a common entrance door, with the trucks turning into individual stalls after entering the building. If these stalls are angled, more floor space will be required for each stall, although less will be required for the aisle.

TABLE 1 Sales Area and Building

Area	Space allowance
Interior display	
Showroom	1,000 sq ft, plus 600 sq ft for each vehicle over one
Entrance door	10 by 12 ft (pickups) 12 by 14 ft (larger trucks)
Offices (minimum):	
Dealer or general manager	180 sq ft
Sales manager	120 sq ft
Salesmen	90 sq ft per man
Closing office	64 sq ft
Used truck office	120 sq ft
General office	100 sq ft per person
Ceiling height	Offices—9 ft 6 in.
Meeting room	Allow at least 12 sq ft for each person to attend meeting, plus room for speaker and for projection equipment
Other areas:	
Rest room	30 sq ft minimum
Hall or aisle	5 ft wide
Janitor closet	32 sq ft minimum with deep sink
Customer's waiting room	Variable

Profitable GMC Dealership Expansion, General Motors Corp., 1967.

TRUCK DEALER AND SERVICE FACILITIES

Fig. 1 Layout for small dealer.

One-way traffic through a service department door is more efficient than two-way traffic. If a common entrance must be used, try to provide a common exit at another point.

FLOW FACTORS

Four groups of things move or "flow" through the department while it is working.

How logically and easily each of these groups flows determines much of the department's ability to make money.

The four flow factors are:

1. Flow of traffic
2. Flow of people
3. Flow of parts
4. Flow of repair orders

Flow of Traffic

Start by planning where the customer traffic will wait before it gets to the service salesman or write-up man.

There must be adequate standing room outside where waiting vehicles will not get in the way of other dealership customers or street traffic.

From the service salesman, traffic must flow either to another waiting area, or to a stall where work is to be done.

If the vehicle will have to go to more than one stall (such as from diagnosis to a work stall) it should never have to backtrack.

When the work is done, the vehicle should move out to be road-checked by dynamometer and parked.

Before you approve of any service department layout, mentally move a day's traffic through it to see where the bottlenecks appear.

Flow of People

The customer should be able to get out of his vehicle, talk with the service salesman, go to the driver lounge or out of the dealership, go to the cashier and pick up his vehicle without getting in the way of sales, service, or parts employees.

The mechanic should be able to get the tools and parts he needs without going through customer areas or getting in the way of other workers.

Flow of Parts

Parts shipping and receiving should not have to be made across the flow of incoming service traffic. Parts customers should not have to wait for service customers.

Parts access for the service department should be convenient, both for the mechanic and for the parts department. To get parts, the mechanic should not have to travel far or travel through customer waiting areas. Departmentally, quick service and tune up stalls should be nearest the parts counter.

Stalls doing work that normally requires fewer parts per day (such as heavy repair) should be farther away than stalls doing general repair and maintenance.

Flow of Repair Orders

Trace the physical movement of repair order originals and copies in your current maintenance system.

Bad flow here will cause wasted mechanic time, slower billing with increased customer dissatisfaction, poorer cost accounting and maintenance control. In larger buildings a system of pneumatic tubes between offices aids in the efficient flow of paper work.

ROOMS AND AREAS

Service Manager's Office

The service manager's office should provide privacy and relative quiet, so that it can be used to handle customer complaints.

It should be closed off from the working area to keep out dirt as well as noise.

It should have windows and be located so that the service manager can easily see the main service entrance and the work areas of the department that return the highest profit.

Direct supervision from the service man-

ager's office improves work quality and reduces idleness.

Being able to see diagnosis and service stalls usually improves profit and promotes better care of the special equipment used.

In large operations, a raised office that allows the service manager to look across the entire department is effective.

General Service Area

The number and type of stalls are determined by the services (Tables 2 to 4).

Quick Service Area

Quick service is normally limited to jobs that can be done in one hour or less.

An area set aside for quick service usually produces more profit per square foot because it creates a high parts volume with relatively short labor times.

Specific quick service jobs fall into these areas:

Engine tune-up	Wheel bearings
Cooling system	Shock absorbers
Exhaust system	Universal joints
Adjustments:	Electrical
Clutches	Tires
Brakes	Lubrication
Transmissions	Body
Front end	Trim
Brake linings	
Wheel balance	

Quick service can be done in a limited way in any service operation, just by setting aside a stall for that purpose. However, the most profitable quick service results from using special methods, tools, and equipment; also in reducing the time required to get parts.

Unit Repair

A separate unit repair room can speed the rebuilding of engines and other assemblies. This room is usually most effective when separated from the general repair area. It also has all the necessary tools and equipment for

TRUCK DEALER AND SERVICE FACILITIES

TABLE 2 Service Areas*

Area	Space allowance or dimensions
Service manager's office	Usually 120 sq ft
Paint department office (if separate)	Usually 120 sq ft
Driver's lounge	100 sq ft plus 20 sq ft for each person over 5
Lunch room	300 sq ft plus 20 sq ft for each person over 10
Showers, rest rooms, lockers	60 sq ft plus 10 sq ft for each man over 5
Unit repair	Minimum of 300 sq ft
Detroit diesel injector repair	Minimum of 48 sq ft
Toro-Flow diesel fuel pump	Minimum of 80 sq ft
Entrances:	
Individual service doors	12 ft wide, 14 ft high
One-way main service doors (or reception door on drive-through layouts)	16 ft wide, 14 ft high
Two-way main service doors	24 ft wide, 14 ft high
Ceiling height:	
General service area	15 ft minimum—floor to roof truss clearance
Over lifts	17-18 ft
Center aisles:	
With 90° stalls	22-24 ft wide for small trucks only 26-28 ft wide for large trucks
With 60° stalls	25 ft wide for large trucks
With 45° stalls	23 ft wide for large trucks

* The entire service department normally occupies 65 to 70 percent of the total area of the dealership building.

overhaul of units. As a result, the work done there usually produces more reliable assemblies.

By having repair stands, test equipment, and special tools in one location, close to the parts department, a specialist can do the required work in the least time.

The unit repair area should be set off from the rest of the department by wall or screen fencing. It should have a lockable door or sliding 6-ft gate.

Injector Repair

Where frequent Toro-Flow or GM Diesel work is available, a diesel injector and fuel pump repair room is profitable (Fig. 3).

Since this precision work must be done in a dirt-free area, the room must be completely enclosed, easy to keep clean, and pressurized slightly to keep outside dust from seeping in.

Smooth-surfaced walls, windows with flush sills, and benches enclosed to the floor reduce dirt traps and the time required to clean the

TABLE 3 Stall Dimensions

Drive-through type building			
Stalls		Dimensions	Total
Two deep (70-ft building)		15 by 35 ft	525 sq ft
Three deep (80-ft building)		15 by 26 ft	390 sq ft
Three deep (90-ft building)		15 by 29 ft	435 sq ft
Drive-in type building			
Stall angle	Dimensions	Aisle width	Total
90°	15 by 35 ft	28 ft	945 sq ft
60°	17 by 35 ft	25 ft	1,020 sq ft
45°	21 by 35 ft	23 ft	1,218 sq ft
Other areas		Dimensions	
Front-end stalls		20 ft wide, 35 ft long	
Wash rack		20 ft wide, 35 ft long	
Lubrication stalls		20 ft wide, 35 ft long	
Dynamometer stalls		20 ft wide, 35 ft long	
Paint preparation, drying, and cleanup stalls		18 ft wide, 40 ft long	
Sheet metal and body repair stalls		20 ft wide, 40 ft long	
Paint spray booth		20 ft wide, 40 ft long	
Floors.		6-in. wire-mesh-reinforced concrete slab. Compressive strength of not less than 3,000 psi at 28 days. Exposed floors should be treated with floor sealer. Floor should slope ¼ in. per foot toward drain.	
Compressed air lines and fittings		Designed for operating pressure of 175 lb	

TABLE 4 Parts Areas and Dimensions

Area	Dimensions
Parts office	120 sq ft minimum
Parts lobby	200 sq ft minimum
Customer counter	42 in. high, at least 12 ft long
Mechanic's counter	42 in. high, at least 5 ft long
Storage and obsolete files	100 sq ft minimum

Fig. 2 Layout for medium-sized dealer.

TRUCK DEALER AND SERVICE FACILITIES

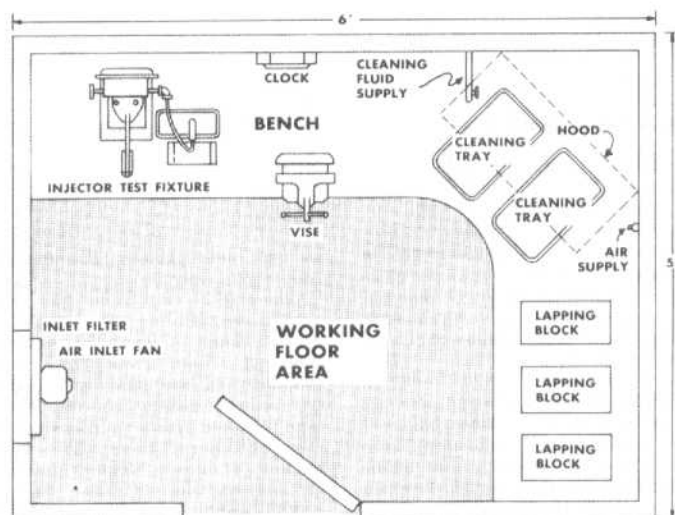

Fig. 3 Typical fuel injector repair room.

room. Light-colored wall enamel also improves illumination.

To pressurize the room, use a fixed fan to draw air in through a glass fiber filter, such as those used in many air conditioners.

To let air out of the room, a hood and stove-pipe with damper can be placed over the solvent pans. This will carry out solvent fumes as well. Or a roof fan can be used to exhaust air that is drawn in through filters placed at opposite ends of the room.

The room also requires an air supply to dry injector parts. The air filter and moisture trap for the air line should be placed outside the room.

Body and Paint Shop

A well-managed truck body shop will usually produce more profit per dollar invested than the dealership's general repair area.

Consult local paint and equipment companies for advice on the best possible layout for the equipment to be used and the services to be offered.

Local codes strongly govern what you can and cannot do.

If possible, plan to separate the body and paint shop from the main service building. This way you avoid the excessive noise, fumes, display of damaged vehicles, fire hazard, and increased fire insurance premiums that can come from an attached body and paint department (Fig. 4).

If the department has to be under the same roof, it must be isolated from the main service area by a firewall.

At least four stalls should be planned for complete body work: one for sheet metal repairs, one for heavy metal work and straightening frames, one for painting, and one for drying and cleanup.

Whether the body and paint shop is attached or separate, an isolated fireproof room for paint storage and mixing will lower insurance costs.

In a separate facility, you will also need to provide office space, wash-up areas, and storage for body parts.

Proper placement of the paint spray booth is a job for an expert. The booth cannot function satisfactorily if the filter doors open directly to the outside of the building. A booth exhausts 7,000 to 14,000 cu ft of air a minute. This air can't be reused because it contains volatile fumes. It must be replaced without creating a draft through the body department. Consult an expert.

EQUIPMENT

Monorail

A monorail is helpful in moving engines and other major truck components to and from the steam clean area and unit repair room.

You can't depend on a monorail alone for engine removal, since it can lift only vertically, and many truck designs require several lift positions to get the engine out.

Minimum capacity for a monorail should be 3 tons. The rail should be suspended from the ceiling structure 20 to 25 ft inside the service

Fig. 4 Typical auxiliary paint and body shop.

doors on a drive-through layout, or near the front of a row of drive-in-back-out stalls.

One end of the rail should be in the wash rack and the other end in the unit repair area.

Hoists

Modern large truck dealerships are using hydraulic floor hoists extensively for quick service and general repair services since their use improves mechanic efficiency and morale. Hoist work also helps attract the best grade of mechanic to the business by providing better working conditions.

Where hoists are used, the best choice is one of the disappearing types. This way a creeper can be used in the stall when the hoist is not being used.

Most mechanical truck services can be provided without the use of hydraulic hoists.

Transmissions and power train components can be repaired with the truck front or rear axles up on stands. To get the unit onto the stand, a fork lift, an A-frame hoist, or a boom lift can be used. The major advantage is that all of these are portable and can move from stall to stall.

Since there is generally ample room underneath most large trucks, work may be done without any lift at all. However, hydraulic lifts can be highly advantageous.

Dynamometer

Any dynamometer needs to be isolated with sound-deadening material because of engine and tire noise.

Fork Lift

A fork lift can be a good investment for the service department and the parts department.

In the service department, it can be used to remove and install heavy truck components and to carry them to repair and cleanup areas.

In the parts department, it can be used to carry large items such as transmissions and for the shipping and receiving of stock.

The fork lift should have an 11-ft vertical beam and a capacity of at least 3 tons.

By JOSEPH HOROWITZ, P.E., Manager, Planning & Design, Facilities Engineering Department, Columbia Broadcasting System, Inc.

I. PLANNING RADIO STUDIOS

A. Scope

This article deals with the planning of radio studios using the term *studios* in the broad sense of facilities for the origination of radio programs. Broadcasting facilities intended for police or other radio communications are not included. Application of broadcasting equipment to stadiums, arenas, concert halls, etc., is a specialized topic and will not be covered here.

Discussion will center on planning an individual station, which may be commercial or noncommercial, but principles are also applicable to centralized network facilities. Except as otherwise indicated, criteria apply to both AM and FM facilities.

B. Planning Factors

Planning of a modern radio station, while constrained by the technology of broadcasting, is determined to a large extent by the station's operating practices. It is essential to realize that, while all stations perform the same basic functions, there are wide divergences of operating practices and philosophy. Planning, therefore, starts with a careful analysis of the station's method of operation.

Following is a checklist of basic planning factors which must be known or established in order to plan the facility.

1. Type of Programming The most important single influence on facility requirements is the type of programming. In current practice this will usually consist of one or more of the following:

- Music
- News and public features
- Interview and panel discussion
- Production of advertising commercials

Some stations may have special requirements for dramatic or audience participation shows, but this is no longer common. Recently, many music-oriented stations have adopted automation, which means, basically, that not only the music but announcer's commentary, time checks, station breaks, etc., are all pre-recorded and all switching is handled automatically. This has significant impact on both layout and power requirement. For all stations an important planning question is the extent of "live" versus recorded programming.

2. Hours of Operation Stations are restricted by their FCC license provisions. Commercial stations must provide certain minimum hours of operation daily.

3. Relationship to Talent Sources The term *talent*, as used here, refers to the persons who participate in programs, whether as performing artists, employees, interviewees, etc.

4. Relationship to Public Some stations view themselves as a kind of program "factory" and limit visitors to persons having specific business with the station. Others encourage visits

from schools and community groups and make elaborate provisions for them, such as viewing windows from which visitors (or passers-by) can view station operations. This decision affects circulation patterns, support facilities, and security provisions.

5. Government Regulations All stations are licensed by the Federal Communications Commission, whose very detailed regulations influence every aspect of operation and hence planning. Regulations, which require constant monitoring of certain devices, influence the configuration of the control room. Most stations are familiar with these requirements, but for a new station, use of an outside consultant may be desirable. As an example, an FCC regulation requiring separate AM and FM programming has generated the need for FM program facilities separate and, in some cases, apart from the AM facilities in some stations that were formerly combined.

6. Emergency Broadcasting System (EBS) Another area of government involvement is the Emergency Broadcasting System. Stations which agree to membership and are designated as primary EBS facilities must provide facilities capable of operation during an emergency. Government financial assistance may be available for equipment and nuclear fallout protection for the emergency studio as well as for emergency generators.

7. Relationship of Studio and Transmitter Facilities Studios and transmitter may be at the same or separate locations. Similarly, stations (such as an AM and FM) may share certain facilities.

8. Operating Procedures Most larger commercial radio stations are highly unionized. Work rules vary from one locality to the next and can have significant influence on planning of studio facilities. In some locations a disk jockey may actually operate the tape player or turntable. In other areas, this work requires a studio engineer or even a separate "platter spinner." Where regulations are less restrictive, one man may act as engineer and announcer if he meets the licensing requirements. In all cases, a careful study of operating procedures is essential.

C. Site Selection

Modern broadcasting facilities are usually quite compact and are often located within a building having other primary functions, such as an office or school. Following are some of the factors to consider in selecting a site.

1. Location Location is largely a function of planning factors 1, 3, and 4, that is, type of programming, relationship to talent sources, and relation to the public. If extensive interviews or panel discussions are planned, the station should be convenient to the prospective participants (show business personalities, sports or government figures). Where the station desires maximum exposure to the general public, it should be easily reached by public transportation. Sales activities of com-

mercial radio stations likewise point to a "downtown" location.

Where these factors are less significant or good transportation is available, advantage may be taken of lower-cost suburban areas. Where studio and transmitter are combined in one building, the technical requirements of transmitters will govern the site selection. (See separate article on planning radio transmitter facilities.) This arrangement, while economical, creates a location conflict, at least for AM stations, since the ideal site for an AM transmitter is rarely convenient as a studio location.

2. Environment Although studio design can compensate for a hostile noise environment, reasonable freedom from excessive noise and vibration is desirable. Within a building, the area selected for studios should be free of overhead building pipes and ductwork to prevent noise and water leaks. It should also have adequate headroom, both for acoustic purposes and to accommodate air-conditioning ductwork. Surrounding tenancies should be free of objectionable noise. Otherwise, environmental factors are similar to those for an office.

3. Utilities A reliable power source and access to telephone and telex communications lines are essential. See Section F 3 for other communications.

4. Parking See Section D 5 (c) for possible parking requirements. Parking (or garage space) for station vehicles used for "remote" (off-premises) broadcasting is particularly important. Desire for liberal parking facilities may conflict with the need for a "downtown" location convenient to visitors, talent sources, and VIPs.

D. Description of Facilities

1. Types of Facilities Radio broadcasting (studio) facilities may be considered under the following groups:

- Technical (on-air) facilities
- Other broadcasting facilities
- Support facilities
- Personnel facilities
- Facilities for off-premises operations

2. Technical (On-Air) Facilities The on-air facilities include the studios and control rooms that form the heart of the station's operation.

a. Studios. A studio is any room used for originating broadcast material—one in which there is a live microphone. With proper acoustical design, studios can be made just large enough to contain the desired number of persons. A two-man studio (disk jockey, newscaster) is shown in Fig. 1, and Fig. 2 shows an interview studio. In contemporary radio, music is almost always prerecorded, and broadcasts involving the public are likely to be recorded off-premises at theaters, concert halls, legislatures, etc. For these reasons large studios suitable for music or audience participation are not required in the station itself. In the exceptional case of an audience studio, the room would be designed primarily as a theater

Fig. 1 One- or two-man studio (newscast, disk jockey, etc.).

Fig. 2 Interview studio.

or auditorium with provision for taping or live broadcasting. This would be a facility apart from the radio station.

Floor areas may range from 100 sq ft for the minimum studio (news, recorded music) to 270 sq ft for a six-person studio suitable for panel discussion.

b. Control Rooms. The control room, as the name implies, contains a control console and other electronic equipment for monitoring and controlling the output from a studio. In addition, it may house tape players, turntables, and automatic switching devices as well as a small amount of disk and tape storage. Plan dimensions are dictated by the equipment to be used; occupants are one or two persons. Figure 3 shows some of the devices that may be contained in a well-equipped control room.

Many smaller stations have so-called "combo" operations, in which the engineer doubles as announcer, disk jockey, etc. In this case, the control room is also a studio and has the same sound requirements. Even when the control room does not contain a live microphone, sound characteristics are still important. The technician monitoring the program must make critical decisions based on what he hears from the loudspeakers, and any distortion caused by room acoustics will be reflected in improper adjustment of controls.

c. Equipment (Rack) Room. Electronic equipment is usually mounted in cabinets or racks, roughly the size of file cabinets. In a large station, they may be grouped for easy maintenance into a single equipment or rack room. In smaller stations, they will be located in the control rooms. In either case, access for servicing is essential. Racks are sometimes used to form the outside wall of one of the control rooms, but this is not suitable for the combo arrangement in which one room serves as both studio and control room.

d. Maintenance Shop. The maintenance shop is an electronics workshop and must be convenient to control and rack rooms. In addition to the usual workbenches and test equip-

ment, space must be available for spare parts and portable equipment for use on "remotes" (off-premises broadcasting). A 10- by 12-ft space is adequate for a small or medium-sized station. Usual occupants: one.

e. Telephone Equipment Room. In addition to the telephone equipment associated with voice communications, switchboard, etc., considerable floor space is required for telephone equipment associated with audio (sound) communications lines, including transmission to the transmitter area and receipt of incoming transmissions such as those from a radio network, etc. Local telephone company representatives should be consulted for requirements early in the planning process.

f. Automation Equipment Room. Automation equipment may be located in a control room or in a separate space. There are no special listening requirements. However, if the equipment includes card punching or tabulating equipment (used to program the automated switchers), the room can be noisy, and acoustical treatment on ceiling and walls is desirable. A glass partition will permit monitoring of the equipment while helping to contain the noise. No standards can be given for room size as this depends entirely on the equipment to be used.

3. Other Broadcasting Facilities The following facilities will not be required in all stations, but where used, they are usually closely associated with the on-air facilities.

a. Newsroom. Similar in appearance and function to the city room of a newspaper, the newsroom is the central point for gathering and editing of news stories prior to broadcast. In some cases, news may be broadcast directly from the newsroom. Special tables permit close contact between correspondents and conserve space. Newsrooms will include television monitors, an assignment board, bulletin board, and mailboxes. In some cases, particularly in large networks, separate offices are required for certain correspondents and

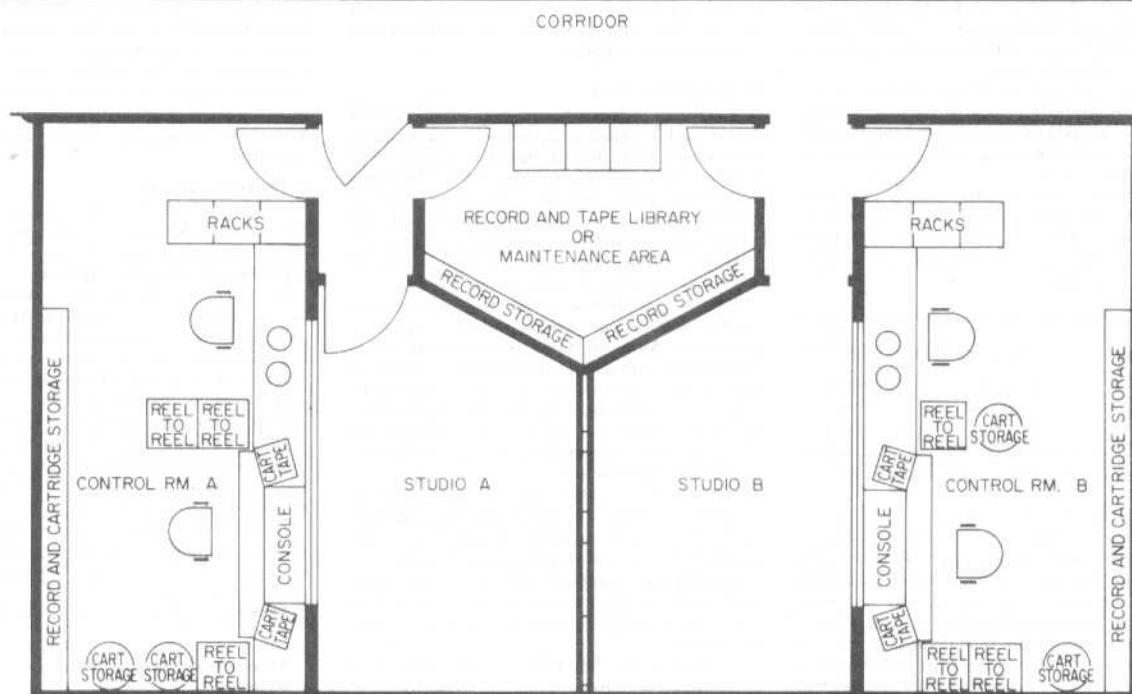

Fig. 3 Two-studio layout for a music-oriented FM station. (Designed by Fenwick S. LaBoiteaux.)

RADIO STATIONS

writers; these should open onto or be not far from the newsroom.

From a construction standpoint, design of the newsroom is similar to a large, very busy office. Even where news is broadcast directly from the newsroom, the background noise is usually not objectionable. (At least one all-news station plays recorded news-printer sound as background to its news broadcasts.) News facilities will vary depending on the extent of news operations at the station.

(1) The most elementary is the "rip-and-read" operation, so-called because the announcer or disk jockey leaves his post only long enough to tear off a sheet from the wire service teleprinter, which he then reads on the air. Here, the only "facility" is a printer in a closet.

(2) A typical music and news station might have a news staff of five, most of whom would be out on assignments. A room about 15 by 25 ft with three desks would suffice.

(3) An all-news station might have a staff of about 14, plus an editor. Desk space for each man is necessary. This type of newsroom is shown in Fig. 4.

b. News Printers. An important feature of the newsroom is the bank of teleprinters representing various wire services, weather, etc. These must be readily available to the newsroom, but since they are noisy, are often enclosed in a separate room acoustically treated to reduce clutter.

If operating personnel insist on locating the printers within the newsroom, consider enclosing them in a sound-proof container with hinged covers. Telex or TWX machines should also be isolated, if possible.

c. Tape and Record Library. Ideally, the tape and record library should be convenient to the studio, especially for music-oriented stations. However, since the studio area may be congested, it may be necessary to locate this elsewhere; the extent to which this can be tolerated is very much a variable and depends on local operating practices. (Fig. 3.)

For a station featuring popular contemporary music, a space 10 by 15 ft should suffice. A station with a very extensive library of classical music may require a much larger area. Normally, the library will be used by only one or two persons at a time.

Standard cabinets used for storing 12-in.-diameter long-playing records can accommodate approximately 60 records per foot of shelf, allowing enough space to permit easy insertion and removal.

Tapes, which are rapidly supplanting records, come in three forms: reels, cartridges and cassettes. Reels are stored in cardboard boxes; cassettes and cartridges do not require a separate container.

Medium	Usual dimensions	Per foot of shelf*
Reels	7 1/2 by 7 1/2 by 1/2 in.	16
Cartridges	5 1/2 by 4 by 1 in.	10
Cassettes	4 by 2 1/2 by 1/2 in.	8

* Allowing space for uprights, vertical dividers, etc.

d. Listening Rooms. As part of the library, or closely adjacent to it, should be facilities for auditing or listening to tape and records. Again, layout is a function of operating practices. If station personnel will use earphones, listening can be done in the library itself; if they insist on loudspeakers, the listening rooms should be separate and isolated acoustically from surrounding spaces, particularly studios. Provision for one or two listening positions is sufficient.

Fig. 4 Newsroom: all-news station.

e. Editing Room. Most program editing is done in the control room. However, some larger stations can effectively utilize an editing room, which is a facility akin to a control room but somewhat less sophisticated acoustically. Editing rooms are usually a part of the studio complex.

4. Support Facilities

a. Offices. Station offices will include facilities for executives, sales, programming, accounting, scheduling, operations, etc. Planning is similar to that for any other office and will not be discussed here, except to note that particular attention must be given to mailroom and telephone switchboard requirements, since activity in these areas may be high compared with a business firm of the same size.

Relation of offices to studios will depend on the size of the station and its method of operation. Some stations operate with sales, accounting, and other administrative functions remote from the studios (even in another building). Programming operations, and other functions related to broadcasting should be convenient to the studios but need not be contiguous with them.

b. Conference. For most stations, good meeting facilities are essential. They will be used for contact with sponsors and public officials as well as staff and should have provision for tape playback and other audiovisual presentations. Some stations make effective use of a conference room designed to double as a studio.

c. Reception. Planning of reception areas depends on whether visitors are limited to persons on official business or will include the general public, schoolchildren, etc. If the lat-

ter, a large lobby is desirable where groups on tour can assemble and be met by a guide. The reception area must control access effectively while still providing a welcome to bona fide visitors. Unless a receptionist or guard is on duty 24 hours a day, after-hours access presents a difficult problem. One solution is card access (similar to the system used in some parking garages) for night operating personnel, plus a night bell for other after-hours visitors. The receptionist may double as switchboard operator.

5. Personnel Facilities

a. Toilets. Plan toilets and rest rooms as for an office. Consider after-hours access. If public tours of the facility are anticipated, size toilet facilities for the visitors.

b. Cafeteria. Need for a cafeteria depends on the size of the station and the availability of other food service facilities. However, even if a complete cafeteria is not to be provided, consideration should be given to a snack bar with vending machines. This is particularly important for after-hours use when other food service facilities are not available or for operating personnel whose duties do not permit them to leave the station. The snack bar can do double duty as a lounge.

c. Parking. Parking needs are a function of local conditions, including the availability of public transportation. Planning is similar to that for offices.

Parking needs may include the following:

- Station employees
- Visitors
- General public
- Station vehicles (see following paragraph)

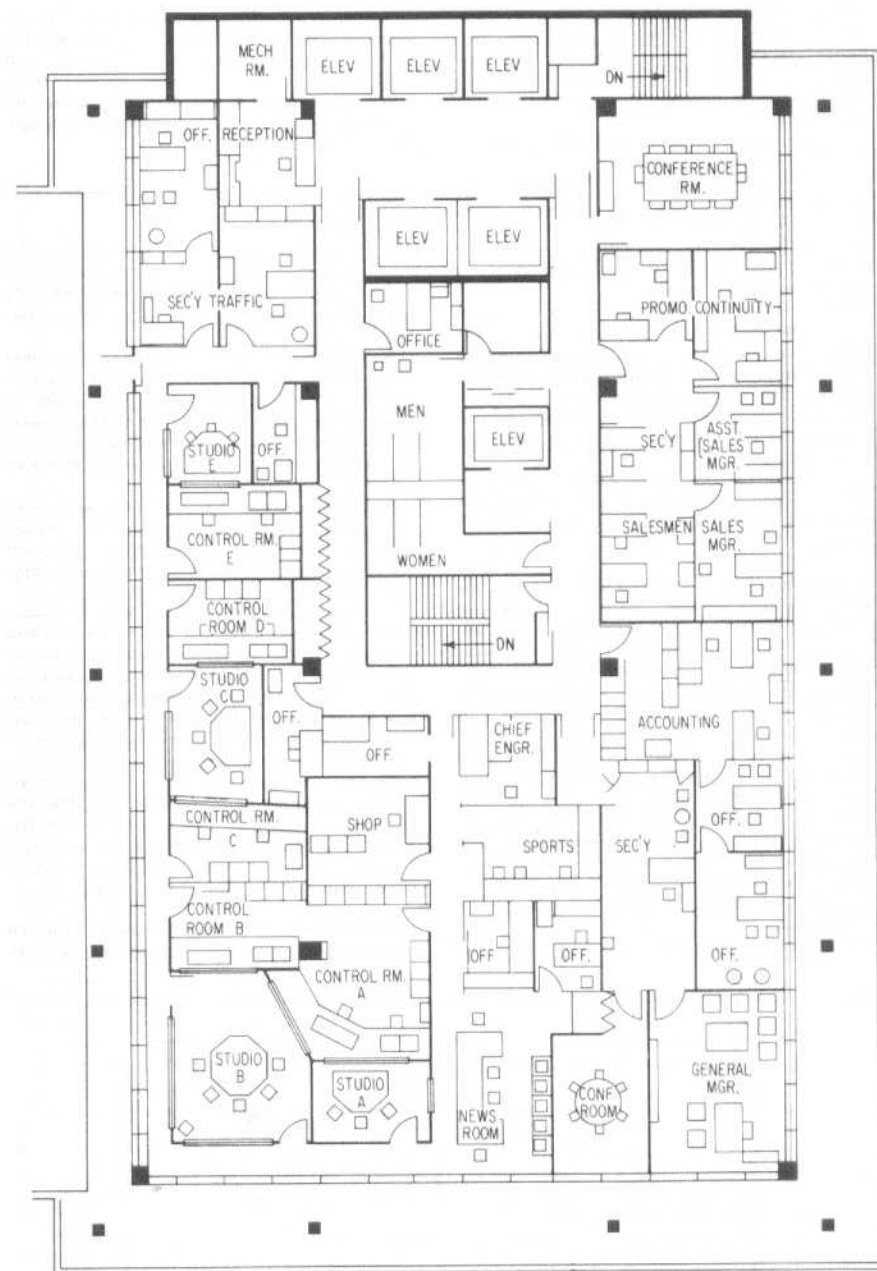

Fig. 5 Floor plan of a station serving a large metropolitan area. Files, storage, and mimeograph are on another floor (not shown).

6. Facilities for "Remote" Operation Availability of lightweight, portable recording equipment has led to an increase in the amount of programming material originated outside the station. It is likely that this type of activity will increase and most stations will have one or more vehicles specially equipped to handle remote (off-station) operations.

Facility needs include garage space for station vehicles and storage space for portable equipment used in remote operations. Storage should be convenient to vehicle parking areas and safe from pilferage. The garage should have ac power, and space should be available for minimum maintenance or troubleshooting of mobile equipment that cannot readily be removed from the vehicle.

E. Layout Planning

1. On-Air Facilities The on-air facilities form the heart of the station and should receive primacy in planning. Since these facilities share common utilities and personnel and require sound isolation from the rest of the building, they are usually grouped together in a tight "island." This makes for operating convenience but is inflexible for changes.

a. Number of Studios. Two studios and two control rooms permit one studio to be used for editing or recording while the other is on-air. Some small stations get by with a single studio, using a second microphone position in the control room. Similarly, automation may obviate the need for the second studio. A larger

station's needs can be determined only by careful study of its operations, including the amount of original programming planned.

b. Layout. Layout of the on-air complex requires understanding of the station's method of operation. Usually, direct visual contact is desired between studio and control room. Flexibility is provided by making it possible for each control room to handle more than one studio. Studio doors should not open directly into adjoining rooms or general corridors; where this is unavoidable, provide a sound lock at the entrance.

Although this is undesirable acoustically, operating personnel may require studio windows to the outside, either to permit the announcer to observe weather conditions or to give passersby a view of operations. A good solution in this case is use of a glassed-in corridor between studio and outer wall. Figure 5 illustrates a station where this system was employed.

c. Sound Isolation. There is an important trade-off between space requirements and complexity of construction. Isolation between adjoining rooms may be accomplished by using dividing partitions or by separating the two rooms involved. While cost is lower, the second scheme requires more floor area. Figure 6 shows a hypothetical layout for the on-air facility using corridors for sound isolation.

d. Allowance for Growth. Expansion of the on-air facility after the station is in operation is both difficult and costly. Accordingly, it is well to anticipate the need for an additional on-air facility. As an example, a room can be built to studio standards but used as a listening room, library, or office until it is required for studio purposes.

e. Three-dimensional Planning. Planning of on-air facilities requires consideration of the third dimension. In studios, maintenance of a minimum inside height of about 9 to 10 ft is important for proper acoustics. At the same time, space of 4 ft above the ceiling is desirable to accommodate ducts and other ceiling utilities.

2. Newsroom The newsroom must be accessible to the studio complex. A news-oriented station may insist on direct visual contact between newsroom and studio for signaling of "hot" news items. One solution is to place the newsroom on the opposite side of a corridor to the studio, with windows in both walls.

3. Circulation Circulation should be around, rather than through, the on-air complex. Visitors can view operations through soundproof windows. Corridors can be used to provide separation between the studio complex and adjoining spaces as well as a sound lock between the technical spaces.

F. Studio Acoustics

Acoustical design of studios, control and editing rooms requires the services of a specialist, particularly for the architect unfamiliar with such work. However, this section will touch on some of the points about which he should be consulted.

1. Objectives of Acoustical Design Basically, there are two objectives in the acoustical design of on-air facilities. The first is to attenuate or exclude unwanted sound from the room, and the second is to provide the desired acoustical characteristics within the room for the sounds reaching the microphone. The latter requirement has been simplified by extensive use of prerecorded music, since acoustical requirements for speech are less critical. Atten-

RADIO STATIONS

uation is still critical, particularly in stations offering contemporary rock music, where listening in adjoining rooms is done at high sound levels.

Each of these objectives will be considered in turn. In either case, the key planning factor is the nature of the broadcasting operations. It is most important that station management participate in setting acoustical design targets.

Acoustical design for control rooms is similar to that for studios. The objective is to have the sound (from loudspeakers or earphones) reaching the control operator's ear match that originated in the studio (or prerecorded) as closely as possible.

2. Room-to-Room Isolation

a. Attenuation. To exclude sounds, each studio and control room is designed as a separate "envelope," independent of the basic building structure. The first step is to establish, for each room, the permitted level of residual noise, usually expressed in noise criteria (NC) levels.¹ Typical NC levels are 20 for studios and 25 for control rooms.

The next step is to identify sources of hostile sound and to establish required room-to-room attenuation factors. Attenuation, expressed in decibels, represents the sound power loss from one space to another and determines the design of partitions, hung ceilings, windows, etc., and the need for independent "floating" floors. It should be established only after the most careful consultation with station management. As an example, if adjacent studios will be used only for news and interviews, the room-to-room attenuation may be about 40 db—using construction similar to a good private office. Where loud music is to be played, required attenuation can reach 60 db or even higher, with significant effect on cost and complexity of construction.

On the other hand, planning should also consider future program changes, since it is very difficult to upgrade a studio without total reconstruction.

b. Floor Isolation. Successful radio studios have been built using a common floor slab. Again, this is very much a function of the sound levels expected within the rooms. Where extreme sound levels are unavoidable, each studio must be placed on its own floating floor supported on springs or neoprene isolators. Note that where used, the floating floor will also support the entire studio envelope: inner walls and ceiling.

c. Doors. Doors are the Achilles' heel of every studio installation. A sound lock is an arrangement of two sound doors separated by a small vestibule. It is analogous to a light lock at the entrance to a photographic darkroom in that it prevents accidental sound leakage into a studio if the door is opened while the studio is in use. "Hostile" sounds, such as those that may become a problem when there are two separate studios, should be separated by at least two doors which should, if possible, not be opposite to each other.

Doors should be sound rated and equipped with gaskets or seals, including drop seals at the threshold. They should have hydraulic closers and handles (instead of latches) and should be provided with small viewing ports.

d. Design Details

(1) Windows must be tightly gasketed. Multiple-pane windows are common; whether

they are actually needed is a function of room-to-room attenuation. For most purposes, two panes are sufficient; but to be effective, the two panes must be in independent frames and must be of different thickness to prevent resonance.

(2) Fluorescent lighting, if used, should have ballasts removed.

(3) Particular attention must be paid to penetrations through the envelope; entries for ductwork, conduit, cable trays, and other services must all be designed and not left to the contractor if they are not to defeat the carefully planned envelope.

(4) Corridors within the on-air complex should be carpeted to minimize foot-impact noise. Consideration should also be given to carpeting areas above the studio complex. Opinion differs on the need for carpeting within the on-air facilities themselves. While absorbing foot noise, it makes movement of equipment difficult.

(5) Studio tabletops should be of cork or felt to minimize paper-shuffling noise, and to prevent unwanted reflections of the "talent's" voice.

3. Room Acoustics Room acoustics requires the proper balance between "hard" (sound-reflecting) and "soft" (sound-absorbing) surfaces, which is a function of the type of sound (speech, music, etc.), the room size, and the type of microphones that will be used. The tendency is towards very "dead" (absorbent) studios and control rooms. (If reverberation is desired, it can be added electronically.) Absorbent wall treatment and closely held microphones reduce the problem of reflection from parallel, hard surfaces that used to require skewing of opposite walls. Highly directional microphones may also prevent unwanted echos or "slap" from hard glass surfaces. Where a naturally "live" (reverberant) studio is required, walls should be skewed.

It is also important that sound absorption be

uniform over the frequency spectrum. This is done by spacing out absorbent material such as fiber glass over a portion of the walls and ceiling.

A traditional rule of thumb for studio acoustical design is that the height, width, and length should be in the ratio of 3:4:5.

G. Utilities and Services

1. Electricity

a. Power Source. For a radio station, the most important utility is a reliable power source. Incoming service should be stable as to both voltage and frequency and free from interruptions.

b. Technical Power. Electronic equipment should be fed from a separate "technical" or "clean" power feeder. No lights or building loads should be placed on this feeder. Where voltage fluctuations are expected, provide voltage regulators for the technical power feeder.

Secondary wiring from a technical power panel within the room to the electronic equipment is usually part of the radio equipment installation, but the architect may have to provide the necessary conduits or raceways.

c. Emergency Power. Even with a reliable power source, outages and "blackouts" are still possible. The most common emergency power source is a diesel engine generator equipped with controls to start automatically when voltage drops to a predetermined level. An automatic transfer switch shifts from normal to emergency power and prevents simultaneous connection to both sources. A brief off-air period can usually be tolerated, so that the cost of no-break power is not warranted. If the station is a member of the government-sponsored Emergency Broadcasting System (EBS), it will require a two-week fuel supply.

2. Air Conditioning Air conditioning is required in the studio's control and equipment rooms to

Fig. 6 Hypothetical layout for a radio studio built around a central core. (Designed by Fenwick S. LaBoiteaux.)

¹Since the apparent loudness of a sound varies with its pitch (frequency), curves relating sound power level to frequency, known as noise criteria (NC) curves have been developed to express the levels of residual noise in a room.

protect sensitive equipment, as well as for comfort, and it is usually provided in other areas in keeping with modern practices.

Special consideration must be given to acoustical requirements to prevent ductwork from carrying unwanted sounds from one room to another and to exclude fan and duct noises. Proper acoustical design of the air-conditioning system starts with equipment selection and its isolation from the building structure. It includes careful duct routing to avoid short circuiting of sound from one area to another with mains located outside the on-air complex. It also includes proper use of sound traps, turning vanes, flexible connections, and duct insulation to remove residual duct noises. Finally, careful attention to wall penetration is essential.

Air distribution inside these areas must be at low enough velocity to keep air and duct noises within the noise criteria (NC) levels selected for the space. As a rule of thumb, air velocities in branch ducts should not exceed 400 fpm at the point where the duct enters the studio. Velocity out of the diffusing element should not exceed 300 fpm, and 200 fpm is preferred. In addition to maintaining this low velocity, diffusers must also be of a type that will not in themselves generate noise.

3. Communications

a. Audio Signal Feeds. Except where studios and transmitter facilities share a single facility, broadcasting signals are transmitted from the studios to the transmitter by microwave, leased telephone lines, or a combination. Where microwave is to be used, a study must be made of terrain profile, since microwave requires a direct line of sight. Intermediate stations are used to surmount obstacles.

Central network programming may also be received by either microwave or leased telephone lines.

b. Telephone, Telex, and Wire Printers. Telephone services are important, particularly for a news-oriented station. Most stations will probably require one or more wire service teleprinters. Consideration should also be given to the need for telex and facsimile installations.

c. Point-to-Point Radio. A news-oriented station will have a significant requirement for local radio communications facilities. These are facilities for point-to-point wireless communications between the station and its reporters in field locations and are similar to police and fire radio. Usually transmission requirements can be satisfied by roof-mounted antennas. Roof antennas are also required for radio and television pickup.

4. Audio Wiring Audio wiring is the low-voltage cabling, similar to telephone wiring, used to interconnect the electronic equipment and transmit the broadcasting signals within the studio. It is quite extensive and must be considered in design. Audio wiring may be distributed by one or more of the following:

- Floor trenches with removable covers
- Underfloor duct, conduit, or raceway
- Hollow, elevated floors similar to those used in computer rooms
- Overhead cable trays or raceways
- Horizontal baseboard raceways

Floor channels and underfloor duct do not lend themselves to future changes in equipment layout. Cable trays or "ladders" are the most flexible from the maintenance standpoint, since cables are easily removed and inserted but are acceptable only if permitted by local codes. Cable system routing must be carefully checked for the interference with ducts and

lights (if in the ceiling) and to avoid compromising the acoustical "envelope" surrounding each studio and control room.

5. Other Following is a brief checklist of some of the other systems that may be required:

- a. *Compressed-air and Central Vacuum Systems.* Large stations and networks may require central systems serving control rooms, rack rooms, and maintenance shops. They are used for cleaning and general maintenance.
- b. *Loudspeaker System.*
- c. *TV Monitor System.*
- d. *Clock System.*

II. RADIO TRANSMITTER FACILITIES

A. Description

Radio transmitters may be attended or unattended. In some smaller stations, transmitter and studios share a single building; but for AM facilities, this usually means a less than optimum location for one or the other. The following discussion assumes that studio and transmitter facilities are separate.

Besides the transmitter building, the main feature of a transmitter installation is the broadcasting antenna. For AM stations, the antenna is usually one or more radiating towers. For FM, the tower serves as a support on which a separate radiating antenna is mounted.

1. AM Transmitters For an AM transmitter, the main structures will include the towers and their foundations, the guy anchorages (usually three, spaced radially at 120° about each tower base), and the transmitter building, which will be discussed subsequently. There is also a small building, of concrete or block, at the base of the tower, known as the "tuning house" or "coupling house," which houses equipment for matching the transmitter and its transmission line to the impedance of the antenna.

An important but less obvious feature of AM installations is the ground system. A copper-mesh screen, about 40 by 40 ft, is centered at the base of the tower. Buried copper cables extend outward radially from the mesh every three degrees. These are generally 6 to 12 in. below ground surface.

If the antenna is "directional," i.e., designed to broadcast in a particular, nonuniform pattern, multiple antennas (an "array") must be used instead of a single tower. Tower height is a function of the station's assigned wavelength, with most AM towers between one-quarter and five-eighths of a wavelength in height. As an example, a station with a frequency of 600 kilohertz (kHz) (1 kHz = 1,000 cycles per second) has a wavelength of 1,640 ft and could have a tower height of between 400 and 1,050 ft.

Because of the cost and land area required for an AM transmitter, some competing stations have joined forces to operate from a single tower. This arrangement calls for highly specialized design of the tower, and services of a professional radio engineer become essential.

2. FM Transmitters FM facilities are limited to the antenna, which is usually mounted on a tower or mast, plus the transmitter itself. It is common for several FM stations to share a single mast or tower as well as for FM antennas to be mounted on a TV or AM antenna tower.

The main requirement for an FM antenna is height to clear the surrounding terrain. FCC

regulations control the relationship between height and allowable broadcasting power, which depends on the class of station. Most FM antennas are between 200 and 1,000 ft high.

B. Site Selection

1. Location Transmitter location is determined by antenna requirements, which differ sharply for AM and FM. For AM transmitters, a rural location is usually necessary to achieve the required ground conductivity and avoid interference with reception in nearby homes, as well as to find the space needed for the ground system. FM antennas, on the other hand, require mainly height and have been successfully located in cities, on top of tall buildings.

2. Area Required For an AM station, the site must be large enough to contain the antenna array plus the guys and ground radials. Tower guys require a radius of about two-thirds the tower height, while the ground radials should be about half the length of the station's wavelength. In the example given above of a station with a frequency of 600 kHz, the ground radials for a single tower should be about 820 ft long.

For an FM station, the site need only be large enough to contain the tower base (or the guys, in the case of a guyed tower) plus a small transmitter room. Thus, a tall building that can support the required mast makes a good FM transmitter site. A TV tower that can carry an additional antenna is also a good location.

3. Technical Considerations Site selection for a transmitter facility is highly technical and is best entrusted to a consulting engineer specializing in this kind of work unless the station itself possesses the necessary expertise. In addition to studies of ground conductivity (for AM), careful analysis must be made of potential interference with other stations, all in accordance with detailed FCC regulations. Air traffic patterns must also be considered, as must local zoning regulations.

4. Other Considerations In addition to the necessary technical considerations, the site should have:

- All-weather access
- Reliable power supply
- Reliable telephone service
- Parking space

It should lend itself to proper security. It should be possible to provide water and sanitary sewage either from public utilities or on-site facilities.

C. Site Planning

The ground area required by the spread of the guys and the need to accommodate the ground radial system can be quite extensive. Some of this acreage can be sold or leased out provided provision is made in the lease or deed for protection and maintenance of the ground system. Similarly, the area between the tower base and the guy anchorages, which is largely unused, can be devoted to grazing or other uses that will not disturb the ground system.

Safety should be considered in locating the transmitter building. Although structural tower failures are rare, collapses caused by accident (aircraft) or sabotage are not unknown. If possible, the transmitter building should be so placed that, in the event of such a catastrophe, the tower would be likely to fall clear of the building. An AM transmitter may be located some distances from the antenna.

Commercial RADIO STATIONS

Fig. 7 Small AM or FM transmitter building.

FM transmitters must be as close to the tower as possible, to minimize line losses.

Concern over continuity of broadcasting has led some stations to provide an auxiliary antenna. This is costly both in terms of construction and land area. Perhaps a better solution is an agreement with other stations permitting some kind of dual use of their facilities in the event of an emergency.

D. Construction

1. General

a. Grounding For an AM facility, all structures within the transmitter area, including the transmitter building, must be properly grounded and tied into the ground radial system. In concrete buildings, reinforcing steel must be made electrically continuous and bonded to the ground radial system.

b. Soil Conditions AM antennas have been located in marshy or waterfront land, to take advantage of good soil conductivity. This may require pile foundations for towers and buildings. In swampy areas, consideration must be given to possible land subsidence which could affect the grounding system.

2. Towers A ground-supported tower is usually designed as a slender mast, pinned at the

base and braced by one or more levels of guys. Fixed-base or cantilevered towers (without guys) are now used only for masts on the roofs of buildings. The tapered shape of a self-supporting tower is also undesirable for an AM transmitter where, as previously indicated, the tower itself is the radiating element. Electronic considerations will determine the height and general arrangement of the tower.

AM towers, which are usually of steel, are given a heavy coating of zinc galvanizing. This serves to protect the tower, but its primary purpose is to provide electrical conductivity. At radio frequencies, the "current" flows mainly along the outside periphery of the tower. Sections of the tower must be electrically bonded together for the tower to function properly.

FM towers serve only to support the separate antennas and are designed purely for structural considerations. All towers require aviation marking (alternate white and orange striping) and obstruction lighting; details are found in FCC regulations.

3. Transmitter Building In addition to space for the transmitter itself, there should be space for the associated equipment racks, maintenance, spare parts storage, and toilet facilities. Even an "unattended" facility is occupied peri-

odically for inspection and maintenance. If the station is quite remote, minimal kitchen facilities and a shower may be desirable.

The amount of equipment which must be contained in the transmitter building depends on the station's assigned operating power. This can vary from 250 watts for very small stations to 50 kilowatts for the larger commercial stations. For the larger stations, equipment may be quite heavy, so that floor loads must be checked, particularly when locating the transmitter in an existing building.

In cold climates a carport may be desirable to protect the operator and his vehicle against ice falling from the tower. This can be a more serious hazard than it may at first seem.

When two or more stations share a single antenna system, the need for separate transmitter buildings or rooms will be determined by local operating preferences; both systems work well. Figure 7 shows the layout for an unattended transmitter in a rural location.

4. Utilities

a. Communications. Program signals may be brought to the transmitter by leased telephone lines, microwave, or a combination. Microwave requires a series of direct lines of sight.

b. Power Some transmitters have two primary power services from different substations and feeders for greater reliability; usually automatic switching between services is included.

Emergency power is required for Emergency Broadcasting System (EBS) stations and may be desirable for others, particularly where the primary power source is subject to interruptions. If provided, it should be sized to handle minimal lighting, tower obstruction lighting, and transmitter ventilation as well as the transmitter itself.

c. Heating, Ventilating, Air Conditioning. The transmitter generates considerable heat, which must be removed by mechanical ventilation. This system consists of a filtered intake with a ducted exhaust connected directly to the transmitter. Dampers are arranged so as to reduce the amount of outside air during the winter and make use of the transmitter heat. Supplemental heat is usually required to maintain comfortable working conditions in winter.

Air conditioning is not required unless the transmitter plant will be occupied for a large part of each day.

d. Lighting. Good lighting (office levels) should be provided to facilitate housekeeping and maintenance.

e. Site Development. Since an AM tower is dangerous when in operation, its base must be fenced, as should each of the guy anchor blocks, to discourage tampering with the guys. Fencing of the entire area and security lighting may also be desirable. Planting or other erosion protection for the ground around the tower should be provided.

By JOSEPH HOROWITZ, P.E., Manager, Planning & Design, Facilities Engineering Department, Columbia Broadcasting System, Inc.

TELEVISION BROADCASTING FACILITIES

A. Scope

Television broadcasting facilities range from a tiny station serving a small community to a major network facility with multiple studios and extensive supporting facilities providing programming to hundreds of city and regional markets. Because of the wide variation in requirements, this article will be limited to basic planning considerations plus a brief description of each of the facilities that may be required. Emphasis is on program origination facilities; transmitter installations are covered only briefly.

B. Classification

Television facilities may be classified as to purpose, type of programming, and extent of audience involvement. These factors, plus the size and budget of the station, determine the facilities to be provided and their relationships.

1. Purpose

a. Local Station. A local television station serves a defined geographical area as authorized by FCC licensing. Programming will reflect the size of the market (area served) which may range from a small town to a large metropolitan area. Many local commercial stations are affiliated with one of the major networks, which provides a large portion of their programming. Another common source of outside programming is syndicated tape and film.

b. Network. Program origination facilities for a television network differ from those of a local station in that they are usually larger, with a greater variety of supporting services. They originate program material for use by affiliated local stations.

c. Cable Television (CATV). Facilities for cable television consist of a receiving antenna and a small head end building containing the associated electronic equipment. Incoming programs are distributed over a network of cables to subscribers. Some CATV operators have austere studios suitable for local news and interviews.

d. Other. Schools and industrial concerns are making increased use of television for educational and training purposes and have set up studio facilities for this purpose. Programs may be broadcast or distributed over closed circuits. In addition, a number of cassette-type media are now available on which programs may be recorded for later playback on closed circuit.

2. Type of Programming A basic planning factor is the extent of locally originated programming material as opposed to network-supplied or syndicated material. Locally originated programs require a studio; studio type and extent of supporting facilities will depend on nature of programming planned.

a. News studio requirements are usually quite simple. Supporting facilities will include news gathering services, plus storage and editing facilities for film and videotape. Coverage

of local news events will require remote equipment.

b. Interview and panel discussions can be handled with the simplest of studios and minimal support facilities.

c. Dramatic programs (such as soap operas) call for elaborate facilities, extensive sets, props, makeup, wardrobe, and other support facilities. Studio lighting is also more elaborate.

d. Musical and variety programs are the most demanding. Studios must accommodate anything from a single performer to a large group and require great flexibility in lighting, scenery, properties, etc. Supporting facilities are similar to those for dramatic programs, but usually there is less opportunity for reuse of materials in subsequent programs.

e. "Remotes," or broadcasts originated outside the station's studios, include coverage of sports events, political conventions, news, and other public events. Facilities required for this type of operation (in addition to control room and other technical facilities required for on-premises programming) are described below.

3. Audience and Public Involvement Studios may be further classified as audience or nonaudience. An audience studio is a cross between a theater and a studio, with the usual theater considerations of sight lines, audience acoustics, and public safety complicated by the requirements for camera operation and lighting.

The public may be involved in television facilities in ways other than as studio audiences. A station planning to encourage visitors to view the behind-the-scenes operations should make ample provision for such circulation.

Another case is the special-purpose facility which has as a major function, the training of television technicians and operating personnel. Here, control rooms and other supporting facilities must be planned to do double duty as classrooms.

C. Other Planning Factors

In addition to the classifications described, the following factors must also be considered:

1. Hours of operation.
2. Union regulations affecting technicians, stagehands, etc.
3. Management decisions on contracting out vs. work done in-house. Examples are rental of scenery props and costumes and outside film developing and storage.

D. Site Selection

Site selection has much in common with radio studios, but it will also depend on the planning factors previously enumerated. The site for an audience studio is planned much as is that for a theater, with considerations of parking, transportation, and audience egress.

All studios require truck loading facilities for delivery and removal of heavy cameras and electronic equipment and—if dramatic or variety programming is planned—scenery and

properties. Insofar as possible, avoid a site subjected to vibration, such as that caused by a highway.

E. Facilities

The listing which follows includes spaces required in a larger station, a network or a college facility where exposure to all facets of television broadcasting is desired. Smaller stations will require fewer and less elaborate facilities.

1. Studios A television studio is any room where television cameras are used. Studios range in size from that of a regular office (with the camera shooting in through a window or open door) to large studios of 100 by 100 ft used for dramatic or variety programming. Because of its importance, a brief discussion of studio planning is contained in Section G. (See Fig. 1.)

2. Control Rooms Control rooms contain electronic equipment for monitoring and controlling the studio output. They may have separate compartments for sound (audio), picture (video), and lighting control. An announcer's booth incorporated with the control room must be acoustically isolated, since it contains a live microphone.

Control rooms must usually be accessible to the studio which they serve; direct visual contact may or may not be necessary, depending on operating practices (Fig. 2).

Acoustical considerations are similar to those for radio control rooms. Lighting should be adjustable to permit observation of television monitors.

3. Technical Facilities Technical facilities house the extensive electronic equipment which supports broadcasting operations. Because of the space required and the fact that some of this equipment is noisy, only the smallest stations locate it in the control rooms.

To facilitate maintenance, the technical facilities are often grouped together in a Central Technical Area (CTA). CTA need not be adjacent to the studios, provided good communications are available. A dust-free temperature-controlled environment is essential. Following are the facilities that make up CTA:

a. Equipment (Rack) Rooms. The equipment room houses ancillary electronic equipment that does not require attendance or adjustment during programming, such as audio and video equipment, switching devices, transmission equipment, etc. A separate room facilitates maintenance and simplifies design of the control room. The rack room need not be adjacent to the control room(s) but should be convenient to the maintenance shop.

b. Videotape Recording (VTR). The usual medium for television recording is magnetic tape using a device called a videotape recorder (VTR), which resembles a very elaborate magnetic sound tape recorder. The VTR area for a local station may contain from two to six machines. Central network facilities will have more.

Commercial TV STATIONS

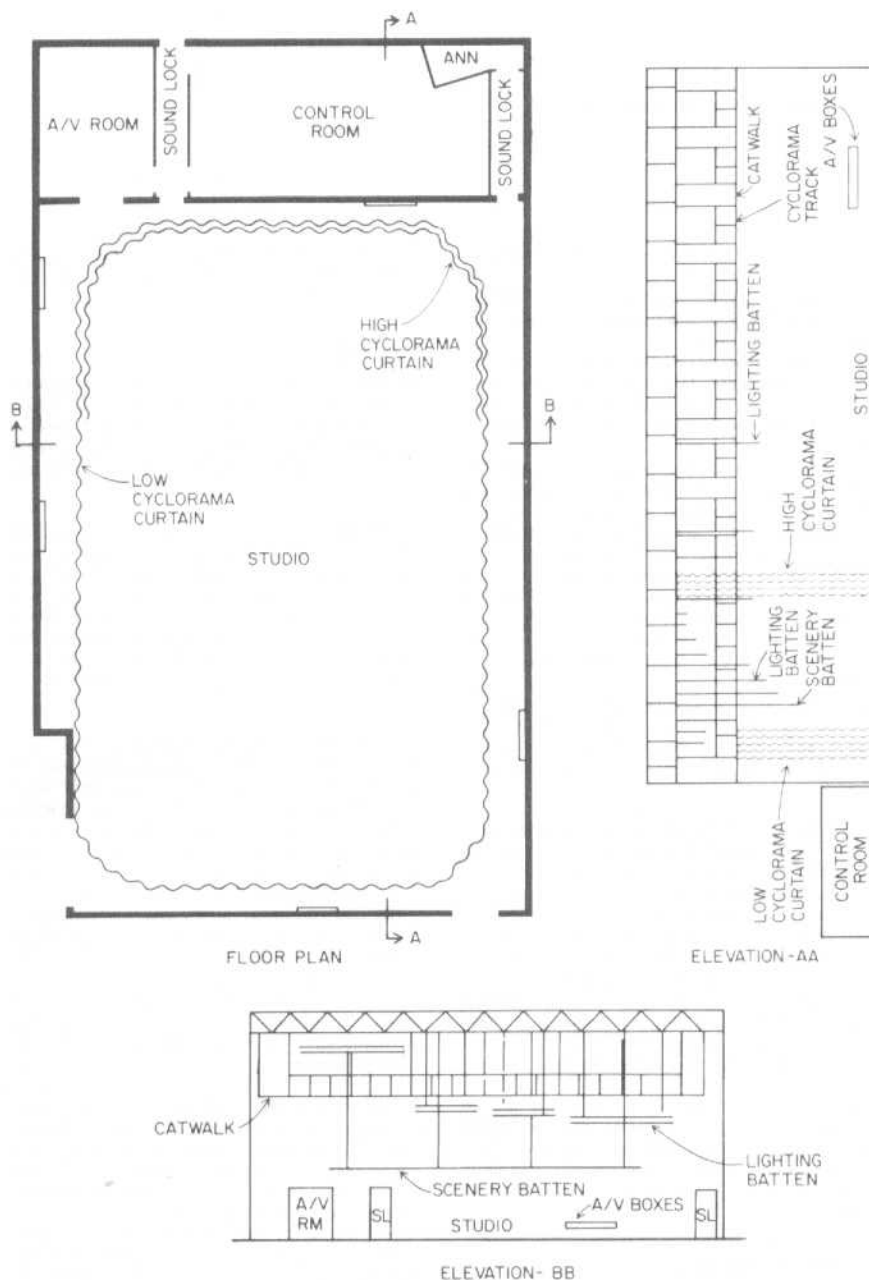

Fig. 1 Typical studio layout.

c. Telecine. Despite the advantages of magnetic tape, much television programming will continue to originate as motion picture film. In addition to the popularity of full-length feature film as television fare, off-station news and special events are usually easier to record with portable motion picture cameras. As the name implies (*tele*-television, *cine*-cinema), telecine contains assemblies that combine motion picture and slide projectors with a television camera. Size will depend on the number of machines to be housed.

d. Master Control. Larger stations with several studios may require a central or master control for final switching and monitoring of the on-air operation.

e. Maintenance Shop. This is an electronics workshop with considerable space for spare parts. It must be as convenient as

possible to the central technical area. Ideally, it should also be convenient to the control rooms, but this is not always possible.

f. Telephone Equipment Room. For large stations and network facilities, telephone equipment associated with transmission of television programming requires a substantial floor area which is usually close to or a part of the central technical area. (This equipment is distinct from that used for normal telephone communications.)

g. Film Recording. This area contains equipment for recording, on motion picture film, material originated electronically. Before the advent of magnetic tape, this was the only method for recording television programs. Some network installations and very large stations may still require a film recording facility which can be adjacent to or part of tele-

cine. Useful adjuncts to film recording are a darkroom and viewing room.

h. Video Cartridges. New methods available for recording television programming in cartridge or cassette form include film (Electronic Video Recording), magnetic tape, plastic tape, and plastic disks. While most are not yet of broadcast quality, they may in time supplement videotape and film as program sources, much as tape cartridges now supplement phonograph records in commercial radio studios. Possible facilities' needs cannot yet be predicted.

i. Program Control. This is a room resembling a control room without a studio where television signals from various sources—such as telecine, VTR, or live remotes—are combined electronically to produce a complete program. It is useful where studios are heavily used and much off-premises work is anticipated. A program control room is required only for the largest stations or network facilities.

4. News Even the smallest station will have local news. The following facilities would be required for a large station or a central network facility:

a. Newsroom. This is similar to a newspaper "city room" with desk and telephone space for newsmen. It usually contains or is adjacent to wire service printers and is usually equipped with TV monitors.

b. Library and Archives. Just as a major newspaper will maintain a file of clippings, a large news operation will have a library of film and tape as well as reference books and other resources. This should be accessible to the newsroom.

c. Special News Studios. Since the live "action" in a news broadcast is usually limited to a man at a desk, larger stations may want a small studio opening directly off the newsroom from which news programs may originate without tying up one of the regular studios. When not in use as a studio, it serves as an office.

d. Graphic Arts. This is a facility for rapid production of charts, photos, and other visual materials. It is used extensively for news as well as other programming. It may vary from a single artist's desk in a small operation to a large room with many artists and facilities, such as a Statmaster, for photo developing and printing.

5. Studio Support Facilities The following rooms are basically similar to corresponding spaces in legitimate theaters and will not be discussed in detail. Need for them depends on the type of programming.

a. Rehearsal halls (these are best kept away from the studio to minimize sound problems).

b. Wardrobe rooms.

c. Dressing rooms (individual and group).

d. Makeup rooms.

e. "Talent" lounge for performers (convenient to studios and dressing rooms). This is often called a "green room" after a similar green-painted room in a well-known concert hall.

f. Multipurpose rooms. These are rooms about the size of a chorus dressing room which can be used, as the occasion demands, for dressing rooms, rehearsal of small groups, lounge, music origination, etc.

g. Ready storage for scenery and props. This must be available as close as possible to the studios to minimize handling.

"Talent" refers to the actors, announcers, and other performers who appear or are heard in programs.

Fig. 2 Studio control room. Note that the control room shown has no visual contact with the studio; wall space is used for television monitors.

h. Crew's lounge. This should also be convenient to the studio area.

i. Storage for cameras, microphones, and lighting equipment. This should be convenient to studios, and if possible, to the maintenance shop.

6. Scenery Facilities for a large station or network will include scenic design (art studio with possibly blueprinting or photostating services), production (carpenter shop, paint shop, stage electrical shop), scenery and property (prop) storage, and facilities for disposal of unwanted scenery.

Facilities to be provided depend on business decisions as well as station size and programming, since many of these functions can be contracted out. Some networks maintain a central scenery fabricating department from which materials are trucked to and from off-premises studios. Whether made on premises or off, scenery and props constitute a significant materials handling problem. The general flow is shown graphically in Fig. 5.

7. Film Facilities for processing (developing), editing (cutting), and storage of film are identical to those in commercial film laboratories and in many cases these functions (except possibly editing) are performed for the station by a commercial film laboratory.

Film storage and handling facilities are usually strictly regulated. In the absence of local codes, refer to National Fire Protection Association pamphlets.

8. Sound Effects Central sound effects rooms—similar to small radio control rooms—are required only in the larger facilities. They need not be adjacent to the studios provided good intercommunications are available.

9. Music Origination Rooms These provide musical background to a studio program. If the instrument (piano, organ, etc.) does not appear visually, it may be located in a separate room to avoid cluttering up the studio. Usually, very close microphone techniques are used, so that acoustical requirements are not severe.

10. Viewing (Screening) Rooms A viewing room may be anything from a room with a 16 mm projector on a table for previewing films to an elaborate miniature theater for showing programs to prospective sponsors. The latter type

should be easily reached from sales and executive areas and convenient to rest rooms and offices. They are not usually related to the studio or technical facilities. Viewing rooms should have facilities for 16 mm and 35 mm motion picture film (if possible, with a separate projection booth) as well as television monitoring.

It is often possible to arrange viewing rooms so that two rooms share a single projection booth. Local code requirements will influence planning and design. The viewing room may also be designed to double as a conference room.

11. Facilities for Outside (Remote) Program Origination By contrast with radio, facilities for remote (off-premises) television broadcasting are quite elaborate. A station planning such activities will require the following:

a. Garage or parking space for the mobile vans containing remote equipment. Since these may be taller than ordinary vehicles, a careful check of overhead clearances is required.

b. A field shop for maintenance of the equipment and for storage of gear. This must be con-

venient to the garage area, since some of the equipment cannot be readily removed from the vans for servicing.

c. For a station with much off-premises work, an extra control room (without a studio) is useful. This permits putting together a remote without tying up one of the regular studios. (See 3i, Program Control.)

12. Echo Chambers Echo or reverberation effects are obtained in one of two ways: using "natural" echo chambers (highly reverberant rooms) or by means of artificial reverberation devices. The natural (physical) echo chambers require isolation from surrounding noise, otherwise they can be located anywhere. Need for reverberation sources depends on the type of programming contemplated.

13. Offices With the exception of those directly related to production, offices may be remote from the studios (even in another building), but they should be convenient to viewing rooms. Executive offices and conference rooms will require closed-circuit television feeds. For major network facilities, consider offices for outside "show units" (producer, director, and their assistants) as well as other employees.

14. Personnel Facilities The larger activities may require cafeteria, first aid, and other support facilities customary in an industrial building. In planning circulation and toilet facilities, consider visitors, schoolchildren, and studio audiences.

15. Building Maintenance Because of the heavy investment in facilities and equipment, television facilities are usually intensely used. Similarly, continuity of air conditioning, electric power, and other building services is essential. These factors dictate allocation of adequate space to building maintenance such as cleaning, repair shops, and spare parts storage.

Utility areas, such as transformer vaults and mechanical equipment rooms, should be liberally sized both to facilitate maintenance and to accommodate future alterations without interrupting broadcasting operations.

16. Site Development

a. Parking needs must consider:

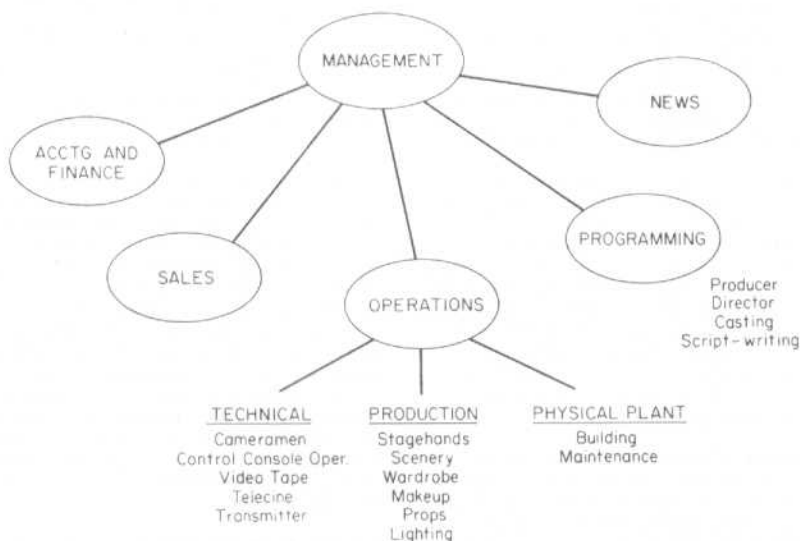

Fig. 3 Television station—schematic organization.

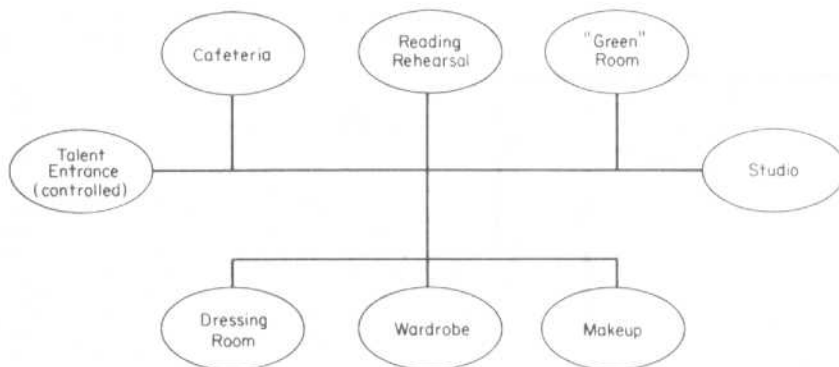

Fig. 4 Performer ("talent") flow.

Station employees
Visitors on business, such as customers, performers, and tradesmen
Studio audiences
General public (guided tours, school-children, etc.)
Station vehicles

b. Off-street loading facilities are essential for scenery and properties as well as heavy cameras, dollies, and electronic equipment. Access is required from the loading facilities to shops, storage area, and studios.

c. Some stations make special use of their outside facilities for programs such as farm or animal shows.

F. Planning Considerations

1. **Circulation** Organization of a typical television station is shown schematically in Fig. 3. A television broadcasting facility includes quite divergent functions. Flows of people and materials that may be in conflict must be separated as in a manufacturing plant. Some of these flows are described below:

a. Office personnel require access to production or technical spaces only rarely. Executive and sales personnel require ready access to conference and viewing rooms.

b. Visitors should be controlled. Sponsors and other official guests should have ready access to offices and screening rooms without going through production or technical areas.

c. "Talent" (performing artists of all types) require access to studios and studio support facilities (see Fig. 4).

d. Technicians and production personnel require access to their areas and to studios.

e. Talent, technical, and production personnel should not have to pass through office areas.

f. Studio audiences, where used, should have access only to studio and toilets. Visits to production or technical spaces should be carefully controlled, as on guided tours.

g. Scenery and props involve significant materials-handling operations. Figure 5 shows the major flows which should be separated, insofar as possible, from the "people" flow.

h. "Show unit" offices (producer, director, and their staffs) are preferably located within easy access to studio facilities, although this is not always possible.

2. **Expansion** Studios and technical rooms are very difficult and costly to expand unless expansion is contemplated in the original construction. One approach is to build the basic shell large enough to accommodate all anticipated requirements. Interior finishes are de-

ferred and the space to be used for studios in the future is, for example, used initially for scenery storage. Where the site permits, a second approach is to locate studios next to an outside wall.

Videotape and other technical areas which do not require the ceiling heights characteristic of studios can be expanded provided the space alongside can be made available. Expansion needs should also be considered when planning fan rooms, duct routing, and other utilities spaces.

G. Studio Planning

The studio is the heart of original programmed television.

1. **Audience Studio** Audience studios present a particular challenge, since camera operation conflicts with the theater requirements for unobstructed sight lines. The resulting studio is usually a compromise. For a production facility with only occasional audience use, removable bleacher seating may be considered.

Television studios require a substantial camera maneuvering space between the production area and the audience seating. Camera runways project out into the seating area to permit long camera shots. Seating area is usually sloped for better audience viewing. Note that it must be possible to aim cameras at the audience as well as at the stage. Musicians are located at the same level as the rest of the production area and are usually enclosed for acoustical reasons.

Audience studios are "places of public assembly" in building code terms, with seat spacing, egress, and other aspects of audience safety and comfort to be considered.

2. **Dimensions** Studios can range from 20 by 25 ft for a very small station to 100 by 100 ft or more for a large facility suitable for all types of programming. Studios limited to news or similar static programming with little movement can be even smaller. A 40- by 60-ft studio is a good size for an average station.

Minimum clearance under the lighting support structure or air-conditioning ducts can range from 10 ft in the news-interview studio to 15 or 20 ft in the larger studios suitable for dramatic and variety programming. Where a walk-on grid is used for lighting, an additional 7 ft or so should be provided between bottom of grid and underside of trusses or beams forming the roof.

3. **Sound and Vibration Isolation** Interior acoustical requirements depend on the type of pro-

gramming. In addition to isolating the studio from outside noise, vibration that could be felt by sensitive cameras must be avoided. This may be caused by outside traffic, building equipment, or an adjoining studio. In extreme cases, the entire studio is "floated" on springs to separate it from the building structure.

4. **Materials Handling** Scenery, props, and other materials used in the studio may be both bulky and heavy. Entrance for large scenery flats is essential, as well as facilities for delivery of heavy items such as an automobile.

5. **Floor Loading** Floor loadings should accommodate the type of programming anticipated, as well as the weights of the cameras which, with their moving carriages (dollies) can be quite heavy. A live load of at least 100 psf is recommended for maximum flexibility in large studios, and some authorities recommend 125 to 150 psf. (The classic example of extreme point loading is an elephant standing on one foot.) Finished floors require greater than usual freedom from irregularities and waves which would affect a rolling camera.

6. **Cyclorama** The production area of the studio is usually surrounded by a cyclorama, a thin, opaque curtain which provides a backdrop to scenery and conceals the walls or any storage outside the production area.

7. **Lighting** For smaller studios, lighting is provided by a combination of overhead and floor-mounted luminaires. Greater flexibility is obtained with an electrified raceway of the Litespan type.

For the larger studios, some type of lighting grid from which light fixtures may be hung is usually necessary. This may be serviced by ladders from the floor, but in the major studios a catwalk system is provided which permits placement and adjustment of the luminaires entirely from above. Individual light pipes or battens that can be raised and lowered are also used (see Fig. 1) permitting adjustment of lights from the studio floor.

Associated with the lighting system is a patch panel, an oversized version of a telephone switchboard, used for making lighting connections. Dimming equipment may be in the studio or centralized elsewhere and remotely controlled by a lighting console in the control room or studio.

H. Space Planning for Utilities

Color television requires very intense lighting—50 to 75 watts per square foot of production area is not uncommon. Heat generated by this lighting must be removed by air conditioning. Location of air-conditioning equipment and duct routing must be considered in original planning. Space must also be allocated to the very extensive wiring which interconnects studio, control room, and central technical area, using under-floor ducts, overhead cable trays, or other means. In one large installation, the ceiling of the central technical area was used as a kind of huge cable tray, with bundled cables laid directly on the grating that served as the ceiling. (The ceiling also served as a plenum for air conditioning.)

Power for electronic equipment ("technical" power) should be separated from that serving building equipment and may require voltage regulation. For a major station, emergency

² The weight here may range up to 5 to 7 tons.

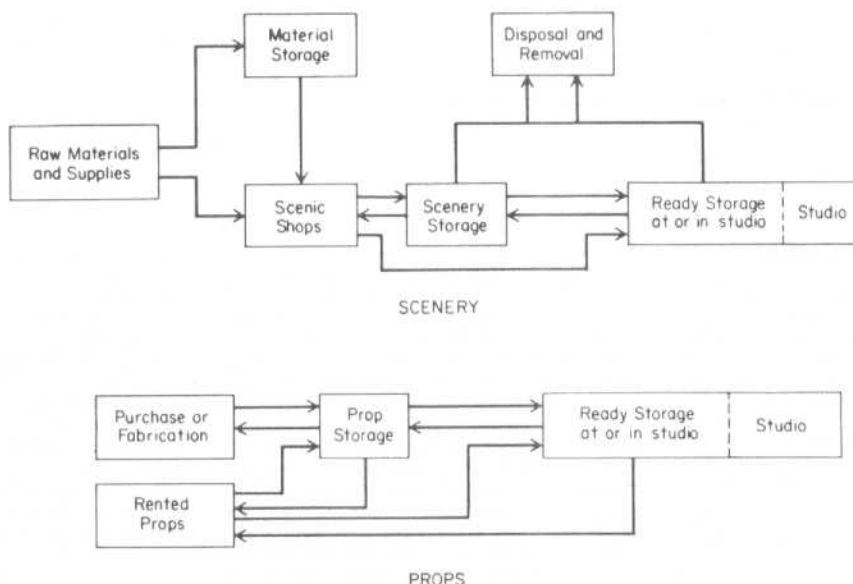

Fig. 5 Materials flow, scenery and props storage.

generators should be considered to provide for continuity of minimal broadcasting, such as news, network feeds, or film. (Emergency studio operation is not usually practical because of the heavy power and air-conditioning requirements.)

I. Transmitter Facilities¹

Transmitter facilities consist of the broadcasting antenna and the transmitter building or room. As with FM, the radiating element (antenna) is mounted on a separate tower or mast, whose function is purely structural.

¹See discussion of radio transmitters immediately preceding this article.

There is no ground radial system as with AM radio transmitters except for lightning protection. Several antennas may be mounted on a single mast or tower.

TV transmission is primarily a line-of-sight phenomenon and is affected by buildings, mountains, etc. For this reason, antenna height is a major consideration, and many television towers are more than 1,000 ft tall.

Because of these heights, particular consideration must be given to falling ice and drifting paint spray when the tower is repainted. In general, physical site planning has much in common with radio transmitter planning.

Planning for the transmitter room also resembles that for radio transmitters, but the equipment and plant facilities are larger and

more complex. Detailed requirements depend very much on the transmitter equipment to be used, and particular attention must be paid to transmitter cooling. (UHF equipment usually requires water cooling.)

In the past, most television transmitters have been fully manned, requiring kitchen and toilet (and even sleeping facilities in some cases). While unattended transmitters are now permitted, the transmitter building will still be occupied for a part of each day, requiring some personnel support facilities. On the other hand, provision should be made for remote monitoring of building services—temperature, fire detection, electric power, etc.—for use during those periods when the station is unmanned. Where continuity of broadcasting is essential, emergency power should be provided.

By MORRIS LAPIDUS and ALAN LAPIDUS, Morris Lapidus Associates

BASIC THEORIES OF HOTEL PLANNING

Before an architectural office begins planning and designing a hotel, it should know exactly how a hotel operates. Every type of building must function smoothly to achieve the end result that the client is seeking. The primary function of a hotel has not changed from the earliest recorded hostelry to the present-day hotel, whether that be a hotel of 100 rooms or 3,000 rooms, whether it be an in-city hotel or a resort hotel, whether it be a convention hotel or a family-type hotel. The earliest hostelry offered "bed and board" as well as pleasant surroundings in which to enjoy both commodities. The earliest hostelries and caravansaries worked on the same principle. The guest arrived at the front door, where he was greeted and arrangements were made for his lodging and food. A stable for horses and carriages, or a compound for camels and cargo, were provided at the rear of the establishment. A rear yard was used by the innkeeper's wife and her assistants to prepare food which was then cooked in a kitchen. We therefore had a house divided in two. The front half of the house included the reception area and the public rooms, or the covered arcades in the caravansaries, where the guests gathered to dine and to socialize. The other half of the house, or to use a term which is still applicable, the back of the house, was where food was prepared and where the guests' service amenities were taken care of, such as laundering, the shoeing of horses, or the repair of harness and traveling gear. This duality of a hotel must be thoroughly understood by an architect before pencil is put to paper to start the design. For convenience's sake and for ease in preparing a preliminary study, we will assume that all these services take place on one level. Figure 1 indicates the flow of services and hotel personnel. For the time being, we will ignore the actual rooms and concern ourselves only with the level where the "greeting" takes place and where the services are rendered. The "greeting area," for future reference, will be known as *the front of the house*, and the place where services occur will be known as *the back of the house*. It must be borne in mind that, as far as planned circulation is concerned, there must never be a mingling of the front-of-the-house services with those of the back of the house. At no time should the guest be aware of everything that is taking place at the back of the house, but, at the same time, the smooth operation of the front of the house is completely dependent upon what is taking place at the back of the house. The two functions must be kept separate and yet so interrelated that both function smoothly and efficiently.

Hotels are designed and built so that the client, owner, or operator of the hotel will get a satisfactory financial return on his investment. In order to achieve the greatest return for each dollar invested, we again face a dual problem. In the first instance, the guest must feel completely comfortable and at ease from the moment he steps through the entrance doorway, checks in, goes to his room, avails himself of the food and beverages available,

spends a comfortable night in a well-appointed, scrupulously clean room, and returns the next day to a room which is as fresh and inviting as it was the moment he first entered it after checking in. Everything for the guest's creature comforts should be carefully considered, whether it be the ease of finding the registration desk, the cashier, the bars and dining rooms, the elevators that will take him up to his room, and finally the room itself. The service at the registration desk, in the bars and dining rooms, and in the guest room itself as well as in the corridors must be such that the guest finds his every want courteously and efficiently taken care of. The physical environment becomes an important part of the guest's creature comfort. These factors include color and decor, lighting, proper air temperature, comfortable furnishings and, above all, a pleasant and relaxed atmosphere.

Everything that the guest expects and should get will be a result of what takes place at the back of the house. It is only in this area that everything that will keep a guest contented during his stay is arranged for and so ordered that everything the guest is seeking is accomplished unobtrusively and, what is most important, economically.

Economic operation of a hotel depends entirely upon the back-of-the-house services. Since these services are primarily concerned with hotel personnel, the plan must be so arranged that maximum efficiency from each hotel employee can be achieved without taxing the employee and without allowing the guest to feel the drive for efficiency that dictates every phase of hotel planning.

HOTEL ECONOMICS

The economics of a profitable hotel venture brings us to the third duality of which the architect should be extremely conscious or aware during every phase of the planning stage. This involves the economics of a new hotel, which will center upon the cost of construction and furnishing. These costs represent, together with the cost of the land, the amount of money that is to be invested. They are the base upon which the hotelier will figure his financial return. A rule of thumb devised many years ago by a prominent hotel architect still seems to be a sound rule to follow. At that time, it was stated that for every dollar of income per room, \$1,000 should be spent in the construction of that room. We must bear in mind, of course, that when we speak of a room we are speaking figuratively, with the knowledge that the cost of a room would also carry its proportionate share of every other part of the structure, such as the hotel lobby, the dining rooms, the bars, the corridors, the offices, the laundry, the kitchens, and all the other facilities that will be found in a hotel. Using that rule of thumb (that is, \$1 income per \$1,000 invested), a room that costs \$10,000 to build should bring in \$10 for a night's lodging. Unfortunately, with rising costs of operation, this balance of \$1 per \$1,000 will not always hold, but it is still a good rule of thumb. With hotel rooms now going at from \$10,000 to \$40,000, we find that a \$10-

per-night room is a rarity and an average of \$20 and \$30 is more common, while luxury hotels run as high as \$40 and even \$50 per night's lodging. From the above, it becomes obvious that the architect should know approximately what type of hotel his client wants, as expressed in terms of cost per room per night, in order to establish some sort of rough budget for the cost of the hotel. At this point, it should be pointed out that we are talking of cost of construction, which does not include furnishing and equipping the hotel. Another fact which does not really affect the planning of the hotel but which the architect should be keenly aware of is that preopening expenses are sizable. They are, in fact, a part of the original investment and should be charged to cost per room. More will be said of this at an appropriate place.

The second part of the financial consideration in the design of a hotel is the cost of operation. We now know what it will cost to build the hotel, and so some sort of preliminary budget becomes feasible. The architect may not know what it will cost to operate the hotel, but he should understand every facet of hotel operation and develop his plans to achieve maximum economies in the operation of the hotel. This includes the hours spent by such personnel as maids, porters, housekeepers, chefs, cooks, dishwashers, laundry workers, bellmen, receptionists, bookkeepers, reservations clerks, banquet managers, and executive staff. If we would, for a moment, think of a hotel as a plant which turns out a finished product, we would think of the finished product as the creature comforts of the guests (bed and board) and of the kitchens, laundries, and service areas as the machines. The hotel personnel would be the workers who operate the machines in order to achieve a fine product at the lowest possible cost. With these thoughts in mind, we can now take up each facet of hotel operation—front of the house and back of the house—which will be discussed in detail and illustrated with diagrams and drawings so that each part of the jigsaw puzzle which forms a hotel can be fitted into place to achieve a smoothly functioning, pleasingly desirable, and financially profitable operation.

First let us clear up the question of preopening expenses, which should be considered as a part of the total cost of the hotel. Before a hotel is put into operation—in fact, months before the first guest arrives—certain hotel personnel are employed who will eventually be charged with the operation of the hotel. Such employees would include a manager, a chief chef, a controller, an advertising and/or a public relations firm, and an engineer who will be operating the mechanical equipment of the hotel. These people will usually be found on the site of the hotel under construction anywhere from six months to one year before the hotel is completed. Their salaries are part of preopening expenses. Another factor in preopening expenses would include stationery and other supplies that various key personnel will need before the opening of the hotel as well as, ultimately, the cost of hotel stationery, typewriters, bookkeeping machinery, and

office supplies. Another preopening expense will be a cost allocated for opening ceremonies, which often include cocktail parties and banquets for people from the news media and civic organizations as well as for civic authorities. All these costs are considered preopening expenses. One other item that must be considered in preopening expenses is the training of the personnel that will service the hotel. This will include maids, housekeepers, chefs and cooks, waiters and waitresses, and front-office and clerical personnel. There also will be others, such as maintenance men, bellmen, and porters. These can add at least 30 percent to the construction cost.

Another facet of costs, which the architect may or may not be involved in, involves furnishings for the hotel. In this category will be found not only the actual beds, dressers, chairs, tables, and floor coverings in the guest rooms but also the furnishings, floor coverings, special lighting fixtures, and decor items needed for all public spaces. These fall into the categories of lobbies, dining rooms, bars, cocktail lounges, coffee shops, meeting rooms, banquet rooms, and a host of other facilities which will be found in hotels.

Another large portion of the costs which normally would not be a cost of construction would be the equipment for all kitchens and bars as well as the equipment, if such a facility is to be included, of laundries and valet service. Going further, we will need lockers for employees and other amenities for the service personnel.

Finally, we come to a group of items which will include glassware, china, silver, pots and

pans, linens, pillows, and uniforms for maids, bellmen, waiters, etc.

When we lump preopening expenses together with all the items enumerated above, we will find ourselves adding anywhere from 50 to 75 percent more to the actual construction costs. All these figures will not influence the budget for construction, but it would be wise for an architect designing a hotel to be conscious of these additional expenditures.

BACK OF THE HOUSE

Though rarely seen by a guest, the back of the house is the most crucial part of the plan. It must be laid out with two paramount objectives: control and efficiency. Foodstuffs, housekeeping supplies, and a great many other items must be received out of sight of the hotel guests. Such receiving is usually done at a loading dock, which should be covered so that deliveries can be made regardless of the weather. An operating hotel, even a small one, will have deliveries going on throughout the day. The receiving of shipments as well as the checking of whatever comes into the hotel and, finally, sending the various items received to their proper destination must be under tight control. This is usually the function of a receiving department that should be located directly on or adjacent to the loading dock. Tight control must be exercised in two directions. In one direction, it is not uncommon for material to be delivered and, within a short time of its having been left on the dock unchecked, for the management to find that this material has

disappeared or that some parts of the shipment have gone astray. The second part of the control is to make sure that, once these shipments have arrived, they go directly to their destination without a chance of becoming lost on the way. As an example, let us say that a shipment of liquor is delivered to the hotel. It is a very simple thing to pick up a case and remove it from the loading dock before the receiving clerk has checked the shipment through his control point. It is also a very simple thing to have a case of liquor disappear on its route, once it has been checked in and before it gets to the liquor storage room. This type of pilferage will apply not only to liquor but to almost every item, including linens, foodstuffs, and even items of furnishings. A good back-of-the-house plan will be worked out in such a way that the flow of supplies is tightly controlled by the security that the architect works into his plan. Another example will suffice: It would be poor planning to have a valuable item such as liquor carted through a passageway and past an employees' locker room on its way to the liquor storage room. It would take but a moment for a case to disappear from the cart into the locker room. A tight, well-planned back of the house will have circulation patterns that will provide the utmost in control. It is this type of planning that is definitely the province of the architect. There is one further item in the control area which, at first glance, might seem highly unimportant: namely, the movement of garbage out of the hotel to a point where it will be picked up by garbage trucks. Experience has indicated that a good deal of pilferage in hotels is accomplished through

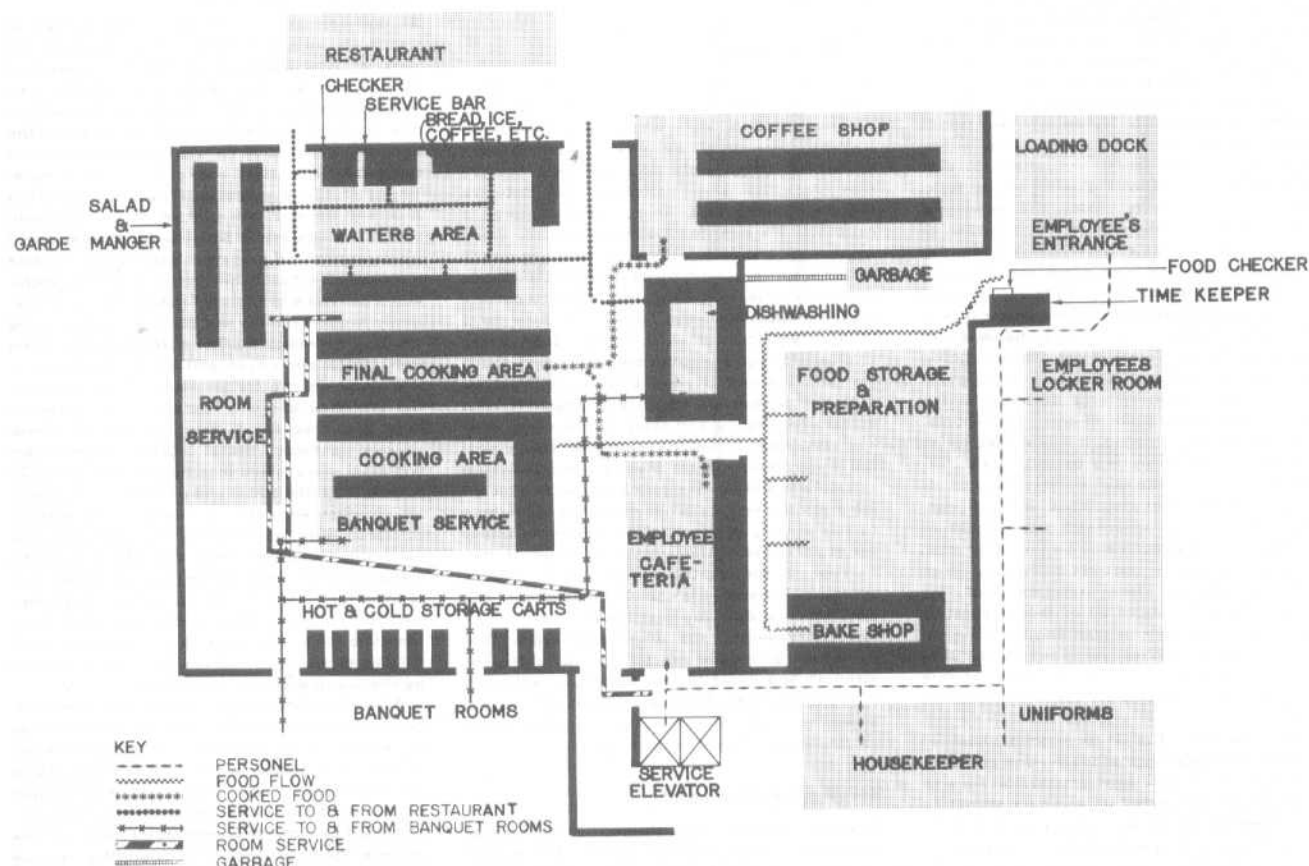

Fig. 1 Flow diagram of service areas.

the medium of garbage removal. Well-wrapped steaks and cans of food can be concealed in garbage and removed by an accomplice before the garbage haulers pick up the refuse. In the larger hotels, garbage destructors or compressors may be used, in which case tight surveillance is necessary only in the garbage receiving area. Where garbage is shipped out, it is wise to have the garbage rooms so placed (and, incidentally, refrigerated) that the receiving office has this space in full view to discourage an outside accomplice or an employee who is leaving the hotel from entering the garbage room to filch what was placed there previously by someone in the kitchen or the supply areas.

Another form of control which must be exercised and which becomes a part of the architect's planning is the flow of personnel into and out of the hotel. Hotel personnel usually come through at a point close or adjacent to the receiving area. This is not necessarily a must, but it is advisable because the same control office can observe the coming and going of the help. Usually time control is through the medium of a time clock, which is punched by the employees. It is not uncommon for thieves to attempt entry through the service area and to work their way up through service elevators to accomplish what they came for. A tight control at the point of entry and egress of all employees is highly desirable and can easily be accomplished if it is the same point as that at which food and other hotel supplies are brought in. Once again, the architect's careful planning will make it possible for employees to reach their various dressing and locker areas with a minimum of travel time lost. It must be borne in mind that there is class distinction in hotels and, as an example, that dishwashers and porters are not placed in the same locker rooms as head waiters and reception clerks. The distinction here is far from a fine line. The mix of hotel employees will be dictated by the hotel operator, and he may determine whether waiters and bellmen are to be placed together or separated. Maids and waitresses may or may not be in the same locker room, depending on the hotel operation. Locker rooms should be provided with ample toilet facilities and showers. Once the personnel have changed into their uniforms, the plan of the back of the house will make it possible for the people to get to their work stations with little time lost. Maids and porters will want to get to service elevators along the shortest possible route. Chefs, cooks, and dishwashers should get to their work areas without going through long, tortuous passages. It is usual to issue uniforms in an area as close to the locker rooms or the point of entry as possible. In this phase of planning, it should be borne in mind that uniforms are usually under the control of the housekeeper, so that the proximity of the uniform issuing room to the housekeeping department becomes a most important consideration. It should also be borne in mind that the housekeeper controls soiled and clean laundry as well as clean uniforms ready for reissue. The interplay of all of these activities will dictate a finesse in planning to bring all these activities together and to achieve as little loss in time and motion as possible. At this point, let us sum up this portion of the back of the house.

A flow diagram (Fig. 1) for a typical back of the house will indicate that the service entrance is located out of view of the main entrance to the hotel but has direct access to a street or road capable of handling truck traffic. The loading dock should be protected from weather so that food, laundry, and supplies will be off-loaded and stored and not get rain-soaked

while waiting to be checked in. All personnel will enter the hotel at this point. At least two small offices will probably be located here, one for the steward (or receiving clerk) and another for the timekeeper. Outside the steward's office there should be a floor scale to check the weight of produce as it enters. If the food storage and preparation kitchens are located on a different level, a sidewalk lift or conveyor belts should be provided. The timekeeper will check the employees in and out and help to discourage those who may be tempted to steal. Immediately past the timekeeper, the employees should be separated into two different traffic flows, one for the food service personnel, the other for everyone else. Once food service personnel enter their traffic flow, they should have no contact with either guests or other house personnel with the obvious exception of waiters. All this is simply a matter of security. If there is any deep dark secret of successful hotel service design, it is a built-in security system, which is a direct outgrowth of the architect's plans.

Uniform issue is related to the housekeeper, the housekeeper to the laundry room, and the laundry room to the soiled linen room. The soiled linen room connects by vertical linen chute to the service room on every typical floor, and every typical floor is connected by a service elevator that opens to the lower-floor service area convenient to the scrutinizing gaze of the steward and the timekeeper. For convenience, a trash chute (Fig. 2), going from every typical floor service area, should be located next to the linen chute. This will force an arrangement where the trash room is close or adjacent to the soiled linen room and both of these are near the service entrance for ease in pickup.

Laundry Facilities

A laundry is a usual adjunct of most good-sized hotels. Many hotels avail themselves of city laundry service, in which case there is no laundry room at all or only a small laundry which handles towels only. A hotel laundry that does its own uniforms and flatwork (sheets, pillowcases, linens, etc.) requires a good-sized space for washers, dryers, drum ironers, and various pressing machines—each suitable for its own type of flatwork, uniforms and guests' laundry, and men's and women's wearing apparel. If the laundry is done by a laundry service out of the hotel, then items like towels require a comparatively small space for washing and drying, since only washers and fluff dryers are necessary, together with an area for folding and stacking the clean towels. Larger hotels will maintain their own cleaning department for dry cleaning and pressing of woolens and similar garments. Such a cleaning and valet service is usually a part or close to the laundry area, and it is definitely under the supervision of the laundry manager. It may be that, in the not-too-distant future, experiments with disposable sheets, pillowcases, and uniforms will do away with laundry services in hotels. Presently, the disposable types that have been produced are still not of sufficient strength and durability for hotel use, although the future may produce exactly that. At present some "no iron" linens are in use, thus eliminating some of the large ironers.

Housekeeping Department

The housekeeping department, having several functions, is the province of the chief housekeeper, who will usually have assistant floor housekeepers. Under the housekeeper's strict

control and supervision will be all the maids and porters. These people, after donning their uniforms, will come to the housekeeper for instructions and very often for supplies to take with them to the various guest-room floors. The porters will deliver to the service areas on the guest-room floors all linen and soap as well as facial tissue, toilet paper, matches, room service menus, and ashtrays. (Most hotels use inexpensive ashtrays that carry the hotel name and that the guests may take along as souvenirs.) The housekeeper's area is also a storage area, for here are kept all the supplies that become a part of housekeeping. Aside from such obvious things as a stock of linen, paper goods, soaps, etc., the housekeeper will carry in her warehouse storage area additional lamps (which are easily broken by guests) and small items of furnishings which are easily removed or destroyed. In the housekeeper's department there will usually be a place for a seamstress to mend those sheets, pillowcases, and drapes that need repair. It might be useful for the architect to know how many rooms a maid can make up during her daily tour of duty. In some areas unions control the number of rooms, and it may be as little as 12 per maid. It rarely goes beyond 15. One porter is usually assigned to each maid. In addition to the regular daytime maid, there will be, in most hotels, a night maid who will make up beds for guests ready to go to sleep. This entails the removal of the bedspreads, straightening of the room, the supplying of additional soap, toilet paper, etc., all for the guests' convenience. One night maid usually can handle twice as many rooms as a day maid handles.

Food and Beverage Service

We have now taken care of the bed portion of the "bed and board." Now let us examine the "board" part of a hotel service. The *board*, of course, refers to the old English trestle table where guests took their meals. In the earliest hostels, the innkeeper's wife took care of the cooking, maids took care of the serving, and a large board or table sufficed for the guests. Today's food operation is a highly complicated one, and an architect should be familiar with the entire operation. Most hotel kitchens and food preparation areas are planned by experts known as kitchen engineers. It is not the architect's province to plan a kitchen, but it is certainly helpful for the architect to have a good working knowledge of what takes place in the food preparation area and in the kitchens. It will make for better communication between the architect and the kitchen engineer when they are discussing the planning of these spaces. Just one word of caution—each expert will want more space than the plan can possibly allow. They don't *really* need that much space. The kitchen engineer will conjure up visions of irate chefs stalking off the premises, but experience has indicated that the architect's knowledge of what the requirements are will temper the demands of the kitchen engineer. Let us follow the flow of the raw food from the time it is delivered to the steward until it is finally cooked and ready to be picked up by the waiters or the waitresses.

After the comestibles have been weighed in, checked, and signed for, they are sent to either dry storage or liquor storage (a room with a big lock on it) or to one of the various cold holding rooms or boxes. Canned food and other bottled or packaged food which does not need refrigeration will be sent to dry-storage rooms. In this storage space will also be kept the various condiments that the chef will need in the preparation of his food. Vegetables will be sent to

an area where they will be stored ready for preparation. A refrigerator box of the proper temperature will be needed, as well as work space, sinks, and cutting boards where vegetables will be prepared for the chefs as needed. The peeling of potatoes, cleaning of carrots, trimming of lettuce, etc., are done in the vegetable preparation area and not in the kitchen area. Dairy products will go to their own cold-storage boxes. Fish, fowl, and meat will go to a separate area where boxes must be arranged with proper temperatures for their storage. Some of these items will be kept frozen, others in aging boxes, and others in simple cold storage. Fish preparation needs its own space. The hotel, in its purveying department, may buy cut and trimmed meat or portioned meat and fowl. In the latter case, only a storage area is necessary, since no preparation takes place. Where a hotel does its own butchering, it is necessary to know what size cuts the hotel intends to buy (halves, quarters, etc.), and it may be necessary to provide ceiling rails to transport them. Once again, it must be borne in mind that all these facilities are under tight control. Once the food has safely reached its destination in the rooms just described, there must be no place for it to go except into the kitchen where it will be used by cooks and chefs. Freezer, refrigerator, and cold storage boxes require heavy insulation. Slab sinkages in these areas should be provided for. If this is not done in advance, then boxes will be set on top of the slab, therefore requiring a ramp from the work area to the box. This is something that is far from desirable in a smoothly functioning kitchen. If the architect is not fed this information before construction starts, it may be necessary to depress the entire slab in this area and then, after the boxes have been placed, use fill to bring the working area up to the level of the boxes. At this point, a word or two should be said about the bakery facilities. The bakery shop should be a separate entity, having its own refrigerator boxes as well as all the pertinent equipment that a baker will use in his art—and an art it is, indeed. The baker will be called upon to bake not only the everyday bread and rolls and the run-of-the-mill cakes and pastries but also unusual designs in birthday cakes, wedding cakes, etc., and he may often be asked to carve ice figures for elaborate food displays or buffets. Here again, one should be reminded that the bakery should be close to the actual food service area so that not too many of these goodies find their way into the locker rooms or out of the hotel entirely.

We now have everything delivered, prepared, and ready for expert transformation by cooks, chefs, and *garde mangers* who will be preparing soups, ragouts, roasts, epicurean sauces, and *hors d'oeuvres*.

Let us take a walk through what would be an ideal kitchen, assuming that everything is happening at one level. (See Fig. 3.) The food brought in from the various prep areas consists of fish, meat, fowl, vegetables, and condiments. The food from the prep area is brought to the various points where it is to be used. One of the first areas to which a good part of the prepared food will go is the rough cooking area. Here we find the big soup kettles, the vegetable steamers, the ovens, and the hot tops where most of the bulk foods will be prepared. Since many large pots are used in this area, there is usually a pot washing area close to the rough or preliminary food cooking area. Rough cooking is usually backed up to the finished cooking area. In this finished cooking area, the chefs will be preparing sauces and gravies as well as broiling and frying and applying final flame to various types of meats, fish, and fowl.

Between the chefs' ovens, broilers, and fry-

Fig. 2 Trash or linen chute.

ers, which are aligned in a straight line, there will be an aisle for the chefs. On the other side of this aisle will be the serving tables from which the waiters will pick up the finished food. At the bottom of these tables will be plate warmers which the waiter picks up and sets on the table so the chef can place the order of the specific dish that is required. Also on this table will be *bains-marie*, which are pans im-

mersed in circulating warm or hot water into which are put already prepared vegetables, gravies and soups, all kept at the proper temperature, so that the chef can ladle the required portion of food onto the dish where he has already placed his steak, broiled fish, fried food, or other entrée. Above this long serving table will be small pots and pans which the chef will take down and use to prepare the

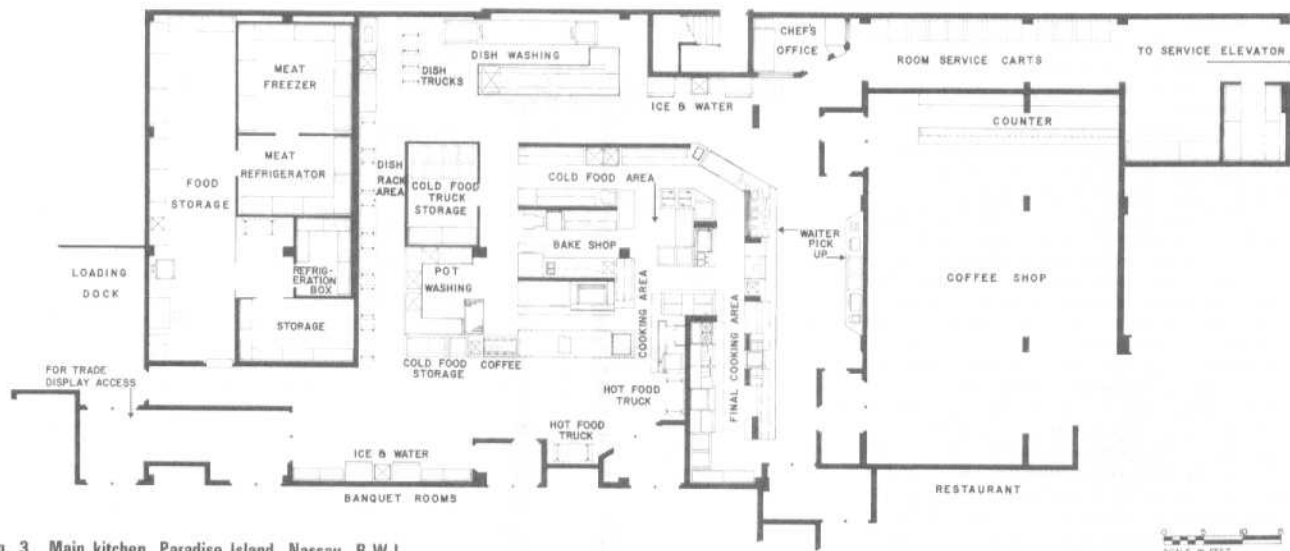

Fig. 3 Main kitchen, Paradise Island, Nassau, B.W.I.

small portions of whatever food is called for on the waiter's order. This food preparation area will have reach-in boxes for cuts of meat and fish which have been prepared and are ready for the final stage of cooking. The chef reaches in and takes out what he needs to prepare the required dish. Off to one side, somewhere in the waiter's line of traffic, will be the *garde manger* section. Here have been delivered all the prepared vegetables and fruits so that the *garde manger* can arrange salads, prepare cold desserts, and work up the various types of hors d'oeuvre as well as seafood cocktails and other cold items for the start of a meal or salads that accompany the main dish. The *garde manger*, on special occasions, will prepare special trays of cold, exotic dishes used for buffets or banquets. He will have his own reach-in boxes for all the types of fruits, vegetables, seafoods, garnishes, etc., that are used. Farther along the waiter's course will be a section, close to the exit, where such items as bread and rolls, butter, coffee, tea, ice, and other items are stored. Bread and rolls may be in a roll warmer. Here also will be found the coffee urns, toasters, and egg boilers. This entire area is for self-service by the waiters, who will pick up the items they need on their way to the guest waiting for the delivery of his food. Now let us, for a moment, leave the kitchen and go into the dining room. A bus boy has picked up the soiled dishes after a guest has completed his meal. He brings the soiled dishes into that kitchen area which is allocated for dishwashing. In some cases the waiter will pick up his own soiled dishes and deposit them in the dishwashing area. This is a very noisy operation in which sound should be carefully baffled; but because of the need to get the dishes from the dining room to the dishwasher, the dishwasher is usually placed close to the dining room area so that the dishes can be disposed of as soon as the waiter or busboy enters the kitchen. The dishwashing area is, of necessity, not only noisy but also a rather untidy operation, so it must be kept fairly isolated from the actual cooking and serving area. The reason for keeping it within the kitchen is obvious since the dishes, as soon as they have been properly cleaned, will be brought back into the kitchen area for the service of freshly prepared food. The waiter, coming into the kitchen, places his orders and follows a definite path along the cooks' and chefs' serving

tables, the *garde manger's* serving tables, and the pick-up area. Then, before entering the dining room, he will usually go by a checker's desk where he presents a check indicating the items that he is taking out of the kitchen to the diner. A checker controls all foods and beverages leaving the kitchen area to make sure that the items are correct and the prices properly indicated. One other space will usually occur in our ideal kitchen—a service bar with a bartender who will prepare the drinks that the waiter has ordered. Here again, it must be on the direct path of travel, so that after the prepared drinks have been picked up by the waiter, he will pass the checker, who will check off the drink items as to quantity and price.

Before leaving the kitchen, we must look at some other areas that we will usually find in our ideal kitchen. There will be a chef's office, which is set where the chef can observe all the activities in the kitchen. His office is usually enclosed with glass to give him aural privacy but complete visual control. Here the chef will prepare and plan menus. He will be placing orders for food and will generally be operating a rather complicated and meticulous part of the hotel service. In addition to the chef's office, there may be two other areas (once again, assuming that everything is happening on this one level). The first of these is the room-service area. Here there must be sufficient space for a fairly large number of room-service rolling tables, which are set and ready to carry the dishes that have been ordered by the guest via telephone. These tables are usually set up with their linen, glassware, and silver. In the warming compartment below the tablecloth, the room-service waiter will place the hot dishes, and on top of the rolling service table he will place the cold dishes. The room-service area is always close to the cooking and *garde manger* area. Much of the room service will consist of breakfasts or sandwiches and salads. Wherever a hot dish is called for, the room-service waiter will pick it up at the chef's cooking area. The room-service area should, of necessity, be as close to the service elevators as possible. These, of course, must come down to the kitchen from the service areas on each of the guest floors. Normally, we will find a room-service operator, who sits at a telephone taking calls from the guests. These calls are especially numerous in the morning, when many guests

are calling in for their breakfasts rather than coming down to the dining room. The cooking area, consisting mainly of griddles, will be manned by short-order chefs who are ready to prepare various hot breakfast dishes, and the *garde manger* section will be manned by a crew who are expert in the preparation of breakfast menus. For the rest of the day, sandwiches and salads coming from the *garde manger* will be most in demand. Another part of the kitchen will be devoted to the banquet area. We are assuming that this hotel is not too large and does not require a separate banquet kitchen but rather a banquet serving area. We will see again that the chefs will prepare the banquet food, managing their schedule so that it does not interfere with lunch or dinner. In the banquet area there will be mobile cabinets that take trays. These are electrified cabinets arranged to keep dishes either hot or cold. These banquet cabinets can be stocked before a banquet for certain types of menus. In other instances, where steak and roast beef are on the banquet menu, there must be areas in which the chef can broil the steaks or large ovens where a number of roasts can be prepared at the same time. A large banquet area in a hotel will require a separate banquet kitchen with its own cooking facilities as well as its own dishwashing area. Here the architect must review the food service requirements and, working with the kitchen engineer, determine the location of the banquet cooking and service area. Very often the banquet facilities are not on the same floor as the dining rooms, in which case there would have to be an elevator connecting the main kitchen with the banquet area.

Let us have one last look around. To begin with, because of what is taking place in the kitchen, the floor should be of some material which can be easily cleaned. In the past, the better kitchens used ceramic tile. There are many new types of floor preparations which can be applied directly over the concrete slab and which lend themselves to easy cleaning as well as offering a firm foothold to prevent slipping on wet spots. The walls, in most kitchens, were usually ceramic tile. Here again, the new plastic materials are by some standards even better than tile, with its cement joints and the possibility of spalling tile. By all means, every effort should be made to hold down the noise level in the kitchen, and this is best ac-

complished by using a perforated metal ceiling with acoustic batts above or a ceramic-treated acoustical material. Hoods over all cooking areas are a must, and the architect should check with the building code to see that the hoods conform with the standards not only of the code but also of the National Fire Underwriters to prevent the spread of fires which often occur when a dish flames up while cooking. One last observation: it is an excellent idea to have toilets and washrooms for kitchen help, so that it isn't necessary for them to return to their locker rooms, which may be at some distance. It is always advisable to keep the kitchen help within the kitchen during their stint of duty. Doors to dining rooms, and there may be several dining rooms serviced by the one kitchen, should be strategically placed and baffled so that the diners do not have a view of what goes on in the kitchen, and, what is more important, do not hear what is going on.

Most hotels have coffee shops, although the trend in many hotels today is to work out an arrangement in which a coffee shop and a restaurant are combined. This is especially true of the smaller hotels and of some of the chain hotels. For purposes of discussion, let us consider that the coffee shop is a separate entity. The ideal plan would be to place the coffee shop backed up to the kitchen, so that certain finished dishes and prepared foods can be delivered to the coffee shop work area directly from the main kitchen under complete control as it passes from prep areas to kitchen to coffee shop. In the coffee shop much of the food preparation will be done at the counters. In this area there usually will be found sandwich and salad areas as well as fryers and broilers and griddles. Also in the coffee shop will be the cold area for ice creams, desserts, etc. In the larger coffee shops, most of the cooking may be done in the kitchen and passed through to the counter for pickup by waiters and waitresses. In a coffee shop there will, of course, be counters and stools, but there will also be tables and chairs. At the counter we will usually find a pickup area where the waiters can pick up the food prepared for them without disturbing the diners who are sitting at counters. Dirty dishes will be sent back to the dishwashing area through a pass-through, or they will be carried to the dishwashing area in the main kitchen. Coffee shop diners expect quick service and, toward this end, the menus are carefully prepared for easy handling by short-order chefs and sandwich and salad men who work within the coffee shop and not in the main kitchen. Wherever specialty dishes of the day are offered, such as ragouts or soups, they are prepared in the main kitchen and placed in hot *bains-marie*, ready to be picked up for quick service.

There is another phase in the food area which may or may not be considered in a hotel, namely: food service or dining for the hotel help. Larger hotels will provide an employees' cafeteria. This space is usually planned to be close to the help's locker rooms and yet contiguous to the main kitchen. If such a plan can be worked out, the food prepared for the employees' cafeteria comes from the main kitchen, and it is served as it would be in any normal cafeteria. Employees go through a self-service line, picking up hot and cold foods as well as drinks as they go along. They are checked by the checker or cashier and carry their trays to the tables. Attention should also be paid to the fact that the dirty dishes which come out of the employees' cafeteria must be returned to the dishwashing area and here again, if at all possible, a pass-through should be arranged

whereby the dirty dishes can be passed directly to the main dishwashing area in the kitchen.

While still in the food department, let us look in on the beverage service area. This may be a bar room or a cocktail lounge. In any case, there will be a bar with stools (if local codes permit) and an area for cocktail tables and chairs. A cocktail lounge must be serviced just as the kitchen is serviced. To the bar must be brought not only liquor and bottled goods but also the usual crunchies that one finds in a bar, such as potato chips, peanuts, pretzels, etc. The bartender will also need from the commissary area oranges, lemons, limes, tomato juice, etc. Cocktail lounges will also serve cocktail canapes and, very often, sandwiches. Arrangements must be made in the plan for the delivery of all of these items to the bar without too much possibility of losing something on the way. Ideally, the delivery should be made directly to the back bar through pass-throughs from the kitchen, so that we find once again another unit backed up to the ideal kitchen. This will not always be possible.

There is a great deal more to be known about full food and beverage service in a hotel, but a general knowledge on the part of the architect will suffice. He must depend upon the kitchen engineer for advice, plans, and details, just as he must depend upon his electrical engineer, his mechanical engineer, and structural engineers to feed him the information that he will need to complete his plans for a hotel. It must be borne in mind that most hotels consider food service as a necessary evil. The percentage of profit on a food operation is always very small. Profit on beverages is much higher, and so beverage service is quite desirable as an adjunct to a food operation. A well-planned food and beverage setup, where control and efficiency are the guiding principles, will increase the rather meager profits on this hotel function. It is in this area that the architect, working with the hotel operator and his staff of experts—which includes chefs, managers, etc., as well as the kitchen engineer—can bring to bear his talents in creating an entity which will function at top efficiency.

Mechanical Spaces

Another area that should be considered in designing the back-of-the-house spaces will be the boiler or mechanical room. In this area will be found the various pieces of equipment for heating and cooling as well as all the tanks and pumps to keep all the mechanical systems in operation. Each mechanical room will be of a size and shape that will satisfy the requirements for all the creature comforts that a modern hotel has to offer. In this area will also be found all central switch gear that controls electric current for every purpose in the hotel complex. This domain belongs to the house engineer and, naturally, there should be provision for an engineer's office, with a mechanical repair shop close by. There are a number of other shops that probably will be located in this area of the hotel. These would include a carpentry shop, an upholstery shop, and definitely an area for a locksmith. Somewhere in the area, where they are easily accessible, will be storage rooms in which will be kept a multitude of spare parts to service the hotel. Some of this storage space will be used for mechanical equipment replacements, and other storage areas will contain spare parts for the furniture, carpet replacements, wallpaper replacements, cleaning materials, and cleaning equipment that will be used by the house porters.

There will be another area which, technically, belongs to the back of the house. This area will

be occupied by personnel that very often come in contact with the guests, and the strategic location of these back-of-the-house facilities will be controlled entirely by what happens in the front of the house. Included in these areas you will find accounting and bookkeeping offices (which back up the front cashiers); reservations offices (which back up to the front registration desk); and offices for management, which will include a reception area, a manager's office, and an assistant manager's office. In this part of the hotel complex one would usually find the head of the food and beverage department, who may double as the banquet manager. There will be a mail sorting room, which might well be placed behind the registration desk, since guests' mail is delivered at this point. More will be said about all these spaces when front-of-the-house operation is discussed further. Before leaving this area, we should note the fact that there will probably be a secretarial pool to handle all the spaces that have been enumerated above. We will be referring to all the above spaces as the *administrative area*.

FRONT OF THE HOUSE

We have now established the activity which controls the plan of a hotel as far as the back of the house is concerned. We will now examine what happens in the so-called "front of the house"—that area which concerns itself with the guest as distinct from that area which concerns itself with the smooth functioning of the hotel. It must be borne in mind that a hotel, like Janus, wears two faces. The guest or the paying customer sees only the front of the house, and this must be all that he desires—a wish fulfillment, an ego builder, a status symbol, and above all else a pleasant and satisfying place in which he will spend a night, a week, or a month. The back of the house, which has already been discussed, is where all that makes this happen takes place. These are the areas of burnishing, butchering, baking; of boilers, motors, compressors, and ovens. The guest never sees all this, but these unseen spaces will precisely determine his degree of contentment. These are the areas that will ultimately dictate whether the hotel will run at a profit or a loss. The front of the house comprises every area that the guest will see; lobbies, dining spaces, rest rooms, passenger elevators, corridors, hotel rooms, etc. These spaces must be handled and planned with one thought in mind: the convenience and continued approbation of the guests.

Let us now accompany our arriving guest from the time his car or taxi pulls up to the main entrance. As the guest enters the main entrance (and there should be only one main entrance), he should be overcome with a feeling of serenity, welcome, and definitely a complete absence of confusion. The registration desk and the elevators should and must be immediately apparent. The registration area consists of a front desk, behind which is a registration clerk, behind whom is the key and mail rack, and behind that the various administration spaces. At this point let us consider the registration process itself. (See Fig. 4.)

Guest Registration

A hotel registration desk must be located so that it is immediately visible as one enters the hotel lobby. The size of the desk will be determined by the size of the hotel. There is no special rule to be followed except that a hotel of let us say, 2,000 rooms might have anywhere

Fig. 4 The Churchill Hotel, London.

from four to six registration clerks, while a hotel of 100 to 200 rooms will have one or at most two spaces at which guests may register. There are certain requirements for the clerk behind the desk as far as equipment is concerned. The simplest arrangement will call for a suitable file containing advance reservation cards requesting space, so that the clerk can quickly check what room has been reserved for what particular guest. Another mandatory piece of equipment is a slip or card file which, at a glance, indicates which rooms are occupied and which rooms are open. Occupied room spaces will have a card with the name of the guest and probably the date when the guest intends to leave. As soon as the guest checks in, a card is slipped into the space for the room, indicating that the room is now occupied. This, the simplest form of registration, is applicable to the smaller hotels. Larger hotels have far more sophisticated equipment, much of it electronically controlled, which serves to indicate time of arrival of guests who have made reservations, time of departure of guests who are already checked into the hotel, and systems whereby the registration clerk can also be informed whether the room has been vacated and whether the room has already been made up by the maid on the floor and is ready to receive a new guest. The architect should acquaint himself with the requirements of the front desk and also be aware of certain companies who manufacture the filing systems and the electronic equipment which is used for reservation and guest control.

Advance Reservations

The hotel industry depends primarily on advance reservations to keep its rooms filled. The traveling public is aware of this fact, and most travelers will book their reservations in advance. Chain hotels and chain motels have developed complicated and efficient electronic systems for advance reservation bookings which are made from any point within the chain. The systems employed are very much like the systems now being used by airlines for bookings and reservations. Terminal points in the larger hotels have automatic electric equipment which types out the name, date of arrival, anticipated length of stay, and type of accom-

modations requested. Whether the system be the involved electronic system or whether it be a reservation made by telephone or wire, a reservation clerk within a reservation office in the hotel will take care of all these requests for rooms. Since questions do arise at the time when the guest is checking in, the location of the reservation office must obviously be as close to the front desk as the plan will permit. This will enable a reservation clerk to go back to the reservation department to check on a questionable reservation or to adjust any problems which may arise at the time that the new guests are checking in.

Mail and Keys

There are two other services that the front or registration desk must perform. The first and obvious one is to serve as the place where the room keys are kept. Some of the larger hotels have room-key clerks whose functions consist only of receiving keys from guests as they leave the hotel and giving the incoming guests, either upon registration or during their stay, the keys to their rooms. If the registration clerk handles the keys, then obviously the key rack is directly behind the desk, easily accessible to the registration clerk. If the hotel is large enough to require a separate area and separate personnel for handling of keys, this function will usually be alongside the actual registration desk. Since it is comparatively simple for someone to ask for a key who is not entitled to it and who may be using that key to enter and rob an absent guest, it behooves the architect to realize that some control is necessary in the handing out of keys to make sure that keys are given only to the registered guests for that particular room. Mail is also handled in most hotels at the registration desk, which dictates that keys and mail slots are designed as one unit and placed directly behind the registration desk. Where a hotel is large enough to require special key clerks, the same clerks will probably handle all incoming mail for the guests. If at all possible, mail sorting and handling should be done in an area where the guest does not see this operation take place. Ideally it would be behind the mail and key rack. A well-designed unit will be worked out so that a mail clerk can place the mail into the individual

mail slots from behind, rather than working in the front and interfering with the activity of the registration clerk.

Cashier

The average hotel usually has the cashier's counter located adjacent to the registration desk. There is no hard and fast rule concerning this close interrelationship. The larger hotels may place cashiers in the so-called "front desk" area but somewhat remote from the actual registration desk. There are times in large hotels, especially those catering to conventions, where one convention is checking out while another is checking in. This will make for traffic congestion and some confusion. Such a situation can be avoided by planning the registration and cashier facilities so that lines forming in front of the registration desk do not conflict with lines forming at the cashier's counter.

The cashier in the smaller hotels will handle most of the bookkeeping. This is done by means of today's quick and efficient electric bookkeeping machines. Very often the night cashier will handle a good deal of the bookkeeping, relieving the daytime staff of this chore. Larger hotels will have a complete bookkeeping department. This will require more than just the actual cashiers, who remain at their stations, while the bookkeeping department handles all entries and bookkeeping for the guests. It is obvious that this bookkeeping department should be close to if not backed up to the front desk cashiers, so that any questions of charges can be quickly checked and adjusted by the cashier, who will contact the bookkeeping department for clarification or corrections in the guests' bills.

Conveniences will usually be found in the cashier's area for guests who bring valuables with them, whether it be cash, jewelry, or important papers. Guests are requested by hotel management to leave such valuables in the hotel's safe deposit boxes or vault. It is desirable to have the guest transfer his valuables to a cashier out of sight of the public occupying the main lobby. Therefore, a small closed room is normally provided. The guest enters this room and gives the valuables to the cashier through a pass-through window. This pass-through window should have a view of the vault or the safe so that the guest can watch his valuables being deposited properly. Where safe deposit boxes are furnished by the hotel, the cashier will hand a key to the guest. The same procedure will be followed when the guest wishes to withdraw his valuables from the safekeeping of the hotel. This convenience is especially useful in large resort or convention hotels where women guests will be wearing jewelry on special occasions. A closed room makes it possible for the guest to deliver and receive the jewelry without being observed, a precaution that is most necessary in today's theft-prone society.

A hotel cashier must also handle the cash from restaurants and coffee shop. The cashiers in these facilities will be bringing their cash receipts to the central cashier. In a small hotel, this can be done directly without any concern about the transfer of the funds from the restaurant and coffee shop to the cashier. In large hotels, where there are a number of restaurants and other facilities which entail cash payment, special arrangements should be made for the handling of this cash and, in some instances, safety deposit boxes or vaults are provided so that the money can be stored when it is brought to the cashier space at off hours and held until

normal cashier operations begin in the morning, at which time receipts from the night before are taken out and properly credited. This system is very much like a night depository in a bank. More and more hotels are installing pneumatic tube systems for the transfer of guests' checks directly to the cashier. These checks will be coming from various dining rooms and cocktail lounges as well as from the coffee shop and from the room-service area. These checks for food, beverages, etc., which have been signed by the guests, should be transferred as quickly as possible to the cashier. This is especially important when a guest is checking out a short time after having signed a check for food or beverages or such items as laundry and valet. Charges for telephone calls will have to be forwarded to the cashier also. Many hotels are using an electric counting device visible to the cashier which indicates the number of calls made by the guest while occupying his room. These indicators function automatically but must be supplemented whenever long-distance calls are made by guests. Such supplemental information is fed to the cashier by the telephone department.

Administrative Area

The administration of a hotel operation depends entirely upon its size. A small hotel will most likely have an office for a manager, who may have his secretary working in the same room with him. The door to his office faces the public lobby, and an additional door is provided so that he can go from his office to the front desk. This is the simplest operation and is found only in the smaller hotels. A larger, medium-sized hotel will have a manager and an assistant manager and, as a rule, there will be a reception office where one or two typist-receptionists will be acting as a buffer between the public and the manager. As a hotel project grows larger, the administrative area grows more complex. Aside from the manager and the assistant manager, there may be an office for a food and beverage manager and a banquet manager. A larger hotel, with sizable convention facilities, will also have an office for the convention manager and his assistants. Obviously, as the complexity of the office and administrative area grows, a more careful and detailed study is, perforce, made to arrange a smoothly functioning suite of administrative offices together with secretarial pools, bookkeepers, teletype machines, a mailroom for incoming mail and for voluminous outgoing mail, etc. The accompanying illustrations show how these areas have been handled in various hotels. It must be borne in mind that this front of the house works closely with the back of the house. Many of the people in the administrative area will deal with guests as well as hotel customers seeking to arrange for luncheons, banquets, and conventions. Accessibility to the public, therefore, is of the utmost importance.

Restaurant Facilities

Every hotel, whether it has 50 rooms or 2,000, must consider the feeding of guests. Small hotels may get by with a pleasant coffee shop restaurant. This type of unit is becoming more popular in the smaller hotel where feeding facilities are kept to a minimum. Such a facility would be the type where quick coffee shop service could be offered a guest, either at a counter or at a table, and where, within the same space, more leisurely dining could be provided. The difference between the two is achieved primarily through decor and atmosphere rather than any physical or struc-

tural arrangement. In such a facility, it is possible to take care of a large breakfast business using the entire facility. There are occasions when a visual separation between coffee shop and restaurant is made movable, so it can be taken away during the breakfast-hour rush. For luncheon, the division is reestablished, making it possible to serve quick meals for those in a hurry in the coffee shop area and more leisurely luncheons in the restaurant portion. In the evening, it is possible to get a more permanent type of separation between coffee shop and restaurant by pushing the coffee shop separator around the counter area, thus allowing for maximum table and seating arrangements in the so-called restaurant area when the coffee shop is doing a minimum business. Under normal situations there will be a cocktail lounge or beverage bar even in the smallest dining facility. The larger hotel will have a pleasant coffee shop for quick service and for simpler meals, whereas a restaurant, with its appropriate decor for more leisurely dining, will offer a more varied menu with probably higher cost per meal than in the coffee shop. The cocktail lounge will usually be found close to the dining room so that hotel guests can pause for a cocktail before lunch or dinner, or while waiting, before going to the dining room, to meet friends or other guests. Where convention facilities are offered within a hotel, it is wise to have a bar placed close to the convention facilities. Conventioneers seem to have a propensity for a cocktail before or after meetings. This impulse-type of beverage buying is boosted tremendously if beverage facilities are placed in the normal path of traffic. Large convention and banquet facilities usually provide a fixed or portable bar arrangement in the preassembly or foyer areas to take care of pauses between meetings and seminars and to fill those pauses with a facility that will provide a "pause that refreshes." There is no special requirement for the design of hotel restaurants, bars, cocktail lounges, and coffee shops which are in any way different from the standard requirements for any such facility. Attention is called to the fact that people staying at hotels have a tendency to seek out highly touted specialty restaurants within an area rather than eating their meals in the hotel. This is especially true for evening dining. Toward that end, hotels more and more are turning to specialty restaurants whose specialty is not only food but also decor, so that they can compete favorably with individual restaurants in the general area of the hotel. The same hotel kitchen can prepare almost any type of special food including Chinese, Polynesian, seafood, or gourmet dishes. The important thing to remember in laying out these spaces is that the decor must be developed to entice the hotel guests to eat in the hotel rather than outside in other specialty restaurants. Continuing in this vein of specialized feeding, some hotels are installing rooftop restaurants where a view of the city or the general area is available and in which fairly limited menus are offered—mostly open-hearth kitchen service which includes steaks, chops, and cuts of roast beef. Such a menu requires a very small kitchen and obviates the need for creating large, expensive facilities on a roof for specialty cooking. Wherever a rooftop restaurant is created, the architect must bear in mind that there will be increased traffic in the elevators taking diners from both in and outside the hotel to this specialized rooftop facility. And don't forget that, because of public assembly requirements, the stairs must be sized larger. Supper clubs or nightclubs will also be found in the larger hotels. When faced

with this type of dining and entertainment feature, the plans must include not only a stage of sorts, together with the attendant stage lighting, but also dressing rooms for performers and a room for the orchestra. It is highly desirable to keep such an adjunct as close to the main kitchen as possible. In the planning of large hotels that encompass all the dining facilities already mentioned, it may not be possible to operate out of one central kitchen. In this case there may be several kitchens, preferably on a horizontal core, so that there is the possibility of vertical distribution of food from the preparation areas which would probably be on the lower level.

Lobbies

Every hotel, regardless of its size, must have a public lobby. The size of the lobby is largely determined by the number of guest rooms as well as by the type of hotel that is on the architect's drawing boards. It goes without saying that the larger the hotel, the larger the lobby. The lobby will also have to be larger in a resort or convention hotel. A resort hotel will require a large lobby because guests will congregate there in the evening. A hotel catering to conventions needs a large lobby because here again there is a constant gathering of conventioneers before they go off to lectures, seminars, meetings, luncheons, and dinners. There is no rule of thumb to determine the size of a lobby. One must proceed by making a careful study of similar types of hotels and arrive at decisions after discussions with hotel operators and managers. A hotel lobby sets the mood for a hotel. This space, more than any other, will create the first and usually the most lasting impression. Furnishings, color, finishing materials, lighting, and decor must create the proper ambience regardless of whether the hotel is large or small, in a city or a resort, moderately priced or expensive. The interior designer plays a most vital part in planning and designing hotel lobbies.

Elevators

Except for one- and two-story motels, every hotel and motel will use elevators to take guests from the point at which they have checked in up to the floor where the guest's room is located. Elevators should be located so that they are immediately visible, either from the entrance of the hotel or from the check-in or registration area. Another consideration in the planning of elevators is that of their location on the guest-room floors. It is advisable to place them centrally so that the distance walked by a guest in any direction is reduced to a minimum. It would obviously be wrong to place the elevators at the end of a long corridor. It would be far better to have these elevators placed so that they are about midway between the two ends of the guest-room corridor. The number, size, and speed of the required elevators is best determined by the elevator companies themselves. It would not be wise for the architect to make a determination as to these factors. Elevator companies can give the answers when facts and figures are given to them, and it is they who will inform the architect what the number and size as well as the speed of the elevators should be. Most elevator companies are computerizing this information and can furnish it to the architect within a matter of hours. The designer should bear in mind that the elevator is part of the hotel atmosphere and, just as it is important to create the proper ambience in the lobbies, it is important to create and to carry out this

pleasant feeling in the elevators, since they are the transitional points from lobby to guest-room floor.

Under no circumstances should guest elevators be used for service. Service elevators are separate and apart. Many hotel designs indicate the service elevators within the same general area as the passenger elevators, but this need not necessarily be so. Each bank of elevators should be strategically located to best service the front of the house (guests) or the back of the house.

Before leaving the subject of lobby design, attention is called to the location of the bell captain's station. The bell captain's station should be located so there is a commanding view of the hotel entrance, the registration desk, the cashier, and the elevators. If the hotel is to render the proper kind of service, it is up to the bell captain to see that the arriving or departing guest is properly taken care of. He must see to it that there is a bellman or a bell-boy available for the luggage going into the hotel and the luggage going out of the hotel. Incidentally, this is also a form of safeguard to see that guests departing the hotel stop at the cashier and take care of their bills before leaving. The bell captain should have at his disposal a storage space for small parcels which may be left for absent guests and which he will eventually deliver when the guests return to the hotel. Somewhere in the lobby there should be a rather large storage space for luggage which may be left by guests after checking out but prior to departing. In very active hotels with a high occupancy, there is a mandatory check-out time. Very often the guest is not going to leave the hotel until several hours after the check-out time. Under those circumstances, the guest will leave his luggage with the bell captain after checking out, but he will remain in the hotel until it is time for him to depart via his car or to the railroad terminal or airport.

Guest-Floor Corridors

We will now accompany our guest from the elevator to the guest's room. As the elevator doors open, the guest should find himself in an area which can be designated as an elevator foyer. This may be a large open space or a space slightly wider than the corridor itself. Whatever its size, it should, by its width, denote the fact that it is the elevator foyer. It is wise to remember that no guest-room doors should be placed opposite the elevators. Guests coming or going late at night, coming out or getting into the elevators, may talk loudly or may be too noisy, in which case they would be disturbing guests whose doors open off this area. The foyer should be further demarked from the guest-room corridor by its decor and lighting. It is always a thoughtful touch to have certain appurtenances which indicate consideration for the guest in the total overall planning. One of these appurtenances would be a small bench or some type of seat for guests who may want to wait in the foyer for the elevator or who may be waiting to meet someone else on the floor. It is also a thoughtful gesture to have a full-length mirror in this area; men as well as women guests appreciate the chance to have a look at themselves before descending to the main lobby floor. There should obviously be a good-sized ash receiver for cigarettes, cigars, and other trash nuisances that the guest may want to get rid of before getting into the elevator.

The guest-floor corridors are transitional spaces between the public space, which has already been discussed, and the guest room,

which will be discussed further below. The first problem the architect faces is a question of dimension—width and length. Let us consider the advisable length of a corridor first. Good practice indicates that a corridor should, if at all possible, not be over 100 ft in length. It sometimes occurs that, because of the size of the hotel or its configuration, corridors may be longer. There are a number of hotels where corridors stretch out for over 200 ft. The architect would be well advised to introduce an interruption of some sort in his corridor planning to keep the guest from feeling as if his approach to his room were an endless path. The interruption may be by means of a change in dimension or, if the plan permits, a change in direction. The long look of a corridor may be relieved by means of appropriate lighting and decor. Where a corridor turns at right angles or at any angle, it would be well to arrange for a secondary foyer effect to give the guest a second breath, so to speak, before continuing along the corridor to his room. There is very little choice in the width of a corridor. Normally, 6 ft is considered an adequate width, although some hotels have made do with only 5 ft. This could well suffice if the corridor was a rather short one. Another expedient, which may be used either in a narrow corridor (under 6 ft) or a standard-width corridor, would be the device of recessing the bedroom or guest-room doors. Setting doors back from the corridor wall 1 ft or even as much as 2 ft gives an apparent width to the corridor and, what is more important, it gives each room entrance its own sense of privacy and individuality. It is normal to pair guest-room doors and therefore the recess or door alcove would normally be the width of two doors or a minimum of 6 ft and a depth ranging anywhere from 6 in. to 2 ft. An expedient that always helps a corridor to appear shorter is that of creating a change in the colors of the recesses, which under ideal conditions would be opposite each other on either side of the corridor. If this is possible in the plan, and it usually works out that way, a break in the carpet color or design in this area as well as a change in the color scheme for each entrance-door alcove creates a pleasant feeling of pause or interlude along a long corridor. Lighting will also play an important part in making corridors seem more interesting and less stretched out. Illuminating the alcove areas is always a pleasant device. In the first place, it makes the numbers of the doors immediately visible, and in the second place, it gives the guest a sense of comfort to know that no one could be lurking in the door alcove where deep shadows might hide him. Lighting always creates an ambiance of hospitality, and lights would be best placed in these door alcoves. This is not a hard and fast rule. In many instances, the interior designer or the architect may decide that lighting along the blank wall between the guest-room doors would serve his purpose better. All this, of course, is a matter of individual taste as well as of the wishes of the hotel operator. Another small but important factor is the design of the guest-room door itself. A flush panel door is the least expensive but also the least desirable type of door for a guest room. If only a flush door is used, strong color might be helpful, or the use of natural wood finishes would be pleasant. If at all possible, some form of decor on the door will create a sense of inviting hospitality for the arriving guest. Another thing to be borne in mind is that the guest must be able to recognize his room number, and such a room number might well be an attractive decorative adjunct in this area. Some hotels have used room numbers placed to the

side of the door rather than on the door itself. Here again, the ingenuity of the designer comes into play. It is not the intention of this dissertation to discuss color, but wall covering and wall colors in corridors are most important. It must be borne in mind that along these corridors pass endless numbers of pieces of luggage carried by the guest or the bellboy. Luggage may also be transported by means of trolleys. In any case, the lower portion of the wall will be subjected to brutal abuse by being banged with luggage or trolleys. The lower portion of the wall, therefore, might well be designed as a dado made of a bruise- and shock-resistant material or merely marked off with a contrasting color or wall covering. Thus the lower walls in the corridor can be repainted or repapered when they have been sufficiently scuffed while the upper walls may remain as they are. This can result in considerable savings to the hotel operator.

Guest Rooms

Everything that has been said about hotels thus far may be considered peripheral to the prime product that a hotel has to offer, namely, the guest rooms. This is the final product that is to be sold. In connection with this thought, it is well to remember (although this may not have any influence on the planning or the architecture of a hotel) that, unlike an item on a merchant's shelf, a guest room that is not sold one night means a complete loss. It would be as if a grocer were forced to throw out each day's unsold supply of boxed cereal and to lay in a fresh supply every morning. That is a precise analogy to the situation of the hotel man and his guest rooms. The room that is not sold and the revenue that is lost can never be recovered (Fig. 5).

Now let us have a look at the guest room itself. The first consideration is that of size. The accompanying illustrations of guest rooms in hotels designed by the authors show as wide a variety of dimensions as an architect may encounter. For the moment, let us eliminate the space taken by a bathroom and a closet and consider the actual room itself. The length and width are determined by the amount of furniture that is to go into the room and by the degree of luxury that the hotel operator wishes to achieve. Let us consider the latter first. It is an obvious truism that the luxury of space is an expensive one when considered in the light of construction costs. Space, however, does convey a feeling of luxury and, where an operator is aiming for the high-priced market, it would be well to create rooms that are sized not for the actual furniture requirements but for the sheer luxury of spaciousness.

And now to the first premise—namely, what furniture should go in and what size room should accommodate the furnishings. In order to understand furniture requirements, it is important to have a knowledge of the various types of rooms that a hotel or motel offers guests. The most common room in the hotel field today is the twin-bedded room. Then we have the possibility of a single occupancy room, and, lastly, studio rooms or suites. The twin-bedded room, the most common in hotels generally, will vary in length depending on the type of bed that the operator wishes to install. The smallest unit will have a pair of twin beds. The first question that arises in considering twin beds is whether there will be a night table between the beds or whether the two beds will be placed side by side. Rooms containing twin beds, with a night table between them, are preferred by most hotel operators because there are many double occupan-

cies that do not necessarily involve married couples. For instance, the occupants might be two women, two men, or one adult and one child, and in these instances it is always desirable to provide separate beds. As an example, two men traveling together would much prefer to have their beds separated than to sleep side by side. Economy in space and length of room can be achieved by placing beds side by side, but although such an arrangement is often used, it is not the best one.

The next consideration is the size of the beds themselves. There are single beds which are 3 ft 6 in. wide, a full-sized bed which is 4 ft 6 in., a queen-sized bed which is 5 ft wide, and a king-sized bed which is 6 ft wide. Presently, all beds are still being made in a 6-ft 6-in. length dimension. Since the average American is growing taller and taller, it would be wise to consider 7-ft beds as a standard, since it will not be long before such beds will be introduced into most hotels. One reason for the queen-sized bed is the comfort of the guests. Many guests would appreciate the extra width of a queen-sized bed, and it is possible for families traveling together to have an adult and a child sleep in the same bed. Where king-sized beds are employed (and this will be found most often in motels), two adults may occupy one bed, so that a two-bed room may take a family of four people.

In connection with beds, it is wise to remember that the headboard, which seems like an anachronism in home furnishing, is a most important feature in hotels. Guests like to read in bed, and because of the widespread use of hair preparations, the headboard portion of the bed is subjected to heavy wear and soiling. Whether a headboard is provided or whether some other device such as a flat cushion against the wall or any other ingenious arrangement that the interior designer may come up with is used, headboards are definitely a part of hotel equipment. Beds, as a rule, come on glides or coasters in one form or another so that they can be moved when the maid comes in to make up the beds. Movement of beds is most important, so that maids and porters can clean under them. Nothing is more disturbing to a guest than to look under a bed and see an accumulation of carpet fluff and discarded cigarette butts.

Now that we have discussed beds, we know that we must have at least 7 ft 6 in. from the wall to the front edge of our newer anticipated 7-ft beds. If at all possible, there should be a 3-ft aisle and, if no furniture is placed opposite the bed (a very unlikely arrangement), then the width of the room would be a minimum of 10 ft 6 in. Where furniture will be placed on the wall opposite the bed, such furniture will most likely consist of a dresser or cupboard with drawers. Such a piece of furniture requires a minimum of 18 in. in width and most likely an optimum width of 24 in. It must be remembered that drawers have to be opened, and the guest will need room to stand in front of the dresser to open the drawer without being forced to sit down on the bed while doing so. Therefore, a 3-ft aisle again comes into play. If we consider the 7 ft 6 in. required for the bed, 3 ft for the aisle, and 2 ft for the dresser, we have an optimum room dimension of 12 ft 6 in. between walls. This is a minimum dimension, and if the plan and the budget permit, another 6 in. would be a most welcome spatial device.

Let us now consider the length of the room. This dimension will vary depending upon the types of beds used—queen, king, or standard twin—but this is only part of our consideration. It is necessary in each room to provide not only sleeping facilities but also sitting facilities.

The most common arrangement found in most hotels consists of two comfortable armchairs with a cocktail table between them. A comfortable chair will require a depth of least 30 in. and another 30 in. of leg space in front of it, which means that we need at least 5 ft from the wall before we encounter the first piece of furniture, which will probably be a bed. The furniture placement will usually call for the chairs to be placed against the window wall. The reason is obvious. A view out of the window is a pleasant experience for someone using the guest room as a sitting room. In connection with the so-called cocktail table, this may give way to a low table which may be used for dining, card playing, or writing. Many so-called "cocktail tables" are, in effect, pedestal standing lamps which combine two pieces of furniture in one: the cocktail table and the standing lamp. Such an expedient is a space saver, since the light is exactly where it is wanted and there is no need for another movable lamp. In talking of lighting, we must bear in mind that we want not only a lamp or a ceiling fixture over the sitting area but also adequate reading lights for the beds. The most often used arrangement is a twin-headed lamp sitting on the night table between the two beds. Far from enough study has been done in this type of lighting, which would make it possible to give adequate and direct light for one guest who is reading in bed while the other guest can sleep without being disturbed by the light of his roommate. Lights may be placed over the headboards, but this means that two outlets may be required and certainly two luminaires instead of one.

Another area that will need good lighting is the area which we will call the writing and makeup area. This is usually some sort of table arrangement where a guest may sit and write or where a female guest can sit down and apply her makeup. It has become rather standard to combine the dresser with its drawers with another piece of furniture which is called the dressing-writing table. This type of case goods is most often used, but it is by far the least desirable for a well-appointed room. Another piece of fixed furniture that is desirable is a luggage stand. Many hotels overlook this useful piece of furniture and supply folding luggage stands. These will serve adequately but, since the guest will usually leave his piece of luggage in the room, it is far more desirable to have a pleasant piece of furniture than a folding luggage rack. Before leaving the furnishing of the standard room, it should be noted that there should be at least one more chair in the room. This could be a straight-backed chair or a stool placed in front of the writing-makeup table. This will provide for three sitting pieces. If at all possible, a fourth chair should be considered. It is far pleasanter to have four people sitting on chairs than to have three people supplied with chairs while the fourth visitor or guest has to sit on one of the beds. Between a pair of twin beds, the ubiquitous nightstand with its small storage space below is standard. A clever interior designer can improvise and create far better furnishing arrangements than the standard nightstands—arrangements which will give the room additional storage space. The cocktail table which has been previously mentioned may well give way to a dining table, which will serve the purpose far better because it can be used for setting down a drink or a book or a package and also for serving a meal (rather than depending upon the room-service trolley). In connection with the room-service trolley, the designer should bear in mind that if a dining table is not provided, there must be sufficient space in the room to set up a room-service table. This is wheeled in

by the waiter, and it must then be possible to arrange at least two and sometimes more chairs around it for the guests who wish to dine in their rooms.

The luggage stand has already been mentioned, but at hotels where the guests may be staying for as long as a week or more (this obviously will be the case in resort hotels), the designer should bear in mind that they will come with more than one piece of luggage. Some travelers carry four and six pieces, and where to put them in the standard room becomes a serious problem.

Lighting in the room, which has been partially covered, will depend upon the interior designer. The necessary luminaires have already been discussed, but these may be supplemented with additional light to create a pleasanter ambience in the room. The control of these lights must be carefully considered. The simplest type of control will call for a switch at the door which will turn on one or two or even all the lights in the room. Most hotels and their designers give entirely too little thought to the switching arrangement for the control of lights. This leads to confusion on the part of the guest, who has to explore the room and decide which lights are controlled at their source. A great source of annoyance is the arrangement in which all the lights are controlled by one switch at the door and then each luminaire has its own ON and OFF switch. It presents an annoying and puzzling problem to the guest coming into the room or the guest who wants to turn out the lights when going to sleep. This problem has been solved in many hotels by placing one light switch at the door to turn on one of the lights and then providing a battery of light switches at the bed which control the other lighting in the room. If this is not carefully thought out, a fuming guest will often comment that one has to be a lighting engineer in order to understand how to work the intricate switching arrangement. This is especially true if two-way switches are used, one at the door and one at the bed; then you may be sure that the guests will become quite thoroughly confused. Such switching arrangements are prevalent in European hotels, but there the problem is overcome by using graphic symbols on each switch to make it possible for the traveler to figure out the intricacies of the light controls. Here we can give no advice other than to consider the problem carefully as if it were a problem in logistics.

Thus far we have been speaking only of guest rooms with normal twin- or single-bed arrangements. Another popular arrangement in hotels is that of the so-called "studio room." Dual sleep pieces have been developed which are comfortable sofas during the day and perfectly comfortable beds at night. In this context we are not speaking of the folding sofa beds. These should be used only as a last resort in hotel furnishings. They can never achieve the comfort of the standard bed. The dual sleep pieces we are talking about come in various ingenious arrangements, but they are primarily beds which have some back-up arrangement so that they become normal sofas when used for sitting. When they are moved out, rolled to a side, or adjusted in some other way to clear the backrest, they become full-width, full-length beds. The accompanying illustrations show some of the ways in which these dual sleep pieces may be used. The purpose of a studio arrangement is to enable the guest to use his room as a true sitting room. Many travelers use their rooms during the day to conduct business or to visit with friends. Obviously it is much pleasanter to sit in a room which looks like a living room than to ignore

the beds, which may or may not have been made up when the guest receives company. Another reason for having these studio rooms is that they may double as sitting rooms for suites by having one room, which is a normal bedroom or guest room, adjoin another room which is furnished as a studio room. Thus the hotel can provide a two-room suite (obviously, connecting doors must be provided between these two accommodations). Before leaving the question of adjoining rooms, the architect should determine with the hotel operator how many rooms will have adjoining doors. Too often the planner decides that all rooms should have interconnecting doors. These doors are a source of annoyance because, unless the finest type of sound barriers are used on them, these doors become a nuisance in that sound will travel more easily through doors than through walls. This is true in spite of the fact that a good installation will call for one door in each room, so that actually every connecting opening has two doors. Wherever the budget permits, a high-rated door is desirable, and if at all possible, a gasketing device should be employed to cut the sound transference from one room to another. With regard to sound transference, the mechanical plans must indicate that base outlets and telephone outlets may not back up to each other. This is one of the most troublesome ways of transmitting sound from one room to the other. It is economical to back up electrical and telephone outlets, but it is a bad policy in hotels. Outlets should be staggered to avoid sound transmission. The architect should definitely consider the decibel rating of his wall construction to try and cut sound transmission from one room to another. This usually adds to the cost of the hotel, but it is highly desirable. As one guest once said, he is tired of answering his phone when it is his neighbor's that is ringing; and as another guest once complained, every time his neighbor flushes the toilet, he runs for the hills. Sound transmission is a nuisance in hotels and it should be carefully considered by the architect.

Every hotel should have arrangements for suites of a permanent nature as opposed to a combination of a studio room with a typical guest room. Suites will be furnished like fine sitting rooms. They are used not only by the affluent traveler because he can afford it but also by travelers who do a good deal of entertaining, especially business travelers who entertain clients and customers on their arrival in any given city. If a hotel offers convention facilities, it will require an inordinate number of suites. Conventions will mean that there will be a good deal of entertaining going on, and companies whose representatives are guests in the hotel will want good-sized suites for fairly large cocktail parties and other forms of entertainment. These large suites, incidentally, may double at times as seminar or conference rooms. In this context the hotel may be asked to move most of the furniture out of the suite living room and bring in seminar chairs for meetings. If such will be the case, the planner should provide for a storage room on each floor capable of holding alternate types of furniture to suit the requirements of guests using large suite-sitting rooms. These suites are also often used by two couples or by a large family, in which case the sitting room of the suite may be used for sleeping at night. In this case, dual sleep pieces will be required, but they will usually be the type that is referred to as a "davenport," or the type of sofa which opens out to become a comfortable double bed (never as comfortable as a true bed). These suites should have a good-sized dining table with a sufficient number of chairs, provision

for an adequate desk (since some business may be carried on in that room), a sufficient number of comfortable lounge chairs, and an accessory table. The decor of the room will depend upon the interior designer and the hotel operator, who usually knows what he would like in these suites. It is a good practice to arrange the sitting room of a suite so that it connects with at least two bedrooms and, if at all possible, three and sometimes even four bedrooms. This will require some intricate planning. Suites will usually be found in the corner of a building, which makes it possible for the planner to join up several bedrooms.

There are times when suites are not used, and the hotel should be able to rent each of the rooms in the suite separately. This means that each room will have its own separate key. A foyer which connects the bedrooms and the sitting area makes this separate keying of rooms possible. A single door or a pair of doors leading to the foyer of the suite will be on one key, but by opening these doors temporarily (the plans should be devised so that the doors can be swung back and out of the way), the foyer becomes part of the corridors and each room, including the sitting room, would have its own key. This makes for maximum flexibility, so that the sitting room can be rented on an individual basis. A complete bathroom should be planned for each of the sitting rooms of a suite to make it possible to rent the rooms out singly. Even if the room is not rented singly, a bathroom or lavatory facility certainly is needed in each living room or sitting room of a suite. Plumbing connections might well be arranged so that a bar can also be introduced in the sitting room. Since this room will be used for entertaining (either business or private), a bar with water connection becomes a pleasant adjunct.

There is a growing tendency in hotels and motels to create greater flexibility in meeting and seminar rooms that would be available to conventions. These rooms are so designed that they can be used as bedrooms when not required for meetings or other purposes when a convention is in the hotel. Under this concept usually two rooms are divided by a foldaway partition, so that the two rooms can be thrown into one if a larger room is required. On other occasions, the one guest room may be used for very small meetings without being opened up to the adjoining guest room. In view of the fact that these rooms are designated for meetings, whether singly or in pairs, their furnishings are different from those of the standard guest room. At the outset it must be determined that this will probably be used as a single room rather than a double room. The bed itself is placed in the wall. It is the type that swings up and is hidden in the wall. There are a number of manufacturers today who are making these hideaway beds, which are quite satisfactory for hotel use. It is possible, if so desired, to have two hideaway beds, in which case the room becomes a double room. The rest of the furniture is carefully considered so that it can be moved out of the way to open up the room for meetings or, at best, is sized so that it will not interfere with meetings in these rooms. Obviously, these rooms will be placed on the lowest floors so they can be close to the public spaces for the convenience of those who are going to use them for meetings or seminars in connection with a larger convention or meeting taking place in the hotel.

Guest Bathrooms

We are now ready to review the bathroom requirements in a hotel. The minimum bathroom will have a combination tub-shower,

a lavatory, and a water closet. Since the traveling public is very conscious of bathroom accommodations, the architect should give a good deal of thought to this feature in the hotel. The accompanying plans of the writer's projects show various arrangements of bathroom accommodations. An innovation devised by the writer's firm was the introduction of two lavatories in the bathroom facilities. These two lavatories may be right in the bathroom itself, they may be pulled out into a dressing area, or one lavatory may be placed in the bathroom and another outside the bathroom. This last arrangement is most desirable, so that if two people occupy a room, regardless of whether it is a husband and wife, two men, or two women traveling together, they have the use of the bathroom facilities without interfering with each other. It immediately becomes obvious that if, for instance, the husband is shaving, the wife can be taking a bath or shower—and other possibilities are immediately self-evident.

European hotels invariably have not only the tub, water closet, and lavatory but also a bidet. This is a particularly European custom, and we are finding that in many hotels in America the bidet is being introduced. Obviously, this additional feature is found only in the most luxurious hotels. Taking the water closet as the first of the fixtures in the bathroom, there is one word of caution. A noisy flushing toilet is a disturbing noise element not only to the occupants of the room but also to the occupants of the adjoining rooms. Flushometers are not desirable because they are noisy. There are noiseless flushometers, but they are quite expensive. The average hotel uses a silent tank-type of toilet as the most expedient type of water closet for hotels. A wall-hung unit makes cleaning of hotel bathrooms easier for the maid, but again, its economics will determine whether this fairly expensive type of installation is warranted. The tub in a guest room is normally a 5-ft tub. A good hotel installation will go for the additional expense and the additional dimension by installing 5-ft 6-in. tubs. The European hotels invariably have at least a 5-ft 6-in. tub, and there are many luxury hotels with 6-ft tubs. The normal shower head becomes standard in all hotels, although there is a growing tendency to using the so-called "telephone shower head." This is a hand-operated shower head which is more common in Europe than it is in America. Manufacturers of bathroom equipment have devised a hand-held shower head which operates as well as the normal wall shower head, and by using two movable shower-head supports, one at the normal hand level and one at the higher level where a fixed shower head normally would occur, the guest has the option of allowing the hand-type shower head to remain in a standard position or to remove it and use it as he pleases. This type of shower head, incidentally, is also convenient for women guests washing their hair.

Recently, most bathroom fixture companies have been turning their attention to some form of fiber glass or plastic tub and shower arrangements that can be delivered either in one piece or in several sections. This eliminates the necessity for the use of tile or other imperious wall material in this area. These one-piece installations are still in the early stages of development, but eventually hotels will be turning to them for economy in construction and for simplicity in installation. The standard one-piece lavatory is fast disappearing from hotels. Instead, a lavatory is becoming a shelf arrangement into which the bowl is sunk. Usually, a marble slab with a cutout to receive the lavatory bowl is used. There are many

companies manufacturing synthetic marble that make the bowl and the ledge in one piece. This is highly desirable in hotels, but care should be exercised to make sure that the synthetic material can withstand cigarette burns, alcohol stains, and the general abuse that these areas get. Older hotels used to have ice-water connections in the lavatory. This is now a thing of the past because most hotels provide ice makers in corridors as a nice touch for the guests, who can fetch their own ice cubes for cold water or for cold drinks.

Another consideration in a bathroom is the so-called "medicine cabinet." Since guests really do not carry medicines any more, it is advisable to eliminate this facility entirely. If a medicine cabinet is used, very often a guest will place shaving materials, lotions, etc., in the cabinet and upon leaving the hotel forget to look in it, therefore leaving behind his or her toiletries. It is preferable to have a ledge on which toiletries may be placed, where they are conveniently reached, and where, obviously, they will not be left when the guest checks out. There are a number of appurtenances that will be placed in the washing area, such as a tumbler holder or toothbrush holder, but here again the tendency is to leave out these pieces of hardware, although a receptacle for toilet tissues is desirable and should be included. If a ledge is used, the toilet tissue holder can be placed within the recess of the ledge, as can be the tumbler holders and the toothbrush holders. Obviously, an electrical convenience outlet must be placed in this area for electric shavers, electric toothbrushes, and other electrical gadgets that today's traveler takes with him. A slot receptacle for used razor blades should not be forgotten.

Towel bars must be strategically placed so that the guest can reach for a towel regardless of whether he is stepping out of the tub or whether he is washing or shaving at the lavatory. A well-run hotel should keep an ample supply of bath towels and face towels in each guest room, and sufficient space for these should be allowed together with the necessary hardware arrangements. Hooks are often omitted, but these are necessary for a guest's pajamas or bathrobe. Of course, the ubiquitous bottle opener should not be forgotten. We still have bottles with bottle caps, although in the near future this will probably be an interesting anachronism. Another nicety which might be provided is some form of clothesline. With today's wash-and-wear apparel, many guests, especially women, like to do their washing at night and hang their garments in the bathroom. Since this has become a way of life for the traveler, an architect will be well advised to seek out one of the many tricky self-concealing wash lines on the market today.

Finally, the treatment of the walls and floors of a bathroom becomes the province of the interior designer. The use of tile, for one reason or another, is being reduced to a minimum. It will be found around the bath enclosure (where the new one-piece units are not used) and usually on the floors because they are so required by sanitary building codes. There are many new materials on the market, and such old materials as thin-slab marble may be used. Where code permits, some hotels are actually using washable synthetic carpets in bathrooms for floors. The walls are definitely no longer tiled, but some form of scrubbable wall covering material is prevalent in most hotels today. It need hardly be said but it should be noted that *good* lighting is an essential in a bathroom where men will be shaving and where women will be applying makeup. This, together with ample mirror services, is an indisputable must. A number of hotels are installing a wall-hung

mirror which is an enlarging mirror on one side and a normal mirror on the other, a very nice touch for both men and women guests. Much has been said about the bathroom, but Americans are a bathroom-conscious people. A hotel designer should realize that pleasing the guest is his prime purpose and that the bathroom can be a great guest pleaser.

Guest Room Closets

We now come to the final requirement in the guest room, namely, the closet. The size of a closet will be determined by the type of hotel. Obviously, such an accommodation in a motel is of little use. Most motels expect guests to stay only overnight, and therefore they need very little accommodation for hanging clothes. Many motels, in fact, have no closets at all but provide a neat hanging space to make sure that the motel guest who likes to check out early in the morning does not forget any clothes in the closet, which might be closed when he is leaving. Having the open hanging arrangements obviates this possibility. The longer the guest-room stay that is anticipated, then the larger the closet. The larger walk-in closet should certainly be considered where guests will be staying for any length of time. This is especially true in resort hotels, where the guest will be arriving with many pieces of luggage and the closet should be large enough to accommodate the emptied luggage during the guest's stay. It should be possible to store the luggage out of sight in the closet without diminishing the available hanging space, the shoe-rack space, or shelf space for hats and other apparel and paraphernalia. Whether the closet is a flat reach-in type or a walk-in type, the door should be such that, when the closet is opened, there are no hidden recesses where clothing may be forgotten because it cannot be readily seen by the departing guest. Another thought to be borne in mind is that closet doors can become a nuisance when opened, and their strategic location to avoid banging into open doors is definitely the province of a hotel planner. A good closet will have a hang rod with sufficient space to comfortably hold men's and women's clothes, a shelf for packages, hats, etc., and a shoe ledge or rack for placing shoes. A walk-in closet must, of course, have a good source of light. A reach-in closet should also have light outside the closet so that the guest can see what is inside.

Guest-Floor Service Space

Every guest-room floor will have a service area. A service area serves several functions. Primarily, it is a place where linen is stored and where the maids' carts are kept. We must bear in mind that each maid will handle anywhere from 12 to 15 rooms and that each maid will need a cart. The number of rooms on the floor will, therefore, determine the number of maids and, in turn, the number of carts. Aside from the space for the maids' carts, there must be a porter's closet for cleaning supplies, vacuum cleaners, pails, etc. A closed storage area should be provided for the storage of linens. In addition to the maids', porters', and linen supplies, sufficient space should be left for the storage of room-service carts. These carts will be brought to this area by the waiters after the guests have finished their meals. They may have to remain on the floor for some time waiting for the service elevator or elevators. Obviously, the service elevators will open out to this service area, so that all this activity takes place out of the sight and hearing of the hotel guests. Some hotel operators still insist on providing toilet facilities for the help in this area. Most

hotels, however, go on the assumption that the maids and porters will, in the absence of the guest, be using the toilet facilities of the guest rooms while they are working in them.

Banqueting Facilities

Most hotels and motels include meeting and banquet facilities. The smaller hotels may provide only a number of meeting rooms which may also be used for luncheons and dinners. Larger hotels will have a more diversified arrangement for meetings, luncheons, dinners, and banquets. The largest hotels are usually designed with a full banqueting and convention facility. The extent of these facilities will be determined by the hotel operator who, in turn, will convey his requirements to the architect. It is wise for the architect to have a thorough knowledge of what the feeding and space requirements for these facilities are.

The normal meeting room requirements are rather simple. The rooms will vary in size to accommodate anywhere from 10 to as many as 100 people. In most instances, wherever it is feasible, the meeting rooms will be arranged in a straight line, so that the walls separating one room from the other can be made movable. Movable, separating walls make it possible to achieve a great flexibility in the size of the rooms to accommodate meetings of various sizes. Thus, if two meeting rooms which normally might seat 25 people are thrown open to one, we would have a meeting room to take 50 people; and if another wall is opened, we would be able to seat 75 people, and so on. The numbers used are not necessarily those that will be found in hotels, they are merely used for convenience, as an example. In larger rooms, which normally qualify for conventions or large banquets, it is also possible to subdivide the space by the use of movable walls to create smaller rooms when a large room is not required. A large space which might seat 1,000 people when all folding walls have been moved back can be cut up into anywhere from four to six spaces, allowing for meeting rooms that can accommodate 150 to 250 people. In many instances both arrangements will be found in a hotel, so that there are lines of meeting rooms of a smaller nature, all subdivisible, and a really large space that is also subdivisible.

Thus far we have spoken of these spaces as meeting rooms. Most of these spaces will also be used to serve meals. These meals may consist of small luncheons or dinners for 10 or 12 people and go on up to accommodate as many as 1,000 people seated at tables for dining. Of course, in the really large convention halls, it will not be unusual to seat 3,000 or more people in one large convention banquet hall. Realizing that food must be brought to all these rooms, their juxtaposition to serving kitchens is highly important in arranging the plan. For the most part, food should be brought directly from banquet kitchens to the banquet spaces. In subdividing these spaces, the subdivision must be so planned that each space is contiguous to the kitchen and has its own doors to enable waiters to come and go between the banquet spaces and the banquet kitchen. In some instances, this is not completely possible, and it is an accepted practice, where small meeting rooms cannot be placed contiguous to the actual banquet kitchen, to arrange to serve through the same corridors that will be used by people coming and going as diners in these smaller spaces.

If the architect, working with his client, the hotel operator, has come to the conclusion that the subdivision of these spaces by means of movable walls is what will be included in

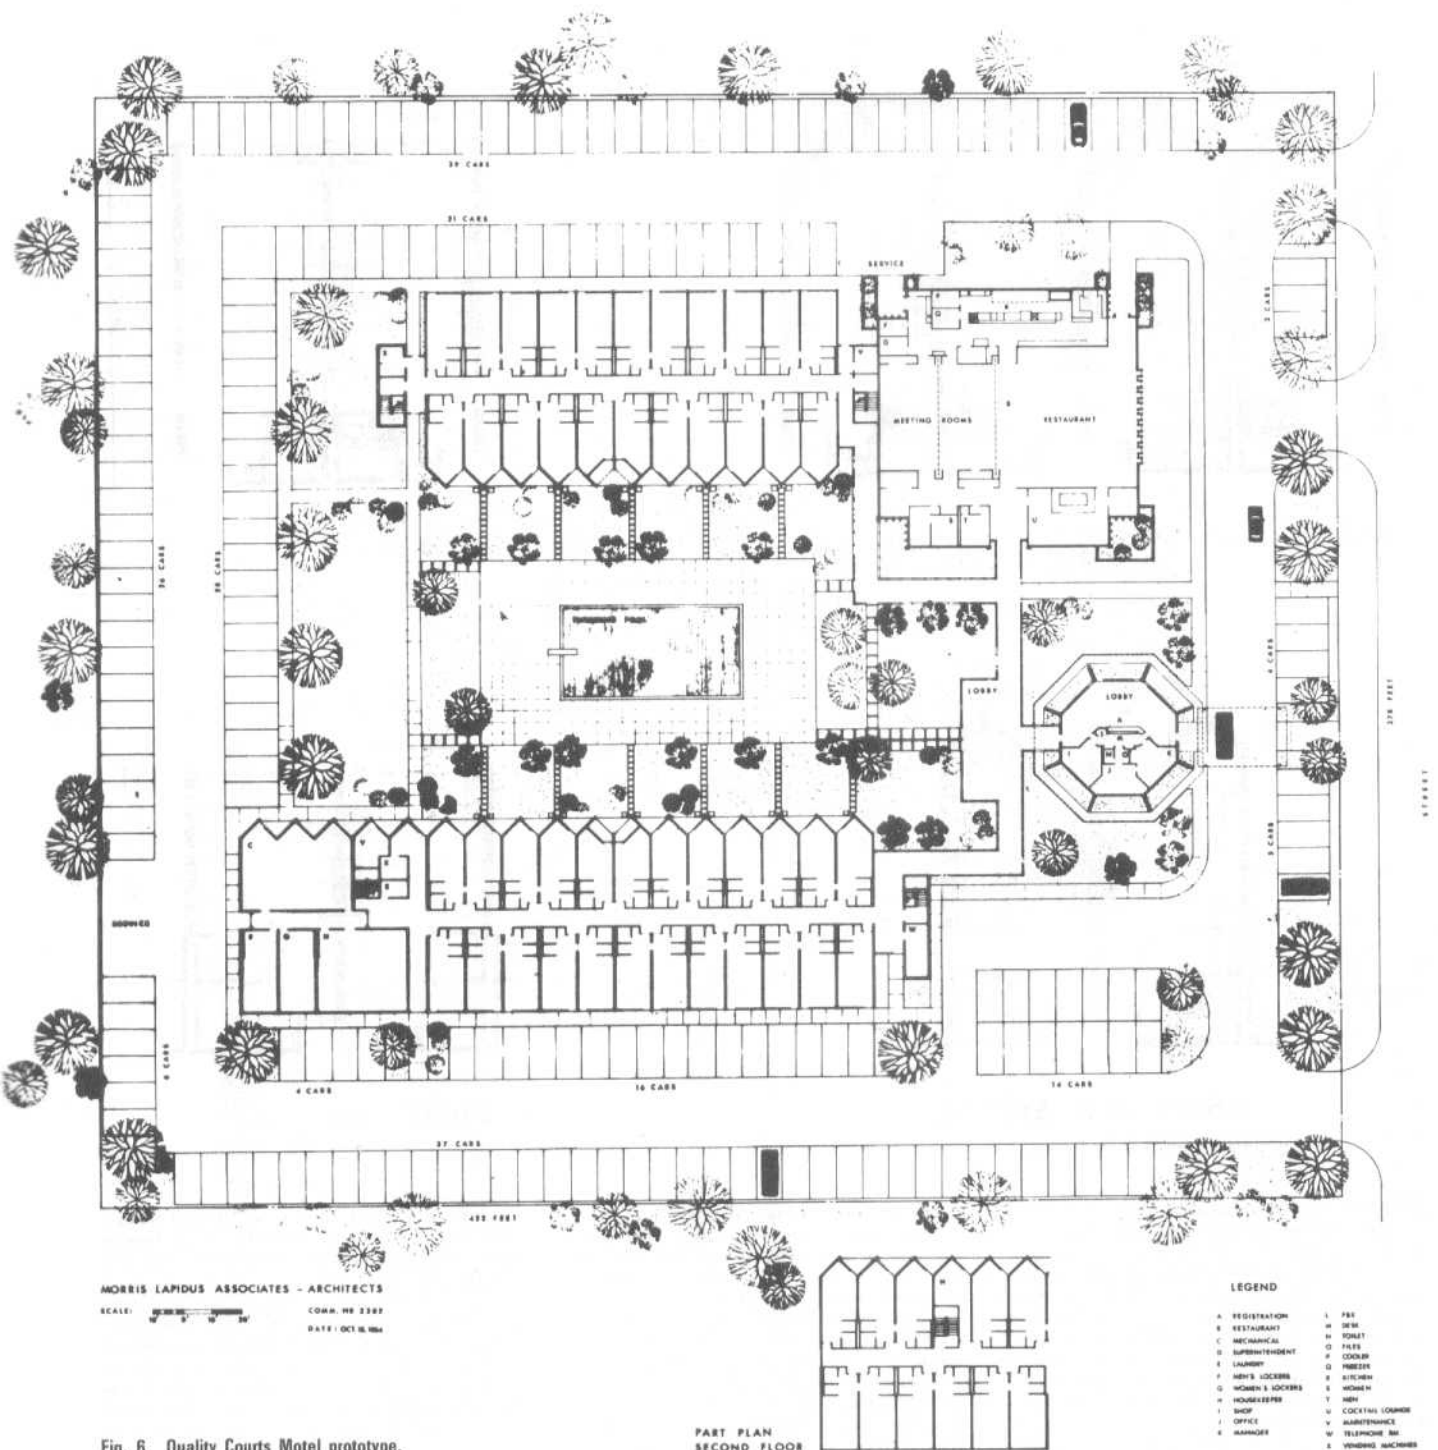

Fig. 6 Quality Courts Motel prototype.

the plans, it behooves the architect to make a careful study of the various types of movable walls available for use in such hotel facilities. There are many manufacturers who make these walls. The architect should be careful in arranging these walls so as not to interfere with the overall concept of opening up clear spaces by moving walls.

The acoustical value of the walls must be carefully studied. Nothing is more disturbing than to have two meetings in adjacent rooms where the sound transmission is of such a high

level that what happens in one space can be clearly heard in the other. Sound isolation is of the greatest importance, and this applies not only to the decibel rating of the panels themselves but also the arrangement of the joints between the sections or panels of the movable wall. The architect must also be aware of what happens above the panel as it comes up to the ceiling track and what happens to the panel as it glides along the floor. Sound isolation should be carefully studied in all these spaces, which will allow, if not properly controlled, sound to

be transmitted. There are practically no walls which can guarantee absolute sound isolation when the sound reaches a high enough decibel rating. In such instances, it has been found expedient to use two sets of walls with an air space between them, which will ensure almost total sound isolation. These movable walls or panels can be operated by hand or by motor. Sweet's catalog carries all the pertinent information from every manufacturer, and an architect is well advised to carefully study not only the operation and construction of these mov-

able wall panels but also the sound isolating devices that the manufacturer specifies.

In fairly large meeting, banquet, and convention facilities, space must be provided which is normally called "preconvention assembly space." Actually, this is a sort of foyer or gathering place for people before they go to the various meeting rooms or where they may congregate before going in to a banquet. Since most of the people who are standing are those who will eventually be seated, the proportions of the preconvention foyer space will be determined by the number of people who will be eventually seated. As a rule of thumb, a person standing in fairly close quarters will take up approximately 5 sq ft. A person seated at a table will take up anywhere from 10 to 15 sq ft. A person seated for a seminar or a meeting will require 8 or 9 sq ft. It thus becomes apparent that the ideal preconvention, prebanquet, or assembly space should be at least one-third of the area of the actual dining and meeting spaces. This one-third is arrived at empirically by comparing the amount of space required sitting or standing and by allowing for a diversity factor, knowing that not all the people who will eventually be seated will be

standing, since some of them will be late-comers and will arrive after many of the people have already gone in to be seated for their meetings or their meals. Even the one-third proportion may not be possible, and it has been found proper to use as little as 25 percent of the space for this preassembly foyer. It has been previously noted in this discussion of hotel and motel design that it is good policy to have a bar within this preconvention, premeeting space. Such bars do an excellent business. A fixed bar would be a very nice feature, but in many very large hotels it is normal practice to have movable bars set up. Very often there may be two or three bars to accommodate large groups of people.

MOTELS

Much of what has already been discussed will apply to motels. The term *motel* is rather loosely used. There are many so-called motels within cities which are, in fact, multilevel hotels providing more than the average parking found in a hotel. Where such a project occurs, it would normally be called a motor hotel.

Parking may be provided in an adjacent garage, in several levels below grade, or in several levels above grade with guests rooms starting on an upper floor above the garage levels. If property values permit, there may be an open parking area or a two- or three-story open parking garage. Whatever arrangement is eventually used, these structures should properly be called motor hotels rather than motels. Aside from the parking, everything that will be found in these motor hotels will be the same as what has been discussed under hotels.

A true motel is one which is normally found on a main highway, at an important intersection of several highways, or, finally, at a highway which enters a city and therefore is close to the city and yet not a part of it. The obvious reason is that land values within cities are too high to permit the spread that a true motel will require. Motels usually provide open parking and as a rule are only one, two, three, or at most four stories high. Usually most of the rooms will be entered from an open corridor, although this is not a hard and fast rule. There may be a combination of open corridors and closed corridors. The parking, by preference, should be placed as close as possible to the

actual room that the guest will be occupying. The great advantage that motels have is the ability of guests to park close to their rooms and to carry their luggage back and forth without the assistance of a bellboy. Bellboy service is available when required, but many guests arriving by car prefer to handle their own luggage. The option should be with the guest rather than with the management of the hotel.

In the highway motel the lounge and registration area as well as administration offices may be within the buildings housing the guest rooms, or they may be completely separate as an entity which is reached from the motel rooms by means of covered or enclosed passages. Housekeeping and maintenance spaces may be placed within the management and registration area, attached to the motel wings, or housed in a separate small building to handle laundry, housekeeping supplies, locker rooms for help, and maintenance shops and storage for taking care of the grounds, the swimming pool, etc.

The restaurant which will be a part of the normal motel complex may be attached to the management and registration area or, again, may be in a separate building or in a build-

ing attached to the motel wings rather than to the building housing management and registration. In many motels the food operation is a lease arrangement and is run by chains of food and beverage companies that make a specialty of operating restaurants for individual motels or for motel chains.

Quality Court Motels are used in this context as an example. (See Figs. 6 and 7.) Our office has prepared prototypes for this company for motels ranging in size from 51 rooms, 76 rooms, 103 rooms, on up to 150 rooms. In the case of this particular organization, where the motels are usually individually owned and operated under a franchise, the food operation is a lease operation, but in every respect each of the motels contain the same basic element: namely, the registration and administrative building and a restaurant varying in size depending upon the size of the motel. A standard feature of every motel is an adequate swimming pool and pool deck (an amenity which is invariably found in all highway motels), ample parking to take care of all the guest rooms, and sufficient parking for restaurant guests who may not be staying at the motel.

Motel guest rooms differ somewhat from hotel rooms. Motels cater to two distinct clienteles. One type is the traveling businessman using a car for transportation. He usually travels alone. All he wants is a small room for his overnight stay. The other guest accommodation is for a traveling family. Here a large room is wanted. It will have two king-size beds to accommodate the parents and two children. A careful study of the location will yield the clue that will determine the mix of small and large rooms. Drawer space is not a necessity; several shelves and luggage stands are of prime importance. Closets may be and usually are omitted. Most motels are designed for single overnight stays. The use of an additional lavatory is suggested. This amenity permits a family to complete its toilet rapidly for the usual early morning start. (See Figs. 8 and 9.)

A space should be provided for vending machines that dispense hot and cold drinks, candy, snacks, and magazines. An ice maker is a must, as well as insulated ice buckets for each room. Self-service of traveler comforts and needs by means of vending machines is an extra boon for the road-weary traveler who is anxious to get his night's rest.

Hotel Planning Consultant and Professor of Hotel Engineering, Cornell University

SPACE ALLOTMENTS

In designing hotels, architects are frequently handicapped by the lack of factual data on space requirements. Too much space results in excessive investment and building-maintenance costs. Too little space makes it difficult for the hotel owners to realize satisfactory profits and, in service areas, causes crowding, reduces speed, and increases payroll.

Information on a few hotels can probably be obtained by the architect. However, the data may apply to hotels of the wrong size, possibly of a different type, or designed to meet unusual requirements. Even with a set of complete plans, there is no assurance that the areas shown are the right size or that the building will be well suited to the complex business of hotel operation. Generally, the data collected from the sources usually available are incomplete, unrepresentative, or otherwise inadequate.

In order to obtain space-allotment figures that would be reasonably reliable, the plans of more than 40 hotels were examined. These ranged up to 500 guest rooms in size, were of wide geographic distribution, and all were built within the last 25 years. They were predominantly of the transient, commercial type and were believed to be representative. Although several were in resort communities, this had little influence on the space allotments for the working areas. Residential hotels and apartment houses were not included.

ORGANIZATION AND USE OF GRAPHS

In general, each space allotment is plotted on a separate graph, with the total number of guest rooms in the hotel as the base line, for this appears to be the most feasible common denominator. The plotted points (each representing one hotel) often pepper the graph in a widely scattered manner without suggesting a good location for a trend line running through the field of points. The plotted points for the lobby, main kitchen, and boiler room, however, indicate that the size of these areas varies directly with the number of guest rooms. This is a reasonable expectation for other areas.

To arrange the information in a clear and usable form, a solid diagonal line is started at "zero-zero" in the lower left corner of the graph and located by trial to show the median trend running up through the field of the points so that half the points are above the line and half below it. On most of the graphs, two broken diagonal lines are drawn in addi-

Explanation of graph

tion. The upper diagonal line is located by trial so that one-fourth of the total plotted points are above it, and the lower diagonal so that one-fourth of the points are below it. As a result, the fan-shaped area between the two broken diagonal lines contains 50 per cent of the points plotted and may be considered as the usual range of practice.

This method of presentation enables the designer to grasp at a glance the relative number of data points, their location, distribution, and trend. He may then determine what deviations from the median value are required for his hotel. The occasional points plotted above the range of the grid are not located to vertical scale.

The generalization that the usual space allotment for the front office is 1 sq ft per guest room is true. By glancing at the graph, however, the designer can estimate the reasonable tolerance above and below this value.

The space allotments for the 455-room Hartford Statler-Hilton Hotel are worthy of special designation and are indicated, where shown, by an X on the data point. The designers, already thoroughly versed in hotel planning and accustomed to attaining high standards of guest comfort and operating efficiency, spent several years of research in planning this structure. The data points that vary appreciably from the median values were for the most part the results of a reevaluation of hotel space requirements, and not due to circumstances peculiar to this hotel.

The method of presentation is such that one or two unusual instances have little influence on the trend line. In contrast, taking an average value might be influenced considerably by one or two abnormally high or low values.

This information is not presented as the final word on space allotments. But it should serve as a reliable guide in

Commercial HOTELS

future planning, subject to modifications to meet individual requirements.

GENERAL DATA

Certain general data warrant consideration to give an approximate over-all idea of the typical hotel with any given number of guest rooms.

Building height is indicated by the number of stories above ground. The results of a survey of 125 hotels are shown on the graph, plotted with logarithmic coordinates. The curve rises rapidly, showing the typical 200-room hotel to be 10 stories high, and then tends to level off, showing the typical hotel of 2,000 to 3,000 rooms to be about 25 stories high.

Ground-floor area is shown with the plotted points widely scattered on the graph. The available ground area and the number of guest rooms to be placed on it account for the wide dispersion. In general, the more guest rooms, the greater the ground-floor area. ("M" is the abbreviation for 1,000.)

Typical guest-floor area usually covers about 55 per cent of the ground-floor area, according to the data presented. The guest-floor area may vary greatly, however, depending upon individual circumstances.

Guest rooms per typical floor are shown with a wide dispersion of the plotted points. If there were a standard average-

size guest room and a standard percentage addition for corridors, stairways, and the like, then the points on this graph would follow a pattern similar to the graph for the typical guest-floor area, because the area for each data point would be divided by a constant value representing each guest room plus allowances. No such standards exist, however, and therefore the two patterns show no marked resemblance.

Usually each maid is assigned to about 16 rooms, which should all be on the same floor. If feasible, the number of guest rooms on the typical floor should be a multiple of 16 or quite close to it. On the graph, the horizontal bands indicate that one maid would handle from 14 to 18 rooms, two maids twice this number or from 28 to 36 rooms, and three maids three times the number or from 42 to 54 rooms. In more than half the hotels studied, the housekeeper apparently has some difficulty in arranging maid assignments.

Guest-floor stairways tend to increase in number with the number of guest rooms on the typical floor. Regulations limiting the distance from the guest-room door to the nearest stairway entrance usually require a minimum of two stairways on the typical floor. The graph shows that two stairways are usually enough if there are no more than 40 guest rooms per

floor. In general, there are about 15 to 20 rooms per stairway.

Elevators are provided according to the number of guest rooms. The number of elevators is of course also influenced by other factors such as the height of the building, the speed of the elevators, and the desired average frequency of service. The total number of guest and service elevators is presented on the graph.

A special study of elevators in 100 hotels showed the distribution between guest elevators and service cars (including short-lift cars) to be as follows:

Number of rooms in hotel	Guest cars per 100 rooms	Service cars per 100 rooms
50-150	1.3	1.0
150-550	0.7	0.5

Expressed another way, about 60 per cent of the elevators are guest cars and about 40 per cent are service cars.

The typical hotel has six main space divisions, classified according to function: (1) Public space, (2) Concession space, (3) Subrental space, (4) Food and beverage service space, (5) Guest-room space, and (6) General-service space. Each division will be considered separately. The percentage of the total area that is productive (revenue producing) space is of special significance. Preferably, at least 50 per cent of the total area should be productive space.

PUBLIC SPACE

Public space comprises those areas that are open to the public as necessary auxiliaries but that generally do not yield a direct profit. Typical inclusions in these areas promoting guest convenience are the lobby, lounge, public toilets, and entertainment rooms.

The lobby including front office is usually assigned about 11 sq ft per guest room. The tendency in recent years has been to reduce the size of this nonproductive area. Formerly, 14 sq ft was not uncommon, but now 9 sq ft is often considered ample. About 40 per cent of the points on the graph do not exceed 9 sq ft per guest room.

The front office is the nerve center or control point for many of the activities of the hotel. The front office, or front desk, has guest-contact stations for the registry, cashier, information, and mail. The average allotment is 1 sq ft per guest room. The specialist in front-office operation and equipment may recommend the dimensions desired for best results. A straight-line counter is generally preferred, with a length of 10 ft for a 50-room hotel, 15 ft for 100 rooms, 20 ft for 200 rooms, and 26 ft for 400 rooms.

The lounge is usually allotted about 6 sq ft per guest room. The graph shows, however, that half the hotels studied use

only 4 sq ft and a few even cut this area to 2 sq ft per guest room.

The lounge usually adjoins the lobby so that guests waiting in the lobby can overflow into the lounge. Some designers simply designate the area "Lobby-Lounge" with no demarcation between them.

Public corridors adjoining the lobby are often designed so that the lobby is set back from the street entrance and is reached by one or more corridors flanked by stores, restaurants, or other areas. This nonproductive area is justified if it permits a high return from street-frontage areas. Some layouts require no such corridors. The space allotment is dependent more on design than on the number of guest rooms.

The combined lobby, lounge, and adjoining corridors are quite flexible in the allotment of space. To bring these three nonproductive areas into proper perspective, the sum of the areas is given on the graph. The combined areas show a close correlation with the size of the hotel, with an average allotment of about 16 sq ft per guest room. Some hotels, however, have reduced this nonproductive area to 12 sq ft per guest room.

The men's toilet(s) for guests should be adequate in number, but not excessive. The required space may be divided into two widely separated rooms or simply provided in one location. The convenience of guests and of restaurant and bar patrons should

be the chief consideration in planning the location. This facility should not be too accessible to the man on the street.

The women's toilet(s) for guests should be provided on the same basis as the men's toilet facilities. In addition, the entrance should be inconspicuous.

The women's restroom(s) for guests frequently precedes the women's toilet. It is an appreciated convenience. The restroom is generally of about the same area as the adjoining women's toilet. The combined allotment for the women's toilet and restroom is typically 1 sq ft per guest room. Some recently planned hotels have cut this figure in half to reduce the nonproductive area.

Entertainment quarters and game rooms are properly classified as public space because they seldom yield an annual profit. Thus, if a ballroom were used only for dances and other entertainment, it would be included under public space. However, since a ballroom is also used for banquets, it is more suitably included under food and beverage service space and will therefore be considered later.

CONCESSION AND SUBRENTAL SPACES

Concession space is for guest-paid hotel services that might be run by the management or sublet on a percentage basis. It may well include a barber shop, beauty

Commercial HOTELS

parlor, cigar and news stand, and valet shop.

Subrental space is for services that are not normally provided under hotel operation, such as stores, permanent exhibits, travel agencies, offices, and club quarters. The rental is usually a fixed monthly amount.

These two income-producing divisions are treated together for the purpose of space allotments.

The barber shop is in considerably less demand than formerly. Less than half of the recently constructed hotels have this facility. If provided, the allotment is about 1.5 sq ft per guest room. Typically, the barber shop requires 90 sq ft per chair and a minimum of 4 chairs.

There were insufficient data on the beauty parlor to warrant a graph. The beauty parlor, if provided, usually has about half as many chairs as the barber shop in the same hotel. The required area, including space for manicure tables and lockers and toilet for employees, is about 200 sq ft per chair.

The cigar and news stand is customarily operated by the front desk in the smaller hotels. Medium-size hotels often place this area adjacent to the front desk so that it can be operated by a separate clerk during busy hours and by the front-office person-

nel during slack periods. In some hotels, this area is operated by the drugstore concession. The largest hotels may place the cigar and news stand across the lobby from the front desk.

The valet shop handles the pressing and cleaning of the guests' garments. Usually the service is provided for the guest through the bellman. The valet shop is generally located adjacent to the laundry in the larger hotels and is allotted about 1 sq ft per guest room. Many hotels, finding that guests expect this service, have had to improvise because it was not included in the plans. Sometimes the area has no pressing equipment but merely serves as the pick-up and delivery station for a local concern in the business.

A telegraph office, requiring 40 to 60 sq ft, may be desirable in the larger hotels to relieve the front desk of the work of processing guest telegrams.

The extremely high cost of land and the heavy tax assessment in the choice retail district of a city generally make it necessary to count on store rentals to carry the premium cost of the land, regardless of whether the owners prefer the inclusion of stores.

The number of rented stores, as indicated by the wide dispersion of the data

points on the graph, depends more upon circumstances than upon the number of guest rooms. The graph does not indicate the percentage of hotels without stores. If stores are included, however, there is generally about one store for every 35 guest rooms.

The total area of rented stores increases with the size of the hotel. Rented stores are well advised to have a direct entrance from the street; however, an additional entrance from the lobby increases the rental value. If stores are provided, 20 sq ft of store area per guest room is the average allotment. Some designers increase the income potential by raising this figure to 30 sq ft of store area per guest room.

Storage space for rented stores enhances the rental value of the store. Most hotels provide a separate area, often in the basement (where space is far less valuable), to serve as a receiving room, a place to open boxes and to store a moderate amount of merchandise. A comparison of the typical values shows that the storage space is frequently about one-fifth of the store area, and in some instances at least one-third of the store area.

Other subrental areas are sometimes provided for travel agencies, offices, and club quarters. No definite conclusions can

be drawn, however, because of fragmentary data on the scattered uses of these areas.

FOOD AND BEVERAGE SERVICE SPACE

This division includes all areas used for the receiving, storage, preparation, and service of food and beverages for guests, the general public, and employees. It includes the receiving area, storerooms for food and beverage supplies, china, glassware, and silver, and also the kitchen, restaurants, banquet hall, private dining rooms, employees' dining area, food service pantries, bar, cocktail lounge, and garbage room (sometimes with an incinerator).

The main dining room area should not be determined merely on the basis of average data. The probable demand for a main dining room should be estimated with care, for, at best, profitable operation is especially difficult. The difficulty is due to the necessity of long hours of operation at slack load together with competition from other restaurants. About 16 sq ft per seat is required for the dining room. The allotment varies from 18 sq ft for de-luxe dining rooms to 14 sq ft for popular priced places. The typical allotment of 16 sq ft of main dining-room area per guest room is not especially helpful in planning.

The main kitchen should be sized for the

work load. In addition to the main dining room, the main kitchen may also have to service the coffee shop, the banquet hall, private dining rooms, employees' meals, and room service to guests. Such conditions apply to the Hartford Statler, for example, where the kitchen is 33 per cent larger than the main dining room. If the kitchen is to service only the main dining room, however, its area is customarily 40 to 45 per cent of the dining room area. In two of the hotels studied the kitchen serviced only the coffee shop; in two other hotels, it serviced the coffee shop, private dining rooms, and, presumably, employee meals.

It was not feasible in analyzing and presenting the data to separate the kitchen work load into its several types of components and their sizes or the number of persons served.

A bake shop, of one type or another, is usually provided. In many of the smaller hotels, the baker occupies a corner of the kitchen. If a separate bake-shop area is provided, the typical allotment is 2 sq ft per guest room. However, it is preferable to size it for the work load. If a separate bake shop is provided, its area is usually equal to 20 per cent of the kitchen area.

The coffee shop provides quick food service at moderate prices. Of the 46 hotels analyzed, 63 per cent had a coffee shop.

About 7 sq ft per guest room is the usual allotment.

The area required per seat in coffee shops is about 18 sq ft per seat for counter service only, (this area includes the counter), 16 sq ft per seat for both counter and table service, and 14 sq ft per seat for table service only. Frequently about one-third of the seats are at the counter.

An auxiliary kitchen for the coffee shop is customarily provided if the coffee shop is remote from the main kitchen. Under these circumstances, the auxiliary kitchen may be "backed-up" by the main kitchen, which prepares such heavy-duty items as roast meats, or it may have complete facilities for cooking almost everything on its menu. The auxiliary kitchen is generally from 20 to 25 per cent of the area of the coffee shop. However, the extra kitchen payroll and equipment required make it desirable to plan so that an auxiliary kitchen is not needed.

The bar and cocktail lounge may be separated, adjoining, or combined. Sometimes one area is shown without the other. For each hotel analyzed, the data point shows the total area. No data point is shown for any of the several hotels that had neither bar nor cocktail lounge.

If the area is provided, 7.5 sq ft per guest room is the typical allotment. However, it is well to estimate the amount of

business that the bar and cocktail lounge will handle in view of the characteristics of the community and the type of patronage likely to be attracted. The space allotment should then be altered proportionately.

The number of private dining rooms indicated on the graph does not include instances in which the banquet hall is divided into smaller dining areas by folding walls or sliding partitions. Most hotels that serve food have private dining rooms, with an average of one room for 80 guest rooms. The use of private dining rooms depends more upon the demand in the particular community than upon the number of guest rooms.

The total area of private dining rooms is typically 7 sq ft per guest room, but variations are extremely wide. The seating capacity is often estimated at 10 or 11 sq ft per seat. However, much depends upon the right dimensions to accommodate the desired layout of tables, chairs, and aisle spaces, which have certain minimum sizes. If the room is large and its dimensions are right, 9 sq ft per seat is a possibility. Small rooms with random dimensions may require nearly twice as much area per seat.

The typical private dining room has an area of 600 sq ft, for the graphs show that 6 of them have a total of 3600 sq ft. If several private dining rooms are provided,

it is usual to have the sizes increased progressively to care for various size groups. For example, capacities of 15, 25, 40, and 70 seats would provide a good variety. There is a decided advantage in having private dining rooms adjoining and separated by folding, sound-absorbing partitions.

The banquet-ballroom was provided in half of the hotels studied. It is generally used more frequently for banquets than for dances. The probability of its operation being financially successful is often a serious question. If provided, the allotment is usually from 10 to 20 sq ft per guest room.

A banquet-ballroom foyer is recommended. The size is usually one-sixth to one-third of the banquet-ballroom area.

Banquet-ballroom storage, preferably adjoining the banquet hall, is required for chairs and tables. This storage area is typically about one-tenth of the size of the banquet hall, as may be determined from the two graphs.

The banquet-ballroom serving pantry is often simply a food-assembly and pick-up area. Pantry space is sometimes provided within the main kitchen if adjacent to the banquet hall. In other instances, a separate room is provided adjacent to the banquet hall, with plate warmers, hot-top serving tables, refrigerators, serving counters, coffee urns, and sometimes dishwashing facilities.

Occasionally, cooking equipment, such as broilers, is included and the area is then known as the banquet kitchen. Obviously, the requisite space allotment per 100 banquet seats varies with the function of the pantry. The typical ratio assigns to the pantry an area equal to 23 per cent of the banquet-hall area, but in a dozen separate investigations the ratio was from 12 to 38 per cent.

An employees' dining room is provided for the bellmen, maids, elevator operators, and the like. (Other employees such as the staff from the front office and the accounting department usually eat in the coffee shop.) Seats are usually provided for half of those on hand for the noon meal, since all do not eat at one time. Food service is often cafeteria style with a simple menu. The necessary space including the serving counter should be determined on the basis of 18 sq ft per seat and the number of employees to be seated at one time. If this is not feasible, the graph shows that 1.4 sq ft of employees' dining room is the typical allotment per guest room, a value that is generally satisfactory.

The steward's storeroom provides the storage space for dry foodstuffs, canned goods, vegetables, dairy products, and meat. Platforms, shelves, refrigerators, and freezers are needed. Deliveries are usually made at least three times a week, although

the service is less frequent in larger storage facilities. Typically, 4 sq ft is allowed per guest room for hotels having the average ratio of food and beverage sales to room sales.

Beverage storeroom(s) should be provided separately from general food storerooms in order to ensure adequate control. Sometimes beverage storage space is provided in the steward's storeroom, generally in a fenced-off area. Wine and liquor are of such value as to definitely warrant separate storage under lock and key. Beer and soft drinks are desirably, but not necessarily, stored in separate rooms. The areas on the plans studied are not always marked specifically; the designation may be beverage storage, or wine and liquor storage, or four separate rooms for wine, liquor, beer, and soft drinks. Whatever the designation on the plans, this area was considered as the beverage storage space in the analysis.

The typical allotment is 1.4 sq ft of beverage storage area per guest room, although often this figure was only for wine and liquor. Probably 2 sq ft of total beverage storage should normally be allotted per guest room.

The receiving room is provided for food, beverages, linen, and other supplies which, upon arrival, are customarily checked against delivery slips, weighed, counted, and inspected. These supplies remain in

the receiving room until time and manpower are available to take them to appropriate stock rooms. The typical allotment for the receiving room is 1.6 sq ft per guest room, although the graph shows wide variations.

A garbage room is required for quantities of garbage, bottles, cans, and cartons, which accumulate between daily removals or longer intervals over the weekends. Such refuse should not clutter the receiving room or be placed outside the back door. Health authorities object to garbage cans being kept in the kitchen.

Nearly half of the plans studied in the basic survey had no area designated as the garbage room. Plans of additional hotels were consequently studied to give more data points on the graph. The typical allotment for the garbage room of 0.75 sq ft per guest room is generally satisfactory. The use of garbage- and trash-disposal equipment will also influence the size of the room.

GUEST-ROOM SPACE

This division includes the guest rooms together with guest bathrooms, clothes closets, and entrance vestibules, the sum of which is the area that the guest rents. Also included are the necessary auxiliary areas found on the typical floor, such as guest corridors, stair wells, elevator shafts, and

maid's closets. Any parlors (usually part of a suite) are included. If provided, sample rooms for the display of merchandise are also considered guest-room space, regardless of their location.

A schedule is customarily prepared stating the approximate total number of guest rooms. This is subdivided to give the number and approximate size of each type of room desired, such as single, double, and twin beds, and any sample rooms. Decision must be reached on what proportion of the rooms of each type is to be of the conventional and of the studio styles. King-length beds versus those of standard length must also be considered. Unless stated otherwise, each guest room has a three-fixture bath and a clothes closet.

These problems of guest-room space must not be considered trivial; indeed, the main reason for building a hotel is to rent guest rooms, which are the unquestioned source of greatest profits. Every mistake, every omission, and every point of excellence is multiplied by the number of rooms constructed. Extremely careful planning is warranted for it pays big dividends.

GENERAL SERVICE SPACE

This division, classed as nonproductive space, includes those areas for general administration, operation, maintenance, and storage that are not otherwise classified.

Commercial HOTELS

They include executive and administrative offices; areas devoted to the handling and storage of linen; help's quarters; maintenance shops; rooms for housing the mechanical equipment for heat, light, power, ventilation, and refrigeration; and also certain storerooms. Areas related to food and beverage are not included because they have been classified separately.

The manager's office requires a minimum area of about 100 sq ft. (Note that the trend lines on the graph are not drawn through the "zero-zero" point.) This area may well increase slightly with the size of the hotel, but the activities in this office seldom justify more than 200 sq ft. About 140 sq ft is the most common space allotment, regardless of the size of the hotel.

The accounting office should have a minimum area of about 100 sq ft to accommodate one person at a desk with appropriate record-keeping and filing equipment. (On this graph also, the trend lines are not drawn through the "zero-zero" point.) As the size of the hotel increases, more accounting personnel are needed requiring more space. The typical area of the accounting office for a 200-room hotel is shown on the graph as 200 sq ft, whereas for a 400-room hotel it is 300 sq ft.

Quite often the plans do not provide for the accounting office. Since the hotel operator cannot get along without this facility, he is generally forced to adapt one or two

guest rooms (along with bathroom, clothes closet, and vestibule) for the purpose. The investment in the bathroom area and plumbing equipment is lost, the potential profit of five dollars per day on the room is wiped out, and the location of the improvised accounting office is often inconvenient. If an effort to economize caused the accounting office to be omitted from the plans, it was certainly misdirected and proved to be very costly.

A linen room is necessary to accommodate the housekeeper's office and the shelves of neatly stacked linens, together with the counter over which the maids receive their supplies. Often the lost-and-found cabinets for articles left in guest rooms are located here. Frequently a sewing machine and mending table are provided. Various employee uniforms are stocked and distributed here. The space allotment for the main linen room is usually from 2 to 4.5 sq ft per guest room, according to the graph, with many hotels favoring the larger value.

A laundry is sometimes operated by the hotel, although frequently the hotel laundry services only flat work and uniforms, and sends out guest laundry. To determine whether the hotel should operate its laundry requires an analysis of the costs of complete linen service, costs of commercial laundering, local wage rates, relative life of linen, availability and costs of space,

necessary linen inventory, responsibility of running another department, and other factors. In general, the larger the hotel, the more likely it is to run its own laundry. (For a more detailed discussion of this subject, see section on Hotel and Motel Laundries.)

The graph shows that if a laundry is installed, it is usually allotted 7 sq ft per guest room. In a few cases, the allotment is only 4 sq ft per guest room.

The men's toilet and locker room in the employees' quarters is generally allotted 2.4 sq ft per guest room. Thoughtful planning justifies at least half again as much space, or 3.6 sq ft per guest room. The Hartford Statler with 455 guest rooms allotted 2,550 sq ft, with the ratio being 5.6 sq ft per guest room. There is reason to believe that the average figure results in crowded and unsatisfactory conditions.

Two separate but adjoining rooms are generally but not always provided. In general, about 35 per cent of the area is allotted for the toilet facilities and 65 per cent for the locker room. The requisite number of toilet fixtures for the size of the staff is the logical but more detailed way to arrive at the solution.

The women's toilet and locker room is usually allotted about the same space as the men's, and should be increased by the same amount.

In providing equal space for men and

women, we of course assume that they will be employed in approximately equal numbers. If the operating policy favors waiters instead of waitresses, then the space allotment should be adjusted accordingly.

Maintenance shops are necessary to keep the hotel running. There should generally be a minimum of three separate rooms: (1) Plumbing-and-electric shop, (2) Carpentry-and-upholstering shop, and (3) Paint-and-varnish room. The work in each shop is such that it does not mix well with the others. The plumbing shop is sometimes in the boiler room although not marked on the plans. The typical allotment for maintenance shops is 4 sq ft per guest room.

Some hotels have cut this allotment in half. General maintenance suffers as a result. When the means for repair are lacking, things that could be fixed have to be replaced by buying new ones. The reduction in initial cost is more than offset by increased operating expense.

Furniture storage is required for extra items of furniture and broken pieces awaiting repair. They should not be placed in basement corridors. The typical allotment for furniture storage is 2.5 sq ft per guest room, apparently a reasonable and satisfactory amount.

The boiler room space allotment is determined by many factors, such as the climate, the various uses of steam, the type of boilers, and the capacity of the standby boiler. Water heaters for the usual hot water supply are often placed in the boiler room although not noted specifically on the plans.

The graph shows the angle between the two broken lines to be relatively narrow. The middle 50 per cent of the points do not "fan out" over a wide angle. Consequently, the typical allotment for the boiler room of 6 sq ft per guest room may be used as a preliminary figure subject to possible revision after details have been developed.

Fuel storage is not required if gas or district steam is used exclusively. If coal or oil is the only fuel or reserve fuel used, however, then storage space is needed. The amount of storage, of course, depends on such factors as maximum rate of use, frequency of delivery, and cost of providing storage space. It is not surprising that some of the data points are far from the average line. The typical value for fuel storage is about 2.2 sq ft per guest room. This value may well be revised to suit the specific conditions that apply.

A transformer vault is a necessary part of the hotel's electrical system. The electric energy used goes through a bank of transformers, which are sometimes located out-

side the hotel but more frequently in the basement in a specially constructed vault. An allotment for the transformer vault of 1 sq ft per guest room is usually adequate. If very extensive use of electricity is planned, the allowance should be checked with the electric service company as a precautionary measure.

PRELIMINARY SCHEDULE OF SPACE ALLOTMENTS AND FLOOR ASSIGNMENTS

The following example of applying the statistics to a proposed typical commercial hotel of 100 rooms is presented as a guide. First the general data indicate the over-all characteristics of the hotel. These data are followed by more specific space allotments, which adhere closely to the typical values shown on the graphs. Items marked with an asterisk have been added to furnish desired areas for which no graph was given;

items designated by a question mark may be omitted if the size of the hotel or other considerations do not warrant the area. In addition, the floor assignments are designated as follows: basement (B), ground floor (G), and typical guest floor (T).

Since many of the hotels in this survey were planned without certain desired areas,

SPACE ALLOTMENTS AND FLOOR ASSIGNMENTS FOR TYPICAL HOTEL OF 100 ROOMS

General data and approximations

Height of building above ground (ground floor plus 6 typical guest floors)	7 stories
Ground-floor area	10,000 sq ft
Typical guest-floor area	6,000 sq ft
Guest rooms per typical floor,	17 rooms
Stairways on the typical floor,	2 stairways
Elevators (1 guest and 1 service car)	2 elevators

The first four factors listed above are of course all interrelated and must be organized as a compatible group.

	Productive area, sq ft	Nonproductive area, sq ft
Public space		
Lobby and front office		1,100(G)
Lounge		600(G)
Corridors adjoining (total of above, 1,900 sq ft)		200(G)
Men's toilet for guests		150(G)
Women's toilet for guests		100(G)
Women's restroom for guests		100(G)
*Coat checkroom		120(G)
*Bellman's checkroom		40(G)

Commercial HOTELS

	Productive area, sq ft	Nonproductive area, sq ft
Concession space		
Barber shop	180(B)	
*Valet shop	100(B)	
Subrental space		
3 rented stores, (each 800 sq ft)	2,400(G)	
3 storage rooms (each 200 sq ft)	600(B)	
Food and beverage service space		
Main dining room (90 seats)	1,500(G)	
Main kitchen		1,100(G)
Bake shop		200(G)
?Coffee shop (50 seats)	800(G)	
Bar and cocktail lounge	750(G)	
Private dining rooms (250 + 500 sq ft)	750(G)	
?Banquet-ballroom	1,400(B)	
?Banquet-ballroom foyer		450(B)
?Banquet-ballroom storage		140(B)
?Banquet serving pantry		350(B)
Employees' dining room		220(B)
Steward's storeroom		400(G)
Beverage storerooms		180(B)
*China, glass, and silver storage		300(B)
Receiving room		180(G)
Garbage room		80(G)
	Productive area sq ft	Nonproductive area sq ft
Guest-room space		
102 rooms (each 250 sq ft; including bath, closet and vestibule)	25,500(T)	
Auxiliary space (add 40 per cent of above for corridors, stairs, elevators, maid's closets, walls, and partitions)		10,200(T)
General service space		
Manager's office		140(G)
*Secretary's office		100(G)
Accounting office		150(G)
?*Sales and reservations office		140(G)
*Mimeograph room		40(G)
Linen room		350(B)
?Laundry (700 sq ft; omitted)		
Men's toilet and locker room		360(B)
Women's toilet and locker room		360(B)
Maintenance shops		400(B)
Furniture storage		250(B)
*Records storeroom		250(B)
*General storeroom		200(B)
Boiler room		600(B)
*Water-heater tank space		150(B)
Fuel storage		200(B)
Transformer vault		100(B)
*Refrigeration compressor room		400(B)
*Fan rooms, ventilation equipment		400(B)
Total productive area	33,980 sq ft	
Listed nonproductive area		20,800 sq ft
Add for basement corridors, walls, stairways, and elevators		2,500 sq ft
Add for ground-floor stairways and elevators		500 sq ft
Total nonproductive area		23,800 sq ft
Grand total of areas	57,780 sq ft	

it is well to make a liberal estimate of the total ground-floor area.

The above schedule shows a preliminary estimate of 59 per cent productive area and 41 per cent nonproductive area, which is a more favorable ratio than is generally realized in practice.

During the preliminary planning stage, it may be decided to allocate the 1,500 sq ft area to the coffee shop, thus eliminating the main dining room and reducing the size of the main kitchen by about 250 sq ft. The banquet-ballroom, together with its three auxiliary rooms, might be omitted or, if demand for these facilities is assured, placed in the basement. The laundry would probably be omitted, although it was placed in the schedule as a possibility.

From the standpoint of efficiency, it might be convenient to have almost all areas on the ground floor. However, to make the ground-floor and basement area approximately equal, those areas designated (B) have been consigned to the basement.

Thus the area of the ground floor including 500 sq ft for stairways and elevators, but omitting the 800 sq ft coffee shop and deducting 250 sq ft from the main kitchen, amounts to 10,590 sq ft. This figure compares satisfactorily with the preliminary over-all estimate of 10,000 sq ft for the ground floor.

The area of the basement including the banquet-ballroom facilities, but omitting the laundry, and allowing 2,500 sq ft for corridors and the like, amounts to 10,440 sq ft. This figure is about the same as the ground-floor area.

The typical floor has 17 guest rooms. Two stairways, the elevator shaft, and maid's closet increase the floor area by an equivalent of 3 guest rooms, making a total area equivalent to 20 rooms per floor. Ten rooms on each side of the corridor and each room with an assumed average frontage of 12 ft gives 120 ft as the approximate length of the typical guest floor. The width is usually about 50 ft. Thus the area of the typical guest floor (120 ft by 50 ft) is 6,000 sq ft, which checks with the estimate previously made under "general data."

The summary of areas is as follows:

6 typical guest floors, each 6,000 sq ft	36,000 sq ft
Ground floor, figured at 10,590 sq ft	10,500 sq ft
Basement, figured at 10,440 sq ft	10,500 sq ft
Total approximate floor area	57,000 sq ft

By FRANK HARRISON RANDOLPH, P.E.

Hotel Planning Consultant and Professor of Hotel Engineering, Cornell University

A motel can be defined as any type of sleeping accommodation designed and operated especially for the traveler who travels by car. It may be the most primitive structure, or a virtual palace. It may be called a cabin, a court, a lodge, an inn—or simply a motel.

Growth of the motel business

Since their crude beginning in the 1920's, motels have had a phenomenal growth, paralleling that of the automobile and the highway. Long characterized by small units located on the open highway, motels are now growing larger and moving into the fringes—and even the downtown areas—of large cities. The average size, which was only 15 rooms in 1952, had by 1959 increased to 35 rooms; motels with 100 or more rooms are not uncommon since large corporations have entered the field. Motels are now considered part of the hotel business. Many of the larger motels provide the same services as hotels, and it has become increasingly difficult to draw a sharp line of demarcation between them.

Essentials for success

The success of every motel is influenced by three factors, all of immediate concern to the designer: (1) Good location, (2) Attractive appearance, and (3) Quick, pleasant, and economical service.

TYPE OF PATRONAGE

There are two main types of motel patronage: transient and terminal. The transient motorist, whether traveling on business or for pleasure, generally has certain predictable preferences. Primarily, he wants ready access to his car and quick service. The terminal guest (who may have been a transient yesterday at another motel) has different preferences because he has reached his destination. He wants pleasing surroundings and recreational facilities.

Some motels are designed primarily for transients; others cater only to the terminal guest. Still others must be planned for both types.

Commercial hotels normally derive at least 85 per cent of their room sales from persons traveling on business. The city motel, in the absence of conflicting data, should expect about the same. As a typical example, a 40-room motor court, although 2 miles from the center of a good-sized city, found that business men supplied 85 per cent of its annual business.

And it was a popular motel—its average of 80 per cent room occupancy for the year was nearly 10 per cent above the national average.

Business travel is much greater in volume than vacation or pleasure travel. The volume of business travel is, moreover, fairly constant throughout the year: only 25 per cent more business travel takes place in summer and fall than in winter and spring.

Vacation travel, however, is two to three times greater in summer than in winter. This extreme fluctuation in the volume of business makes it extremely difficult to operate profitably a motel catering solely to vacationers. Most motels of over 50 rooms need almost 50 per cent occupancy to break even. Thus some motels find it necessary to shut down during the off-season to reduce the loss. Real estate taxes and building depreciation, of course, continue nevertheless.

Vacation trips are taken by over 75 per cent of our adult population, but about 60 per cent of these people do not always go to the same place. The most popular vacation destinations in the United States are Florida, California, New York, and Michigan (in that order). Roughly two-thirds of all vacation travel takes place during the summer, and the average vacation travel period is two weeks.

There is a definite need for more acceptable motels for people in the middle- and low-income groups. A new motel should guard against pricing itself out of the market. The designer should be especially careful that construction costs do not result in prohibitively high rental rates.

FEASIBILITY

Determining the probability of financial success for a project is recommended as the first step in planning. A dependable business forecast, based on local controlling conditions, should be made by a competent concern. This forecast should determine whether there is adequate need for a new motel and should give a general indication of the number of guest rooms and the type and extent of services to be provided. The forecast should be followed by selection of the site, working out of the financial plan, and finally, determination of the functional scheme: the number, types, and sizes of guest rooms, public spaces, and food and beverage facilities, the type of building construction, and the extent of mechanical services. Only after these preliminary steps have been completed is the

project ready to be started on the drawing boards. Otherwise, much time, money, and effort may be lost in developing specific ideas that are impractical and yet difficult to discard.

Basic economic survey

Many factors will require careful study by a qualified financial advisor, such as a firm experienced in hotel and motel accounting. Ever-increasing costs of construction and operation are vital considerations. The rapidly expanding and shifting pattern of major highways should be evaluated for its effect on the site. The possibility of an overabundance of motels in the area must not be overlooked. The soundness of the title to the land may be questionable. The decision of whether to purchase the land, build on leased land, or select a sale-and-lease-back arrangement may well have a considerable effect on taxes.

It will aid greatly in planning to have in advance an idea of the type of traveler expected, the probable length of his stay, and the seasonal fluctuations expected in the volume of business. Such a survey is unquestionably a help in determining the financial feasibility of a project. Seasonal variations may require a break-even point at close to 50 per cent occupancy.

Horwath & Horwath, Hotel Accountants and Consultants, stress the importance of determining (1) the rate of economic growth of the area, (2) the probable future development of the community, and (3) the status of existing or contemplated transient housing and feeding accommodations.

LOCATION

Site location is of paramount importance. Geographically, it should be at the end of a day's run for the motorist in order to attract transient business. The average motorist is not interested in stopping for the night except at the end of his day's run, so the site should be a day's run (or a multiple of this) from one or more reservoirs of potential transient business. The typical motorist covers about 300 miles in a day, plus or minus up to 100 miles, depending upon personal preferences and highway conditions, which need individual analysis for a given area. Obviously the motorist will travel considerably farther in a day on limited-access express highways than on the usual improved routes.

Traffic surveys showing the daily volume are of value only if they indicate the number of potential customers passing the site

during the critical few hours at the end of the day. The total 24-hour volume of trucks, local passenger traffic, and whatever else comes along means very little. A tally of all passenger-car license plates that passed in each direction during the end-of-the-day period, disregarding, if possible, those issued within a radius of about 200 miles, would give the most helpful indication of potential business for the day or days on which the count was taken. It would give no guarantee of volume, however, for another season or for future years.

Major highway routes are constantly changing, both in pattern and in condition. An excellent location today can become almost worthless next year because a new highway has bypassed it, taking virtually all of its long-distance passenger traffic. Or the condition of a long major route might be so greatly improved that, although the motel was formerly a normal day's drive from a potential reservoir of transient business, it would now be reached by most potential customers by midafternoon—at least two hours before their stopping time. Future highway conditions are difficult to forecast, since highway plans are often changed for unpredictable reasons with disastrous consequences for the motel, which may become virtually stranded. Careful checking with all the various planning agencies, especially the State highway department, is a precaution that must not be overlooked. Indeed, selection of the proper site requires the combined judgment of persons in many fields. The State highway department can forecast traffic characteristics. The chamber of commerce is familiar with recent civic development and building and population trends. The real estate broker knows land values. The construction engineer can report on soil conditions, excavation, and drainage, and indicate probable difficulties in building. The architect experienced in motel design will have a wealth of practical advice. The accounting firm that made the economic survey should be satisfied that the site is properly qualified. The finance company or bank that is to loan the necessary funds must be convinced of the apparent soundness of the venture. If a particular site is vetoed by any one of these qualified parties, the success of the enterprise must be considered open to serious question. There is no satisfactory substitute for an excellent location that meets these various criteria.

When the typical motorist, thinking he has travelled long enough for the day, realizes there is some difficult driving a short distance ahead, and then encounters an attractive motel, he will be nicely conditioned to decide to stop for the night. The

difficulty may be the heavy traffic of a large city, a winding road over a mountain, or a tedious long stretch of road through barren country—something he would rather postpone until morning. Situating the motel suitably in advance of such an obstacle can be definitely rewarding (Fig. 1).

Some motels successfully intercept the traveler just outside a city where he had thought to find lodging (Fig. 2). If several motels are already grouped along the highway leading into a city, a new motel can be expected to be more successful if it joins the group than if it selects an isolated location. Prospective guests tend to be favorably impressed by a large group of motels, which by its very magnitude suggests abundant hospitality and a popular motel area. Once he stops, the traveler is almost certain to stay at one or another of these places (Fig. 3).

If possible, the motel should be on the right-hand side of the road, especially if traffic is at all heavy, since drivers would rather not make a left turn (Fig. 4). If the highway curves, place the motel on the right of a left-hand curve, so that it will be directly in line with the driver's vision (Fig. 5). If the site selected slopes upward from the highway, the hillside location of the motel will add to its prominence (Fig. 6).

The best motel site is the one with the greatest appeal to the largest number of potential customers. The site should of course be plainly visible from a distance. Highway intersections are often excellent places for motels. Approaching motorists will already have reduced speed and be prepared to stop, and can readily size up the situation before reaching the intersection. The order of preference of several possible site locations at an intersection may be influenced by such factors as the slope of the land and the presence of existing or future buildings (Fig. 7, 8, 9).

If travel is about equal in both directions, the motel should aim for those who are going rather than those returning, because of the opportunity for repeat business. Twenty-five per cent of the guests of some motels are repeat customers.

If a town is bypassed by the main traffic route, the motel may be placed on the right-hand side of the road leading to the town, but should be plainly visible from the main highway (Fig. 10). If two towns are not far apart on the highway, the motel should be placed to intercept the major volume of traffic before it reaches either of them. Putting the motel between the towns generally proves unsatisfactory, since most motorists would not be in the mood for stopping on such an in-between stretch (Fig. 11).

It is important to determine well in advance whether the highway department will permit the desired location. Encroachments, set-back regulations, deceleration lanes, and access drives must all be considered. The highway department may not permit direct access from deceleration or acceleration lanes. Definite approval of specific plans should be obtained from the authorities at a very early stage in the planning.

Advance signs advertising the motel and directing the motorist are essential. Often the authorities have very severe restrictions on the placement of such signs; therefore, sign locations must be assured and permissions obtained before the site may be said to be satisfactory.

TYPE OF MOTEL

Motels can be differentiated by their location and purpose. The most common types are as follows:

1. The *city motel* is built in town or on the edge of town. It is intended primarily for commercial travelers with business in the downtown area. It generally involves expensive land, a restricted site, and a structure at least three stories high. Nearly the entire site is used for buildings and parking.

2. The *motor annex*, a relatively new development, adjoins an existing hotel in the city. Whether the motel emphasizes its connection as an annex will depend on the reputation of the hotel and its advertising, location, services, utilities, supervision, and maintenance staff.

3. The *highway motor hotel* furnishes roomside parking for the traveler en route. This type of motel is usually one or two stories high, with a site of at least three acres. If space permits, not more than 15 per cent of the site area is used for buildings and parking.

4. The *resort motel* is intended primarily for guests who have reached their destination, and usually requires ample facilities for recreation. Closing during the off-season may also be necessary. The site, ideally spacious, can be small if necessary.

5. The *airport inn* is built at a major, usually intercontinental, airport. A relatively large and high-class operation, this type of motel often has 150 to 300 rooms, two-story guest-room buildings, and a site of at least 10 acres. Business is supplied by airline patrons, motorists, and guests from the metropolitan area served by the airport. The size of such a motel permits full-scale food and beverage facilities, function rooms, and often as extensive recreational facilities as are found in resort motels. The location usually borders on the outlying in-

dustrial area, within easy driving distance of both the suburban residential area and the city.

SITE PLAN

Pertinent factors include the size of the buildings, the area for parking, size of the site, contour of the land, and the extremely important traffic patterns for guests, employees, supplies, and refuse. The ideal arrangement should combine "pull" with privacy—two items that are difficult to attain simultaneously in any site plan. The "pull" or drawing power of an attractive appearance from the highway should be converted to privacy for the guest after arrival. Drawing power is linked with proximity to the highway; privacy is associated with quiet surroundings. Some compromise must be made on the basis of the variety of motel, the type of guest, and the site conditions. One operator may want the motel set far back from the highway; another may want the swimming pool right out in front. The designer must know the preferences of the motel owner and operator in order to produce the results desired.

If the motel is to be located on a high-speed thoroughfare, it should have a frontage of at least 500 ft. The motorist going 60 miles an hour will need about that distance to slow down comfortably in order to turn off the highway.

For a small installation, the guest units may be arranged in a U-shaped pattern, with a lawn area in the center and the guest registration building at the middle of the horizontal portion of the U (Fig. 12). The same arrangement can be modified to provide unbroken construction, with everything under one roof (Fig. 13).

A crescent-shaped arrangement is often quite appealing. The central registration building may be flanked by guest units (Fig. 14). If built as a simple structure, this arrangement usually takes the shape of a half-hexagon (Fig. 15). Or the motel might be designed as a long, straight building, with equal wings extending from the registration office (Fig. 16).

For some sites, a T-shaped structure might be most suitable. With that design, however, the service entrance can be difficult to locate (Fig. 17). The L-shaped layout is deservedly popular. Placing the registration office toward the highway extends an obvious welcome to the motorist. The sight of other cars in the parking area will also be an inducement to the prospective guest. In addition, the garden and pool area will be secluded, so that the guest can escape the noise and confusion of the highway (Fig. 18). Or the position of the L might be reversed, and the ground

areas adjoining the building attractively arranged. The swimming pool, for example, could be placed out in front as an inducement to the traveler (Fig. 19).

If the site is approximately square, and located near or in town, the registration office may best be placed at the tip of one side of a U. This familiar solution is both well-ordered and attractive (Fig. 20). If the site is longer and has access to a rear street parallel to the highway, the U may advantageously be broken by a driveway connecting the streets. The driveway could then be covered at the registration office and access to the parking areas so arranged that control could be exercised by the office over all arrivals and departures (Fig. 21).

A relatively long, narrow site on the edge of town might be developed advantageously by setting the building back from the highway and providing good visibility, roomside parking, and efficient traffic patterns (Fig. 22). If the site were somewhat deeper, the building might be designed as a half-hexagon, with a garden court and recreation area. Whether guests would prefer roomside parking or an adjacent garden court and recreation area depends on such circumstances as the purpose of their visit, length of stay, climatic conditions, and the view from windows not facing the court (Fig. 23).

A large motel in the downtown area may take the form of a hollow rectangle. The example shown in Fig. 24 provides a wide scope of services, including a restaurant, ballroom, shops, room service, year-round swimming pool, and an attractive central garden area. Street-level parking is provided under the guest rooms. A similar pattern is followed in the 68-unit motel shown in Fig. 25. The registration office, gift shop, coffee shop, cocktail lounge, and restaurant are located in the portions of the building nearest the highway. The inner court provides parking space around an island lawn with trees. This arrangement permits good control of cars entering and leaving, brings the cars near the guest rooms, and may thus seem the obvious solution to parking problems. The noise of cars arriving and departing, however, often late at night or early in the morning, will affect all guest rooms facing the court, where the noise is accentuated by reverberation. Also, the headlights of arriving cars will rake the windows facing the court. In northern climates, snow removal can be a difficult problem as well, with the hollow-rectangle arrangement.

The 150-room airport motel shown in Fig. 26 uses the inside of the enclosure for the garden, recreation, and swimming-pool area, with parking facilities around the outside. Business comes from both airline

and motor travelers. Service is comparable to that of large hotels in the city. The circular building contains a dining room and cocktail lounge on the ground floor, and a second floor meeting room.

Individuality is an asset to the motel illustrated in Fig. 27. On a site of moderate area, this motel has a convenient, covered entrance for the motorist and an adjoining circular restaurant building, backed up by an L-shaped, two-story guest section. The outside dining terrace overlooking the lawn and pool is especially inviting with its open, yet secluded atmosphere. Separate parking areas are provided for restaurant patrons and for guests.

A motel may be built on a narrow strip of valuable land between the highway and the ocean, as is frequently done in Florida. The example in Fig. 28 concentrates the three stories of guest rooms (with a double-loaded corridor) perpendicular to the shore line, providing an ocean view from every room. All guest rooms have private balconies. A garage in the semibasement accommodates self-service parking. The single-story lobby, bar, and coffee-shop portion includes a dining terrace that overlooks the circular outdoor dance floor, the pool, and the ocean. The arrangement is open, uncluttered, and inviting.

ROOM GROUPS AND PARKING

Designed for the convenience of the motorist, each room of the motel should have, if possible, at least one window with a desirable view or private outlook on a quiet area (for which landscaping may be required). Bathrooms and clothes closets should be placed along the driveway side of the rooms. The room layout should follow the usual hotel guest-room arrangement, with the central guest corridor replaced by an access driveway. Convenience, privacy, and rooms that are both quiet and cheerful are the objectives. The shape, orientation, dimensions, and topography of the individual site, of course, may necessitate some deviation from the ideal layout.

Ideally, one side of a row of guest units would take full advantage of the view, with the access drive on the opposite side of the row. Bathrooms on the entrance side would have small, high windows to increase privacy and reduce noise, whereas the guest rooms might have large picture windows to capitalize on the view. An extra doorway on the side with the view might be desirable. (See Fig. 29, 31, 32, 34, 36, 40.)

If the strip of land available for guest units is narrow, either because of dimensions or topography, the best solution is generally to set the units well back from

the road. The effect from the road will be impressive (Fig. 40). If the strip were about 25 ft wider, better results would be obtained by setting the guest units 25 ft back from the parking area, and landscaping the area between.

A level strip on a hillside, even as narrow as 43 ft, can readily accommodate both a drive and a single row of parked cars. Placing each guest room over its parked car solves the problem nicely: The cars are protected from the weather, and each guest is provided with a private balcony (Fig. 41). If the site continues downhill, it may be desirable to sink a guest room into the bank and park its car on the roof (Fig. 42). This arrangement provides privacy and a good view of the valley.

If there is no desirable view and the patronage will be mostly transient, the more economical back-to-back arrangement may be justified, despite its lack of privacy and cross-ventilation. (See Fig. 30, 33, 35, 38, 46, 48.) Two- or four-room units are often arranged with parking space between them, serving to break the monotony and add visual interest (Fig. 30, 31, 34). Another alternative is a four-room unit with all four cars parked in a row (Fig. 35).

Rooms on different levels may be advantageous, depending upon the topography and dimensions of the site, and the number of units required. Guests handling their own luggage generally do not welcome climbing a full story height, but seldom object to half that amount (Fig. 37, 45).

Corridors

An interior corridor will protect the guest in bad weather and be a great help to maid service. With protected inside corridors, a maid is customarily assigned 14 to 16 rooms; if only an outside entrance is provided, one maid would probably handle only 10 to 12 rooms. Moreover, a single interior corridor will make it easier for the management to exercise desired control; the guests, also, will probably feel more secure.

On the other hand, if the only entrance to a room is through an outside doorway, the guest can enjoy the feeling of having a private cottage. That feeling, however, will be appreciably reduced if the open corridor or public walkway is close to the building and protected by an overhanging roof, despite high windows, venetian blinds, or similar remedial devices. Privacy would be greatly improved by placing the public walkway 15 ft or more away from the building, with suitable planting between.

Compare the arrangement of two-story

guest-room buildings with open corridors in Fig. 46, with the one with interior corridors in Fig. 47. Note that the construction requires floor slabs of the same width for each. An advantage of the open-corridor plan is that a quarter of the rooms have direct access to parking. The corridors, however, extend along the only windows, and thus reduce the privacy of all the guest rooms. The plan with the inside corridor offers greater privacy, better insulation from outside noise, and full protection from the weather for guests and maids. Moreover, half its guest rooms have either a private balcony or terrace.

A narrow site requiring two guest floors to secure the necessary number of rooms, may necessitate putting the building on stilts, with parking below the guest rooms. (Such an arrangement, however, increases the building height, and adds unwelcome stair climbing—or elevator problems.) With two stories, two access drives are preferable, one on each side of the building. If two drives are not feasible, however, it is possible to use a central driveway, a solution often employed in garages (Fig. 48). Both guest floors can be served by an interior double-loaded corridor, or by open corridors (one on each side) with a pipe-and-vent shaft between the guest bathrooms.

Standard motels have not yet been built. They have appeared, at times, on drawing boards, but individual circumstances—site conditions, food-service demands, and geographic location—invariably have required adjustments. Before beginning the design, the designer should thoroughly discuss with the owner and operator such matters as the choice between interior or exterior corridors, single or double loading, long guest buildings or two- and four-room units, and one- or two-story structures.

GUEST ROOMS

The motel guest wants much the same things in his room as he would want in a hotel. Reference should be made to previous pages concerning typical hotel rooms: types, sizes, design principles, and representative layouts. A motel will often increase the length and width of a similar room by a foot or two, however, to provide a greater spaciousness than would be feasible in a commercial hotel in the city. Some experienced motel operators say that 13 by 16 ft of net bedroom area is the best minimum size for a room to accommodate two persons.

Kitchenettes

Motel guests who have arrived at their destination often want cooking facilities on

a modest scale. If the motel will cater primarily to overnight guests, however, the probable demand for kitchenettes should be determined by a careful study, involving a check of other motels in the neighborhood. Representative layouts including kitchenettes are shown in Fig. 49.

Complete factory-assembled kitchenettes are available in 30 to 72-in. lengths. Features included are a range top with 2, 3, or 4 burners (either gas or electric), with an oven underneath; a sink, with a utensil storage cabinet underneath; and a worktable area, with a refrigerator underneath. A storage cabinet for china and nonrefrigerated foodstuffs is usually provided on the wall above the unit.

The kitchenette unit may be placed in an alcove sized to fit it, with louvered doors or an equivalent device to screen it off or even lock it up when not desired by the guests. Or a separate room might be provided.

Wall partitions

Partitions between guest rooms should be of any construction that will reduce sound transmission by at least 45 decibels, a reduction that is usually adequate. In wood frame construction, 2 by 4's are often staggered on 8-in. centers, with a sound-insulating blanket between them. In selecting the method of construction, the designer should consider materials, labor, suitability, fire hazards, transmission loss, and cost.

Number of guest rooms

Several motel chain organizations have made careful studies to determine the minimum number of guest rooms that would be economical to operate. Their conclusions run from 64 rooms for the less elaborate forms of operation to 100 rooms for those organizations that intend all guest conveniences and services to be distinctly superior.

SPACE ALLOTMENTS

Space allotments in motels follow, in general, the pattern for allotments in hotels. Data taken from over a dozen motel plans were used to establish the space allotments listed below. Consideration was also given to the typical values for hotels, as listed on previous pages. Space allotments are directly proportional to the number of guest rooms; the figures provided below for a typical 100-room motel can be adjusted to suit any other size. (For a 60-room motel, multiply by 0.60; for 130 rooms, by 1.30.) Other modifications may be necessary to meet individual requirements. No adjustment should

MOTELS

be made, however, for the manager's office and the secretary's office, as each would still need about the same area.

SPACE ALLOTMENTS FOR TYPICAL 100-ROOM MOTEL

Public space	Area, sq ft
Lobby	1,100
Front office	100
Lounge	500
Corridors adjoining	300
Men's toilet for guests	140
Women's toilet for guests	120
Women's restroom	100
Coat checkroom	100
Concessions and subrentals	
Rented stores	2,000
Food and beverage service space	
Dining room (110 seats)	1,700
Coffee shop (70 seats)	1,100
Bar and cocktail lounge (50 seats)	800
Private dining rooms (75 seats)	900
Employees' dining room (20 seats)	260
Kitchen	1,300
Steward's storeroom	300
Walk-in refrigerators	150
Beverage storage	180
China, glass and silver storage	200
Receiving room	200
Garbage room	100
General service space	
Manager's office	130
Secretary's office	90
Accounting office	130
Linen room	350
Laundry	600
Men's toilet for employees	100
Men's locker room	150
Women's toilet for employees	120
Women's locker room	170
Maintenance shops	600
Furniture storage	250
General storage	600
Boiler room	750
Transformer and switchboard room	150

Extra items (if needed)

Garage for motorized lawn mowers and snow plows
Swimming pool filters, chlorinator, pump, and heater
Storage for lawn furniture and recreation equipment

Food service is not a lucrative part of the motel business; money invested in rooms would pay better dividends. The motorist, however, will want food service

handy; if not actually on the premises, then only a step away. He generally dislikes to go more than a few hundred yards to find a restaurant. Therefore, unless adequate food service is already adjacent, it is advisable to provide it.

For the motel requiring strictly minimum facilities, a good solution is the factory-assembled roadside "diner" with a dozen or more seats, which can be handled by a single employee during slack hours. For the more ambitious but still rather small motel with little outside patronage, the best solution may well be a coffee shop, possibly supplemented by a bar. Such an arrangement helps to keep investment and labor costs within bounds. For the larger motel, a dining room, coffee shop, and bar with cocktail lounge may all be needed. If the motel is near a city, private dining rooms are usually added as well. Outside patronage is necessary to make extensive restaurant operations pay. The larger, more spectacular motel restaurants may derive as much as 75 per cent of their business from persons who are not overnight guests (Fig. 50).

Motel restaurant facilities average about two seats per guest room. The ratio varies, however, from one-half to three or more dining-room seats per guest room.

Care should be taken in applying the schedule of space allotments to ensure that, if any food-service area is modified, the effect on auxiliary facilities is considered.

The lobby should be designed to impress the prospective guest favorably and bid him welcome. The entrance must be easily recognizable and accessible. If feasible, the prospective guest should be sheltered from the weather, from his car to the entrance doors. Within the lobby, the registration desk should have a relatively central location, for it is the main control point of motel operation. If the guest, standing at the registration desk, can look through a large plate-glass window and see the swimming pool, attractive landscaping, or a scenic view, room sales will be greatly aided.

Parking

Parking spaces, preferably in separate areas, are generally required as follows: (1) 1 parking space for each guest room (may sometimes be reduced to 0.8 per guest room); (2) 1 parking space for every 5 restaurant seats; (3) 1 parking space for every 3 employees; (4) 2 parking spaces for delivery and service trucks (in addition to space for a truck at the service entrance).

These allotments, of course, should be modified if circumstances warrant it. A motel that is filled to capacity, with a good

restaurant, bar, and banquet business from nonguests, may need 2 parking spaces per guest room. On the other hand, a downtown motel, with parking available nearby and many guests arriving by taxi, might get along with parking space equal to two-thirds the number of guest rooms.

For the design of parking areas in general, see the section of this book on "Parking." Special requirements for motel parking are discussed in the following paragraph.

Parking stalls should be adequate for the largest cars commonly used; 19 ft is the recommended minimum length. Planning for only medium and small-size cars invites trouble. Parking stalls 10 ft wide are recommended; where space is limited 9-ft stalls may be used, but this width should be considered the absolute minimum. Double stripes, 1½ ft apart, between the stalls will result in better centering of the cars within the allotted space. Since almost all motel guests unload baggage from their cars, and reload it upon leaving, adequate and safe space should be provided for this activity. Motel parking lots planned for maximum guest convenience provide parking stalls 11 ft wide by 23 ft long, allowing 4 ft behind a 19-ft car for loading and unloading. Parking spaces under buildings should be 11 ft wide and have a clear height of 7 ft. In the design of sidewalks adjacent to parking areas, consideration must be given to the overhang of the car beyond the curb or wheel buffer; this overhang may be as much as 2½ ft in front or 4½ ft in the rear of the car.

Entrance drive

The turnoff from the highway to the motel should be at an angle of 30 to 45 deg; sharper turnoff angles are inadvisable. The driveway should be 20 to 25 ft wide, and the radius of the curb on the driver's right should be at least 50 ft. If a restricted site frontage should require a right-angle turnoff, then the driveway should be 25 ft wide and the curb have a 30-ft radius. A curb radius of less than 30 ft is inadvisable under any circumstances.

A slope of 6 per cent is the usual maximum for turnoffs from state highways. A slope of 12 per cent is customary for ramps, but can be as much as 15 per cent. The parking lot should be nearly level. The central driveway may be crowned, with a 1 per cent slope to the edges, so that persons on foot will find it relatively free from water after rain or from ice in winter.

Gas station

Motels sometimes include a service sta-

tion where the motorist can conveniently obtain gasoline and oil, and possibly tire, battery, lubrication, and car-washing service. The decision of whether to include a gas station, however, should depend upon its being profitable in itself.

Swimming pool

About 50 per cent of the motels built in 1959 included swimming pools. The trend is to provide pools, even in motels in the downtown area of the city. Although the pool may be actually used by only a minority of the overnight guests, many more will enjoy watching the activities. Thus the pool should be surrounded by a suitable terrace at least 10 ft wide; if a diving board is provided, the terrace should be 20 ft wide in back of the board. Grass areas beyond the terrace are also recommended.

The motel pool should generally be of the recreation type. A free-form pattern, either kidney-shaped or oval, is usually suitable, but of course is subject to topography and the designer's judgment. The minimum size recommended for the pool is 20 by 40 ft, which is large enough for about 15 people in the water and 20 to 30 bathers around the edge. One motel chain prefers a 24 by 48-ft pool. Another chain, operating motels of 150 rooms and more, considers 35 by 75 ft to be the minimum.

A separate wading pool is often provided—sometimes with spray fittings or a small fountain to enhance its appearance. A fairly wide terrace should surround the pool, with benches on the terrace for parents.

Toilet facilities for men and women bathers should be accessible from the pool area. Such facilities are required by law in many states. Provision should also be made, within 40 ft of the deep end of the pool, for housing the necessary water filters, pumps, purification equipment, and heater. A water heater can extend the use of the pool over a longer season.

Other planning considerations concerning the pool and surrounding area include food and beverage service and adequate illumination for evening activities.

The inclusion of a cabana club may be considered, if there is sufficient local demand. In addition to membership fees, the cabana club may bring other profitable business to the motel. Since cabana club members are not overnight guests, however, provision must be made for dressing rooms, lockers, showers, and toilets. The

members will also expect an ample pool-side terrace area with tables and chairs, umbrellas, and reclining lawn chairs, in addition to the cabanas. The cabanas themselves, though, may serve as a windbreak, and thus help to prolong the pool season.

Recreation areas

Although the pool will probably be the most popular recreation area, a children's play yard, and areas for adult games may also be desirable. Some such games are listed below; the dimensions indicate the area for the game, including the usual surrounding border.

Game	Width x length, ft
Shuffleboard	10 x 60
Clock golf	40 x 40
Croquet	50 x 95
Horseshoes	12 x 60
Table tennis	12 x 20
Tennis	60 x 120
Handball	30 x 45

Barbecue facilities may also be desirable. An area of about 15 by 20 ft is generally ample. The play yard for small children should be enclosed by a fence. Suitable modern equipment should be selected and installed.

Indoor recreation facilities may include a television room, one or more card rooms, reading room and library, table tennis, movies, piano, and electric organ. These facilities should be discussed and decided upon in the early planning stages, because it is often impossible to fit them into a completed plan at the last minute.

Landscaping

Landscaping is important—it is one of the things the guest sees first. Well-kept, neatly defined lawns and drives will make a favorable impression; the parking arrangement should be logical and practical. Hard-surfaced walks should be so arranged that lawns may be preserved; retaining walls should be installed to prevent erosion and enhance appearance. The right varieties of trees will provide attractive shade. Undesirable views should be screened by dense plantings, trimmed hedges, stone walls, or louvered fences.

Outdoor advertising

Signs are the most effective means of attracting the attention of prospective customers. Most people stop at a motel because they like its sign.

Signs should be neat, bold, brief, and

distinctive. Their message must be grasped at a glance. The entrance sign should be plainly visible a good hundred yards from the turnoff, with letters at least 18 in. high. Copy should be reduced to a bare minimum, and only unusual services advertised.

A distinguishing emblem, trade mark, or coat of arms should be unique and easily remembered. Select one that can be used at the motel entrance, in the lobby, and on stationery, menus, and souvenir match books. Avoid using too many colors in a sign. Simplicity is effective.

Signs should be durable and suited to the climate of the location. Night illumination is essential, at least for the sign in front of the motel, but care should be taken that guests will not be annoyed by beams of light, glare, flashing off and on, or other features that might bother a person wanting to sleep. The sign at the motel customarily has a "Vacancy—No Vacancy" indication.

Heating and air conditioning

Guest rooms are best served by a central plant, with individual room temperature controls provided. A system favored by some of the more experienced organizations circulates water through convectors concealed beneath the guest-room windows. The circulating water is heated in winter and chilled in summer, the water temperature being varied in accordance with weather conditions. Each guest-room conditioning cabinet has a multispeed, manually controlled, motor-driven fan to blow air over the coils. The guest can regulate the fan speed to vary the rate of heat transfer.

Other parts of the building—such as the lobby, restaurant, kitchen, and employees' quarters—should be divided into "zones," according to their hours of use and type of air treatment needed. Each zone will have its own separately controlled equipment to supply heat or air conditioning. Air conditioning is supplied in the summer for public spaces, restaurant, and bar facilities frequented by guests. Ample exhaust ventilation will be needed for the kitchen and the employees' locker rooms and toilets. Care should be taken to avoid having to operate an entire zone of rooms with short hours of use just to accommodate one or two that will be used many hours a day.

MOTELS

BASIC GEOMETRY OF MOTEL SITE PLANNING

The basic element of design in motel site planning is not the rental unit alone, i.e., a living-bedroom and bathroom, but the rental unit plus a parking space, plus an access roadway, plus a pedestrian walkway, plus a certain quality which can be summed up in the term "amenity." This latter will include outlook, privacy, protection from noise, and "character." All except the last will usually imply space. In the case of outlook one may visually poach on neighboring land, but this will not in the long run be dependable without control over the development of this land.

As the basic element of design is not simple and easily defined, as might at first appear, so in its use it may be equally difficult to classify and analyze. Being composed of so many elements, it will vary greatly from one case to the next. A change in one element will change the whole balance of relative importance. We have therefore attempted to simplify and sharpen the most common requirements of this site geometry by concentrating upon a typical rental unit strip of near-minimum dimensions placed in a number of different and typical situations to demonstrate the considerations which should control the site planning of a small roadside motel. These diagrams will also provide the data for a preliminary quick check on site area and shape, as related to possible density of development and efficient utilization of the land with various types of plans.

The Rental Unit Strip Dimension This becomes the basic planning element in these simple site plans, is made up of the rental unit, a pedestrian walkway, parking space, and access roadway. Not shown here, because too difficult to measure or reduce to a type, is amenity space, which includes outlook. The size of each of these elements will vary from one case to another, but each dimension shown here is typical.

A Shallow Site Parallel to the Highway This will almost inevitably be best served by an elementary type of strip plan with front parking. Such a site is too narrow for the units to be turned at right angles to the highway, and if they were moved far enough forward for rear parking, the rooms would be unpleasantly close to the highway (Fig. 1).

If there is an opportunity for some outlook in the rear, even onto someone else's property, then the plan can be greatly improved by keeping access and parking on the highway side and opening up big outlook windows to the rear.

A Narrow Site at Right Angles to the Highway This must usually be enough wider than the minimum strip dimension to allow for the side yards normally required by local building and zoning regulations. There is nothing to prevent one or both of these side yards from being incorporated into the parking space (Fig. 2).

For more intensive use of this sort of site, the strip is normally turned at the end to form an L. A corresponding wing might be added at the highway end but is seldom done because it would close off the motel from the view of motorists on the highway. Such wings upset the parking ratio of a typical strip; space must be found for these extra cars possibly at the rear of the wing units.

If the view to the rear beyond the lot line is pleasant, then it would be better to do without the rear wing. If the view is undesirable, the wing can effectively close it off, and the inside of the L can create an environment of its own.

For Greater Density On a similar deep narrow site at right angles to the highway, a common plan is to pile the units two or more stories high, facing outward from a central bathroom spine. Access and parking is on each side, with access balconies along the face of the upper stories, so that pedestrian traffic is channeled immedi-

ately in front of the outlook windows, killing all privacy.

The parking space must be enlarged to take care of the units above the first floor. The side yards can be usefully employed as part of the parking area. But if the second-story access balconies are reached by stairs at each end of the rental unit block, then parking space for the second-story units is most convenient if concentrated in this same area at each end of the building (Fig. 3).

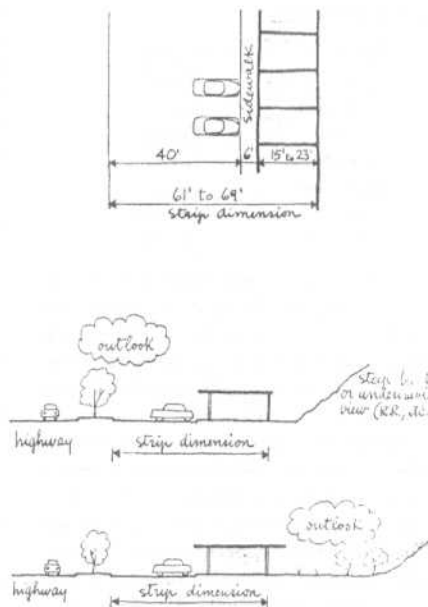

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Fig. 6

Fig. 7

Fig. 8

The Bathroom Spine Plan May Be Improved If all parking space is concentrated at the highway end of the long narrow lot, each unit has a private fenced garden. Access is by a perimeter covered walk (Fig. 6). Plan suggested by Mayfair House, Carmel, Calif.

If Parking Need Not Be at the Unit Entrance A larger number of rental units can be fitted more successfully onto a long narrow lot by concentrating the parking area at one end. Where the central garden court becomes very narrow (Fig. 4), the only way to obtain privacy of outlook is to

Fig. 9

Fig. 10

a

b

c

d

Fig. 11

divide it down the center with screens or high planting.

In the plan (Fig. 5), the disadvantage of a road down the center is counterbalanced by the convenience of unloading baggage at the entrance.

Road Parking Strip and Carport Strip Compared Alternating unit pairs and double carports gives a longer but narrower strip than the conventional. For a more spacious lawn and easier drive-in, the carport strip is in practice usually made wider than shown in Fig. 7.

It's the Corners That Count When a strip plan is bent into a court, the more corners, the more waste of space; often this is of small importance. With parking on the outside front (Fig. 8) there is space for a car outside the door of each unit. With parking on the inside front (Fig. 9) there cannot be space enough for all the cars expected and corner units are left without parking stalls. The visual values of the open corner could well be combined with a road through, so that the U becomes two L courts (Fig. 10). The larger a plan, the less important are the corners.

The U Court Comes in All Patterns, All Sizes As shown in Fig. 11.

a. Opens an attractive central garden court to the highway, using this as an advertising feature.

b. Almost closed to the highway, is of less advertising value, but guests have more quiet and privacy.

c. By parking inside the U, the same number of units can be packed onto a smaller lot. Noisy and without privacy. Worst on a small scale.

d. For more units the U becomes E. Center line does not have parking directly outside door but can be served by interior corridor or covered walk.

Many architects and engineers who design office buildings will no doubt inevitably be engaged by a client who expects to have a computer, or more correctly electronic data processing (EDP), system installed in his building. While the needs for particular systems will ordinarily be highly individualized and complex, some general principles concerning the architectural and engineering aspects involved in planning a building for these machines can be set down. In this way, one who is faced with the design of a building which will house an EDP system may provide himself with some of the background he will need for the more detailed considerations he will be faced with later.

The use of computers for scientific or engineering calculations is well known. The use of EDP systems for the automation of ordinary business operations such as inventory controls, bank operations, clerical functions, and the like is also familiar.

EDP systems are highly demanding of the architect and his consultants. The machines refuse to function under conditions of high humidity and high or low temperature which employees might put up with. The installations are heavy and place concentrated loads on building floors. Large areas are required for the placement of many of the systems, and for the maintenance and servicing of the machines. Electric power with low variations in voltage and frequency must be furnished to the systems. Many of the systems require a raised or double floor to accommodate the large number of cables interconnecting the machines. Because of the nature of the problems involved in the design of office building spaces for EDP installations, an examination of some of their more important aspects should be of value.

The architect working on an office building which will contain an EDP system will naturally turn to the companies that produce them and to consultants who specialize in the field for detailed answers to the specific design problems. However, an examination of some of the more general and important aspects of planning should give him some background for later and more detailed study.

Electronic Data Processing System

The National Office Management Association defines a computer as "a device capable of accepting information, applying prescribed processes to the information, and supplying the results of these processes . . . from internally stored instructions, as opposed to calculators on which the sequences are impressed manually from tape, or from cards."

This is to say that computers are devices

which may receive their original instructions from tape or cards, but which also store required information within themselves. The experts in the field have tended to use the word *computer* to specifically describe devices which perform problem-solving calculations but to employ *electronic data processing system* (EDP) or more simply, *data processor*, to describe the general type of the devices.

The schematic floor plans in Fig. 1 give some indication of the units which might be used to make up three different electronic data processing systems. In practice, numerous variations of the above are possible for different purposes and problems. The plans shown are not intended to be typical, but only to serve as examples of some of the principles involved.

EDP Organization

In the simplest terms, an EDP system is composed of four major parts: input, storage (memory), processing, and output. In practice, the input will ordinarily be in the form of instructions sent to the machine by a person operating a keyboard, from punch cards, or from punched paper tape. The newer and more sophisticated high-speed systems often employ magnetic tape inputs. The storage or memory units are all magnetic devices. They include drums, disks, tape, and a system of magnetic cores. The term "solid state machines" comes from the basic characteristics of transistors. Output components are similar to the input devices. Results may be fed to keyboards, punch cards, punched paper tape, or magnetic tape. In addition, it is possible to feed the output information to high speed printers.

Schedules and Timing

It is imperative that planning for an EDP installation should begin very early. Programming of the operations the machines are to perform often takes a year or more before the actual components of the system can be selected. A year or more will usually be required between the time the system layout is approved and delivery of the equipment. Architectural and engineering considerations concerned with the building itself require a certain amount of time. The total number of months needed from the time of the decision to install an EDP system will, of course, vary with the individual problems. But, in all cases, the complete process will be spread over quite a long period. It is imperative that adequate time be allowed.

General Requirements

The first consideration in the planning of an EDP system is the provision of adequate space of the particular kind required. Proper and adequate power must be provided. Air conditioning requirements must be determined (often six times as much as for a normal office will be needed). Space must be provided for housing the air conditioning equipment. Ceilings must be high enough to allow machine

installations and, more often than not, a hung ceiling and raised floor will be necessary. The floors must be designed for the high loads to be placed upon them.

Work flow to other areas is highly important in order to obtain the utmost efficiency. Flexibility and expansion problems are acute, since EDP has a way of outmoding itself very quickly. Also, experience shows that many companies begin with systems performing limited functions but soon discover other operations that lend themselves to automation.

Space Planning

The areas required for EDP installations vary considerably. For example, one of IBM's more limited capacity systems requires about 370 sq ft, while the same company's large system may take up 3,500 sq ft. Actual space requirements for a given installation can be finally determined only by a layout of the work flow and of the machines themselves. In addition to the space for the system proper, auxiliary areas are needed for air conditioning equipment, testing, storage, and the like. Space is often required for printer form stands, card files, work tables, desks. Storage must usually be provided for permanent master document files, EDP cards (or in newer machines, magnetic tapes). These areas should be carefully located to minimize unnecessary travel time. A bulk storage room is usually required for the storage of spare filters, transformers, and other large parts.

Floor Strength and Construction

The units which compose an EDP system are heavy. Point loads on the floor may often run as high as 1,000 pounds. Even when the loads can be distributed, it is usually necessary to design the floors for 150 psf loadings, or more. As EDP installations become more common, it may be feasible to construct some buildings with all of their floors stressed for the loads of these systems. In most cases, it probably will not be economical to do so. In any case, EDP system locations will require close study and selection, followed by design for the loadings to be encountered.

Currently, the preferred method of solving the load distribution problem is by the provision of a secondary floor raised over the building floor slab. An installation of this type may have other important advantages: interconnecting power cables and receptacles may be concealed, yet remain easily accessible, the space between the floors may be utilized for housing air conditioning ducts or plenums, future changes in the layout may be effected with a minimum of lost time and expense, machines may be added easily.

While a secondary floor with raceways may be employed, a free access type, allowing complete directional freedom, is preferred. This type of floor is composed of square or rectangular panels, supported at their edges on a structural grid, and raised to the required height on pedestals of metal or other material.

The material in this article was developed from data supplied by the Data Processing Division, International Business Machines Corporation, White Plains, N.Y., and Air Research Associates, New York, N.Y. and was published in *Office Buildings*, McGraw-Hill Book Company, 1961.

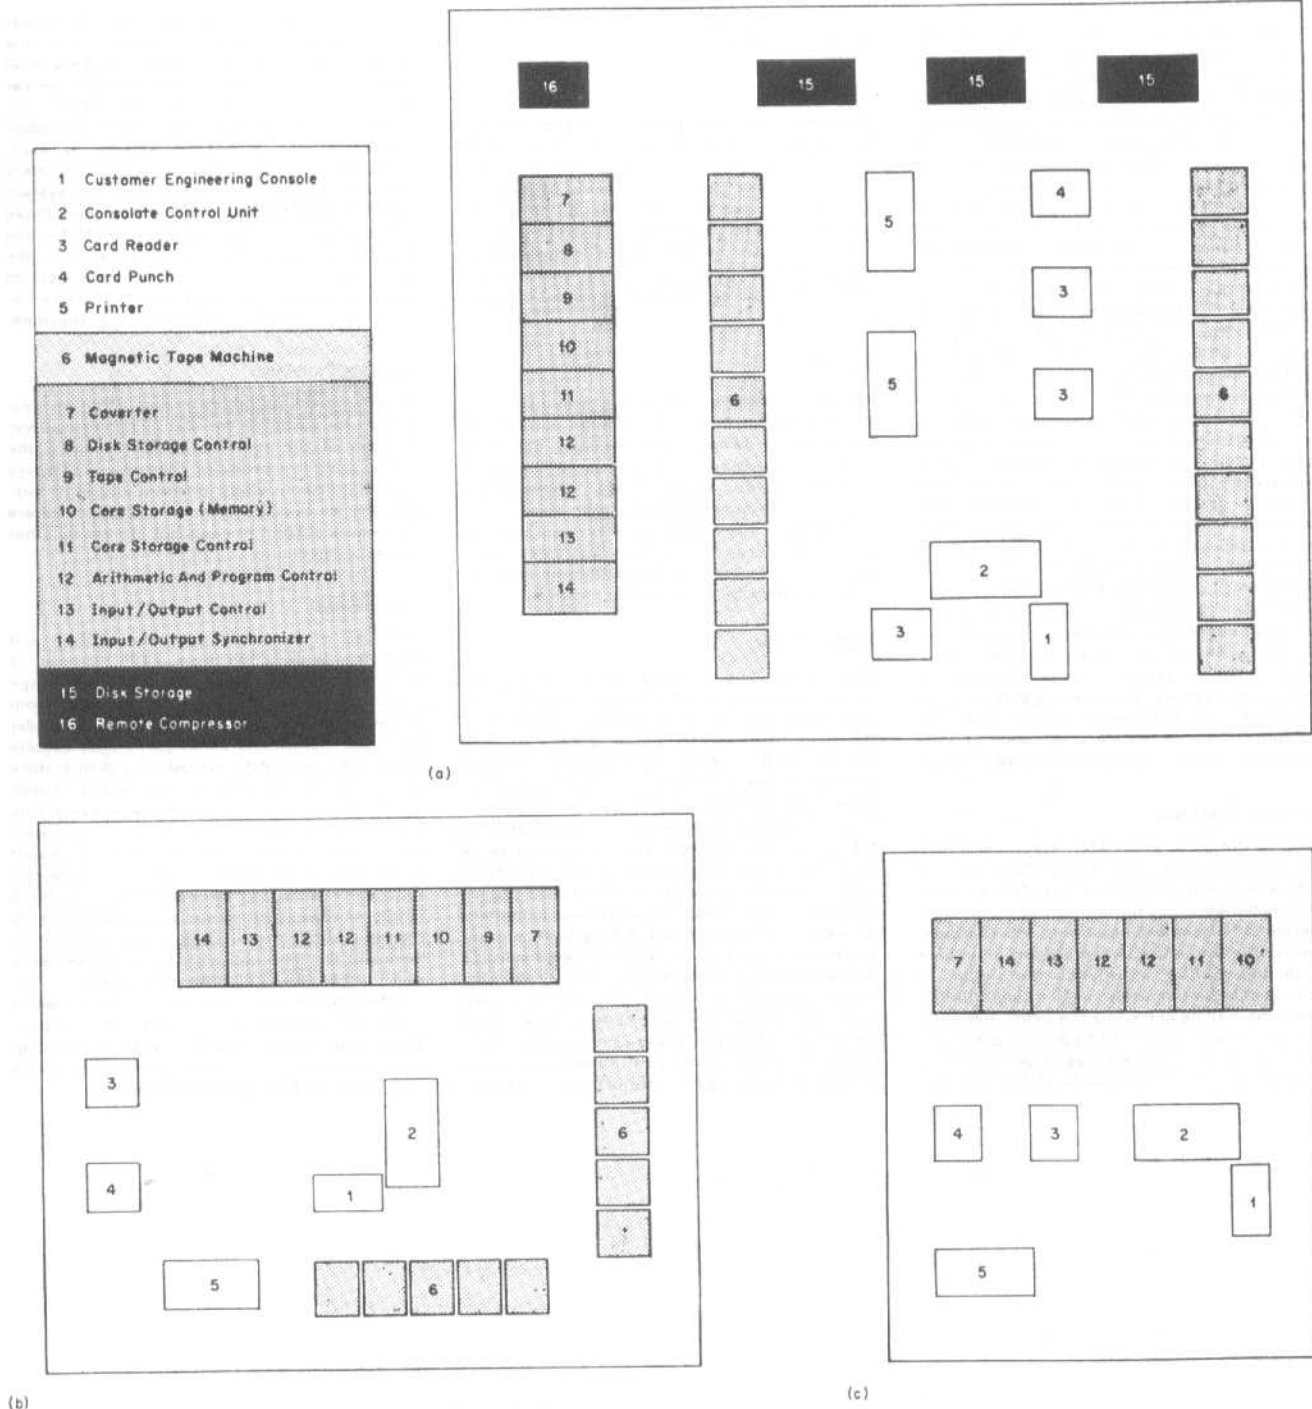

Fig. 1 (a) Schematic layout of tape/disk storage EDP. (b) Schematic layout of tape EDP system. (c) Schematic layout of card EDP system.

Air Conditioning

Electronic data processing systems require very close control of air temperature, humidity, and dust. If any of these is not held within certain prescribed limits, the machines cannot perform. Thus, the provision of adequate air conditioning is necessary. If the cooling of an office space fails, its occupants might

continue to do their work, but EDP cannot. Because of this, the recommended, and usual, solution is the provision of a separate air conditioning system serving the EDP system alone. This system will be required to operate on the cooling cycle all year round.

In many cases, the preferred location for the EDP air conditioning system is in a room adjacent to the data processing machines them-

selves. However, if lines must be run to a cooling tower many stories away on the roof, this may prove too costly. In some cases, the tower might be located on a ledge or setback roof. Those who have had considerable experience in the design of EDP installations recommend installation of as much standby equipment as possible. Since EDP rental or purchase costs are so high, any time when the system is

COMPUTER (EDP) FACILITIES

inoperative can be financially disastrous. It will often prove more feasible to minimize shutdowns through the use of standby equipment than to risk costly delays.

There is considerable variation in the air conditioning requirements of various EDP systems. For example, one comparatively small system dissipates heat approximately equivalent to five tons of air conditioning while with the same company's large system, heat dissipation equals about 33 tons. The IBM 7070 requires about 11 tons of air conditioning. When this machine is in operation, the temperature must be maintained in the 65 to 90°F range, and the humidity between 20 and 80 percent. When inoperative, power off, the limits are 50 to 110°F and 0 to 80 percent RH. High efficiency filters are required for use with these machines. If a mechanical filter is used, it must be rated at a minimum of 20 percent efficiency by the Bureau of Standards discoloration test using atmospheric dust. Electrostatic plate type filters must be rated at 85 to 90 percent efficiency by the same test. Special filtration will be necessary if the installation is exposed to corrosive gases, salt air, or unusually severe dust conditions.

Companies producing EDP systems recommend the installation of temperature and humidity recording instruments. Through the use of the records provided by these instruments, it will be easier to ensure that the air conditioning system is operating continuously with the required efficiency. In this way, correct functioning of the electronic data processing system itself may be more nearly assured.

Acoustical Treatment

Many of the units in an EDP system produce considerable noise. The worst offenders are such components as the card machines, printers, and blowers. For the comfort of the system operators, acoustical treatment of the area is desirable. The acoustical problems in an area containing an EDP installation are similar to those in other moderately noisy office building areas and may be solved by the usual methods. However, attention should be paid to the vibrations set up by the machines. Floor and wall construction should be capable of retarding the

transmission of the vibrations of the machines to other areas of the building.

Illumination

A minimum average general illumination of 40 footcandles measured 30 in. above the floor is recommended by systems manufacturers for all machine areas. Low levels of illumination are required for easy observation of various console and signal lights. Therefore, direct sunlight should be avoided. In larger installations, general lighting should be zoned, so that portions of the lighting may be turned on or off as required.

Vibration

An EDP installation ordinarily cannot be made in an area that is subject to large amounts of vibration. In general, the machines can withstand a sustained vibration up to 0.25G ($G = \text{gravitational acceleration}$). Intermittent vibrations somewhat greater than this can be withstood if their frequency is less than 25 cycles per second. In more extreme cases, steps for overcoming the problems may be recommended by the manufacturers.

Electric Power

Data processing systems place heavy loads on the electrical system of an office building. The system requirements for circuit flexibility, the need for power source dependability, and safety requirements further complicate electrical design. Exact specifications vary considerably for various installations. However, a look at the requirements for one system, the IBM 7070, might serve as an indication of the general needs. The 7070 system operates on a 208- or 230-volt, 3-phase, 60-cycle supply, and requires approximately 37 kva. The source voltage may have a total variation of ± 10 percent of the rated voltage including transient and steady state. Frequency must be within $\pm \frac{1}{2}$ -cycle. Both 60-cycle and 400-cycle power are distributed within the system, the 400-cycle being produced by a converter contained in the EDP installation. Line-to-line voltage and frequency tolerances

within the system are the same as the power source tolerances. Separate feeders from the main distribution panel of the building are most often used. However, if the building power cannot be maintained within the tolerances, a separate transformer or motor alternator may be necessary. If a transformer is used, it should be fed from the highest primary source available. The data processing system feeder should feed no loads other than those of the system. The distribution panel for the processing system should be located in the EDP area. Ordinarily, all units of the system are designed for cable entry from the floor or from under the floor beneath each machine.

Lightning Protection

Manufacturers recommend that lightning protection be installed for the secondary power sources of the systems in cases where the utility company provides lightning protectors on the primary, where primary power is supplied by an overhead power service, or where the area is subject to electrical storms or other power surges.

Tape Storage

The use of magnetic tape for feeding and receiving information from EDP systems is rapidly becoming more commonplace. Tape must be protected from dust, and from extremes of humidity and temperature. Under the usual conditions of frequent use, acetate base tapes should be stored at a temperature of 65 to 90°F, 40 to 60 percent relative humidity. If exposed to temperatures outside this range (from 40 to 120°F) for more than four hours, tape should be hermetically sealed in dustproof containers, and subsequently reconditioned in the atmosphere of use for a length of time equal to the time spent outside the use atmosphere. Other tapes (polyester base and the like) can withstand temperatures of 40 to 120°F and 0 to 80 percent RH.

When not in use tapes should be stored in dustproof containers in a vertical position. Tapes must not be placed in contact with magnetic materials or subjected to magnetic fields of greater than 50 oersteds intensity.

Fig. 1

By FRANK MEMOLI

The Site

The site for a funeral home should be located strategically with respect to present and future business patterns and be accessible by public as well as private transportation. A quiet location out of sight of hospitals and other organizations that might find the view of a mortuary objectionable is required, as is the availability of cemeteries and churches. Utilities should be readily obtainable.

In order to accommodate the building with parking and landscaping, and to provide for possible future expansion, a site 2 acres in area with at least 300 ft of frontage is recommended as minimum. Preferably the site should run from street to street, but where this is not possible, a corner location is acceptable.

The Building

Some specific recommendations can be applied to the building as a whole. The building should lend itself to future expansion in the event that expansion becomes necessary. On the exterior, provision should be made for exterior building lighting and a dignified sign. All service areas (loading, delivery, etc.) should be properly screened from public view. If an elevator is used, the loading dock must be at proper truck-gate height.

On the interior, all service deliveries must be accomplished without disruption of normal operations. All doorways through which caskets will pass must be at least 48 in. wide, and the corridor system must be free of sharp, narrow turns.

Parking

An ample and efficient parking facility is essential. It should provide parking space for one car for every four places of seating capacity plus one reserved space for the clergyman. A reasonable amount of reserve land for future parking facility expansion should be available.

The parking area should be freely accessible, with separate entrances and exits. Separate and clearly marked facilities should be made available to different groups such as family, cemetery, funeral service, staff, and visitors.

The area should be so planned as to facilitate cleaning, drainage, and snow removal where appropriate.

Reception Area

This area is a focal point of the funeral home and, while it affords access to all other areas, it must also protect these other areas against intrusion. It should have an air of comfort and welcome. In the event that no foyer or vestibule is practicable, this area will serve as a buffer against weather, dirt, and noise. In some instances it may double as a smoking lounge.

The reception area should be a unit in itself, relatively free and unencumbered, with all unnecessary doors eliminated.

Consideration should be given to the desirability of two reception areas—one for services and one for business (Fig. 1).

Selection Room

This room should be privately accessible from the arrangement office and conveniently located, especially for elderly or disabled persons. It should be relatively free from noise and other disturbances, protected from public view, and unavailable to the merely curious.

In sizing the selection room, allow 60 sq ft per casket to be displayed. The floor space should be free from unnecessary partitions and obstructions and the wall space relatively large and unbroken. Windows are not a necessity, but if provided, they should be screened from public view.

Built-in display cabinets for garments and urns may be necessary, as may be a separate vault selection room.

As with all rooms into which caskets will be placed, all doors should be at least 48 in. wide.

In case of emergency, the selection room may serve as an auxiliary chapel. It should be designed with this in mind.

Reposing (or Slumber, or State) Rooms

These rooms should be readily accessible from the preparation room, the chapel, and the reception area and should be at least 12 by 14 ft in size. They should be adjacent to one another, separated by soundproof folding doors, for use in combination. When used separately, each room should have reasonable privacy and be individually accessible to callers. The rooms may be of different sizes but must all be sufficiently flexible to double as chapels and to accommodate a variety of religious rites. The reposing rooms must all provide for attractive casket placement and floral displays.

Preparation

This room should be located well apart from public areas of the building, convenient in terms of movement of bodies, and readily accessible to the reposing rooms. If the preparation room is not on the ground floor, an elevator should be nearby. When sizing, allow an area of 14 by 16 ft for each one-table room. Each such room should contain sufficient convenient cabinet space, a sink or drain bowl at the foot of each table, arrangement for an aspirator, hot and cold water sources at the head of each table, convenient sink and sterilizer, cleanup facilities (possibly including a shower), and adequate clothing hooks and storage space. In addition to these, facilities for dressing and cosmetizing may be desired. Room walls and floors should be tiled and floor drains provided. Wherever possible, windows should be omitted. Convenient and sanitary

facilities for refuse disposal are required and provision for emergency power and lighting may be desirable.

Chapel

The chapel must be directly accessible from the main entrance or lobby and convenient to the parking area as well as in terms of post-service movement of casket, flowers, etc. A minimum clear ceiling height of 10 ft 6 in. is required. The space should be relatively free of columns and other structural elements. It should allow for a wide aisle and a clear view from all angles. The chapel must accommodate all types of religious services, and in appearance it should be sedate, dignified, and comfortable. Provision must be made for a pleasing setting for the casket, a pulpit or rostrum occupying a dominant focal point, and an unobtrusive but effective music system.

In addition to the above, the following ancillary areas will be needed: a private family room, a small study for the minister and nearby areas for overflow groups, congregation of pallbearers, and chair storage.

Family Room

The family room should be screened from public view, have a private entrance and exit, allow the family to see the casket, and enable the family to be aware of all that is going on. It should be large enough for the average family with the possibility of being adjusted in size to accommodate the occasional larger-than-average family or to serve as a reposing room. Rest rooms and first-aid facilities should be nearby. The organ should be reasonably distant from the family room.

Music Room

The music room should be located adjacent to the chapel, with the sound source at the front of the chapel but so designed as to prevent extraneous noises from drifting into that room. The musicians should be able to enter the music room without disrupting services and should have a view of the clergyman, funeral director, or signal light in order to follow cues. All music facilities will be located in this room, with ample space for organist, vocalists, standby facilities such as a piano or other self-sufficient instrument (in case of a power failure), and storage for recordings if used. Appropriate provision should be made if services are to be recorded.

Arrangement Office

This office should be private enough to be free of all disturbances during an arrangement and should afford direct private access to the selection room. It should be separate from the general business office but in reasonable proximity to it, and should be so designed as to double in use for a second purpose. It should contain a closet for wraps and have ready access to drinking water and first aid.

Adapted from *Checklist for Mortuary Planning*, by Dr. Charles H. Nichols, Director, National Foundation of Funeral Service, Evanston, Ill.

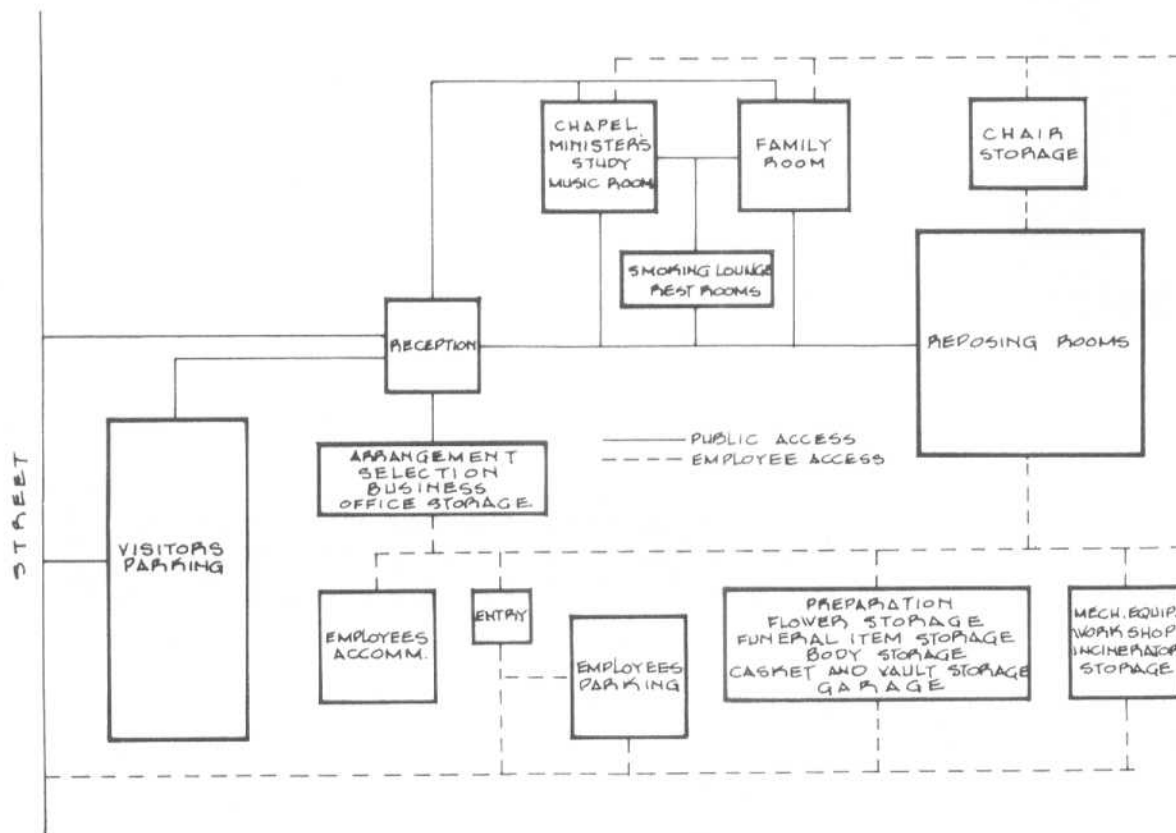

Fig. 1 Funeral home flow diagram.

Business Office

This area should be planned as a reasonably soundproof central control post for the entire operation. It should be readily but separately available for those who come on business only and should give convenient access to private offices, if any. Typical activities which occur in this office will be typing, filing, bookkeeping, mailing, accounting, etc. A safe will be required, as will sufficient storage space for business records.

Minister's Room

This quiet, secluded room must be directly accessible to the minister but to no one else. It should afford direct access for the minister to the front of the chapel. It should be a convenient place for the clergyman to review his notes and to robe and disrobe. Toilet facilities must be in close proximity.

Smoking Lounge

This room will be apart from the service areas of the mortuary but may be combined with the rest room facilities. It should be readily accessible to visitors and convey an impression of comfort and informality.

Rest Rooms

Like the smoking lounge, these rooms should be apart from the service areas of the mortuary but may be combined with the smoking lounge.

They must be conveniently located, especially with respect to the resting rooms, and accessible to visitors.

Employee Accommodations

This area must be reasonably remote from the public areas of the mortuary and should be a place where employees can relax during off-duty periods or periods of waiting (possibly combined with the smoking lounge in smaller establishments). It should be equipped and furnished for rest, relaxation, and recreation.

If employees sleep on the premises, the sleeping rooms should be adjacent to this rest area. If a man with a family lives on the premises, a comfortable apartment must be provided.

Storage Areas

A garage apart from the mortuary and equipped for indoor car washing, general repairs, and maintenance is required.

Dry, above-ground storage for caskets and vaults must be provided and should be easily accessible. Movement from this area to the selection room should be direct.

A cool, moist room with a sink and at least 6 by 10 ft in size is required for flower storage and should be equipped for the trimming and proper care of flowers. It should have cabinets for the storage of racks, vases, utensils, etc.

Provide a room for chair storage, preferably off the chapel.

Provide a room or rooms for storage of

funeral items, preferably near the resting rooms.

Provide ample closets for miscellaneous storage purposes, as well as adequate wardrobe facilities throughout the building.

Provide permanent fireproof storage for valuable records as well as ample storage areas, accessible to the main office, for office and printing supplies.

Provide separate storage, accessible to the cemetery service trucks, for equipment.

Provide a general storage room for miscellaneous and catch-all purposes.

If necessary, provide storage facilities for the short-term storage of bodies.

Utility Rooms

In most cases a mechanical equipment room containing heating and air conditioning equipment, set apart from the service areas, will be required.

If desired, a woodworking or carpenters shop can be provided, as well as an incinerator.

Special Facilities

In addition to required facilities listed above, the following special facilities may be needed or desirable: a crematory, a Columbarium, a lodge room, a community or civic room, kitchen facilities or coffee bar, guest apartments, guest bedrooms or a single guest room, a child's selection room, dressing and cosmetizing rooms, and an emergency power and lighting system.

INTRODUCTION

An airport is like a total city devoted to dynamic movement. It comprises many varied structures that facilitate passenger and cargo movement, maintenance, and aircraft control, and other structures that provide for auxiliary support functions. The very nature of an airport's complexity makes it necessary to isolate its segments for design purposes. It is therefore the intent of this article to isolate primarily the passenger functions and to discuss how they tend to operate at an airport and what their general relationships to a community are.

Airport Operations

First, all the movements and functions of the passengers, the cargo, and the airline employees to and from an airport are regulated by a printed schedule. That is, the action that each discipline will follow is begun on the basis of this schedule, and the passenger's actions are based on the printed timetable of the airline he has chosen to fly.

The cargo movements to or from the community are based upon the normal working hours of the community. This working schedule is generally in conflict with the flying schedule of the airline. Therefore it requires special correlation by the airline.

The employees' working hours are predicated upon the functions of each discipline as it relates to the schedule. Therefore, all major elements of movement to and from the airport tend to take place upon a preestablished, programmed basis. However, the technology of the aviation industry changes so rapidly that a secondary but most important consideration arises. The technology can, overnight, change the preestablished schedules, thereby changing all relationships and movement to and from the airport. This occurs in three ways:

1. The aircraft manufacturer has demonstrated his ability to produce new aircraft with greater speeds, capable of carrying a gross load comparable to that of existing aircraft. Therefore, with the faster aircraft, time zones that had one relationship now have another. This then affects the predetermined schedule and all the related disciplines.

2. The ability to change and increase the payload of the aircraft for both passengers and cargo creates a new condition. This requires a revision of function and all disciplines in order to accept greater numbers of passengers and increased cargo movement within a short period of time. It also creates voids during other periods of the day.

3. This condition results from both increased payload and increased speed. This will totally change the predetermined schedule.

Therefore, a constant program factor in the development and design of all functions and disciplines is the fact that flexibility for future growth and expansion must be incorporated.

There is another factor to be considered within the design program, and that is the on-time record of aircraft as related to the printed schedule. The actual arrival and departure times are subject to weather conditions, me-

chanical difficulties, and other special considerations that will arise from time to time.

The extent of on-time arrival or departure by aircraft and the extent of deviation from the schedule must be carefully evaluated. The airlines themselves afford the best source of information related to this problem. Although the scheduling and on-time record is good, a 10 or 15 percent deviation can raise havoc at an airport; therefore, consideration must be directed toward the capability of handling the peak condition plus an overload factor for deviation from the schedule. No two airports function in the same manner. The over-

load factor must be evaluated separately. However, the designer must use caution and be aware of the fact that peak capacity may be reached only at two or maybe four hours a day, depending upon the airport, and for the remainder of a 24-hour day, selected elements of the airport operate at very low efficiency. Restraint must be exercised to carefully control the amount of structure that is designed so as to provide an economically correct solution.

An airport functions as a transfer point between air vehicles and ground vehicles. There are numerous types of air vehicles designed for various functions. An examination of Figs.

Fig. 1 Aircraft range.

MILES (1,000)

AIRPORTS AND TERMINALS

1 to 10 will show some of the types, their sizes, their capacities, and their development trend.

The ground vehicles at an airport can take many forms. They are motor vehicles utilized as passenger cars, trucks, etc.; rapid transit systems of many descriptions; and special loading vehicles which can be utilized for supplementary transfer within the airport proper. The transfer point (passenger terminal) is generally a building structure or structures, and it is to its activities that we will primarily address ourselves. However, the understanding of the operation of this type building would be incomplete without the knowledge of a series of systems that must be correlated to its activity.

The activity is divided into public and non-public functions as an operating reality. The public function for both arrival and departure of passengers is described in Figs. 11 to 13. The nonpublic function is described in Figs. 14 to 16.

Relationship to Community

The operation of the airport is no different than the operation of a small city and is inherently set in motion by economic factors. It is also influenced by the fact that for the traveling passenger, air transportation makes the period of inconvenience considerably shorter than it would be with other conventional systems. However, an airport cannot be an island unto itself, and it has a great impact on a community. The very size of the airport affects the surrounding community. The careful planning of buildings and site location afford the potential for improving the environment and economics of a community.

There are many problems of noise, air pollution, and ecological balance that can be minimized or eliminated by proper site planning and building design. The community is affected by the working population of the airport, by the introduction of new industry, and by the economic impact of same.

The economic health of the airport and the architect's attempt to stay within the bounds thereby established cannot be overemphasized. The successful operation of the airport will demand total cooperation with the surrounding community. It thereby follows that every effort to establish proper working relationships among the many varied systems within the airport will be predicated upon a successful relationship with the surrounding community.

GLOSSARY

AMENITIES: That part of a terminal building housing convenience, service, and diversion facilities for the passengers, tenants, and public.

AVERAGE PEAK HOUR: The peak hour of the average peak day. The peak hour is the one-hour period of any peak day during which the highest percentage of the day's traffic is experienced. The average peak day is the average of the top 37 days (10 percent) of a year in terms of traffic volume.

BAGGAGE DIVERTER: A mechanical device for transferring baggage from a moving conveyor belt to a baggage claim counter in such manner that the baggage is evenly distributed along the baggage counter.

BOARDING CONTROL POINT: The point at which a passenger's credentials are inspected to assure that he is authorized to board a particular flight. Normally, this point is located in the vicinity of the gate from which the flight will depart.

Fig. 2 Passenger-aircraft capacity growth trend.

Fig. 3 Gross-weight growth.

Fig. 4 Overall-length growth versus year.

Fig. 5 Wingspan growth versus year.

Fig. 6 Overall-length growth versus gross weight.

Fig. 7 Wingspan growth versus gross weight.

BOARDING PASSENGER: Any originating or connecting passenger authorized to board a flight.

CONNECTING PASSENGER: A passenger who arrives on one flight only for the purpose of transferring to another flight to reach his destination. These passengers are broken down into two categories: intraline and interline passengers.

CUSTOMS: This is an area under federal jurisdiction through which passengers arriving from foreign countries are required by law to pass in order to make a declaration related to baggage which is accompanying them upon entry to the United States. This area is used for receipt of a declaration and/or examination of baggage. If duty is required; the customs agent will receive same in the customs area. Special attention must be paid to the design of this area because of changing techniques of operation.

DEPARTURE ROOM: An assembly area, including the boarding control point, located at a gate position(s) for passengers pending availability of aircraft for boarding.

DEPLANING: Any passenger, cargo, baggage, visitor, etc., which is related to the unloading from an arriving flight.

DOMESTIC PASSENGERS: All passengers traveling in the United States or its territories are considered as domestic. Foreign nationals within the confines and territory require no special checking and operate as domestics.

ENPLANING: Any passenger, cargo, baggage, visitor, etc., which is related to the boarding of a departing flight.

FIS: FIS is an abbreviation for Federal Inspection Services. It is utilized as an all-inclusive term for the U.S. Public Health, Immigration, and Naturalization Service, the Department of Agriculture, and U.S. Customs.

GATE: A location to which aircraft are brought for the purpose of discharging and loading passengers and their baggage.

GATE CONCOURSE: An extension from the main terminal building primarily intended to provide protected access for passengers between the main terminal building and the gates. In addition to the passenger corridor, the concourse may include airline functional areas and minimum consumer services.

GROUND TRANSPORTATION: The independently operated transportation vehicles scheduled for passengers' use between airports and the areas served thereby is called ground transportation.

IMMIGRATION: This area is devoted to the examination of passports of United States nationals and aliens seeking to enter the United States. Consideration for design and function of this area must be correlated with federal authorities.

INTERLINE CONNECTING (ION): A term used to describe passengers and baggage which arrive on the flight of one airline and depart on a flight of another.

INTOWN TERMINAL: A facility located apart from the airport, usually in the downtown area of the city, at which passengers may be processed, baggage is checked to passengers' destinations, and from which ground transportation is provided.

INTRALINE CONNECTING (ION): A term used to describe passengers and baggage which arrive on one flight and depart on another flight of the same airline.

IN-TRANSIT PASSENGER: If an internationally bound aircraft stops at an airport for refueling or discharge of passengers and a remaining number of passengers are to be detained in the aircraft for another destination.

AIRPORTS AND TERMINALS

Fig. 8 Ramp area trend.

Fig. 9 Passenger doorsill-height trend.

tion, the convenience of providing a totally segregated lounge facility may be warranted for the continuing passengers. This facility is referred to as an in-transit area. No FIS inspection is required, but security of the area is important.

LONG-HAUL. A term used to define flights or traffic which travel over a relatively long distance as opposed to those which travel over a shorter distance. Normally, long-haul passengers arrive at their originating airport earlier than short-haul passengers, carry more baggage than short-haul passengers, and are accompanied to or are met at the air-

port by more persons than short-haul passengers.

ORIGINATING PASSENGER: A passenger who is starting his trip.

OUTBOUND BAGGAGE ROOM: The area to which checked baggage of originating passengers is delivered for sorting by flights prior to its being dispatched to the aircraft for loading.

PUBLIC HEALTH SERVICE: The function of the Public Health Service is to determine whether an arriving passenger will present a health hazard to the general population. This may require inoculation, special exami-

nation, and possibly quarantine. Design requires correlation with federal authorities.

READY ROOM: An area adjacent to the normal work areas in which personnel whose duties are performed out-of-doors may assemble, be protected, and from which they may receive their work assignments. These rooms should be concealed from public view.

SELF-CLAIM BAGGAGE: A method under which passengers have direct access to terminating baggage in a controlled area. As passengers leave the area, an attendant retrieves baggage claim checks and matches them to strap checks to assure that passen-

Fig. 10 Estimated jet exhaust characteristics; breakaway thrust.

gers have selected only baggage to which they are entitled.

SHORT-HAUL: A term used to define flights or traffic which travel over a relatively short distance as opposed to those which travel over a long distance. Normally, short-haul passengers arrive at the airport of origin later than long-haul passengers, and are accompanied to or met at the airport by fewer persons than long-haul passengers.

STANDBY PASSENGER: A passenger not holding confirmed space but who is on hand at departure time for space that might become available.

TERMINATING PASSENGER: A passenger who has arrived at his destination.

THROUGH PASSENGER: A passenger who arrives and departs on the same flight.

TRANSFER BAGGAGE ROOM: The area to which checked baggage of connecting passengers is delivered for sorting by flights prior to its being dispatched to the aircraft for loading. This may be combined with the outbound baggage room at some locations.

UNIT TERMINAL: One of several functionally complete terminal areas (which may be in the same or several buildings) each of which houses the activities of one or more airlines.

PRELIMINARY DESIGN PROGRAM AND DEVELOPMENT CONSIDERATIONS

Before planning in any form can proceed, the architect must establish a data bank and an ability to retrieve pieces of information in the most rapid manner. This includes all information from participating airlines and all programs on studies that may have been com-

pleted by the airport authority. General economic considerations must be examined and the geographical site location evaluated. The acquisition of the data, the digestion of same, and the request for supplementary information must be made at this time.

The architect must also make inquiries to the governing agency as to the requirements of the Civil Aeronautics Administration and all other government agencies. The architect must further recognize the assistance, advice, and guidance by organizations such as Air Transport Association, Airline Pilots Association, and International Air Transport Association.

The most important single element that the architect must provide for in his design is flexibility, so that all elements of the system may grow as required. In design and planning, the following must have growth capability on an individual basis without jeopardizing the total relationship of the master plan. Parking lots must be capable of growth within any specific area as demands require, and public transportation systems must be capable of individual growth. Curb frontage must grow on an independent basis. Baggage claim areas, check-in areas, gate lounge areas, aircraft positions, the number of aircraft positions—any or all of these elements and the airline operational areas must offer the capability of independent growth to meet the changing demands of the future.

The prime reason for this independence and flexibility relates to the problem of aircraft technology and the fact that the preestablished schedules may change and, as a result, congestion may become a problem at almost any point in the terminal system. These two factors make it mandatory that each element have a built in potential for expansion.

Most of the airports and the terminal structures involved have been based upon a program which is known as a *traffic forecast*. Most of the terminal buildings have been predicated on a "guesstimate" or a series of criteria and assumptions. These criteria and assumptions are further based on the guesstimate of schedule. It therefore follows that the architect would be wrong to design a structure with fixed parameters based on this information. Flexibility must be inherent in each of the elements, yet both good design and economy must be maintained. When all program information has been collected and expansion flexibility has been planned for, the architect must establish a first-stage program based upon the scheduled opening date for the airport. He must then relate this program to an ultimate date of operation. The best method for this is through the use of a computer model simulation.

The computer simulation can be established by examining the maximum number of aircraft movements that air saturation will allow and correlating this with the maximum ground area that may be available for the airport under consideration. This data can now be related back to the terminal building area for all functional disciplines that pertain. The summation of maximums and minimums will now serve as a guide for the master plan of the terminal building area. Since this analysis is extremely complex, the architect should retain specialists in this area of endeavor.

Using the computer simulation as a working tool, the architect can establish a preliminary design concept or concepts and, in addition, preliminary expansion stages for planning can be established. The architect should not take this preliminary work back to the computer at this time. Instead, he must now test and eval-

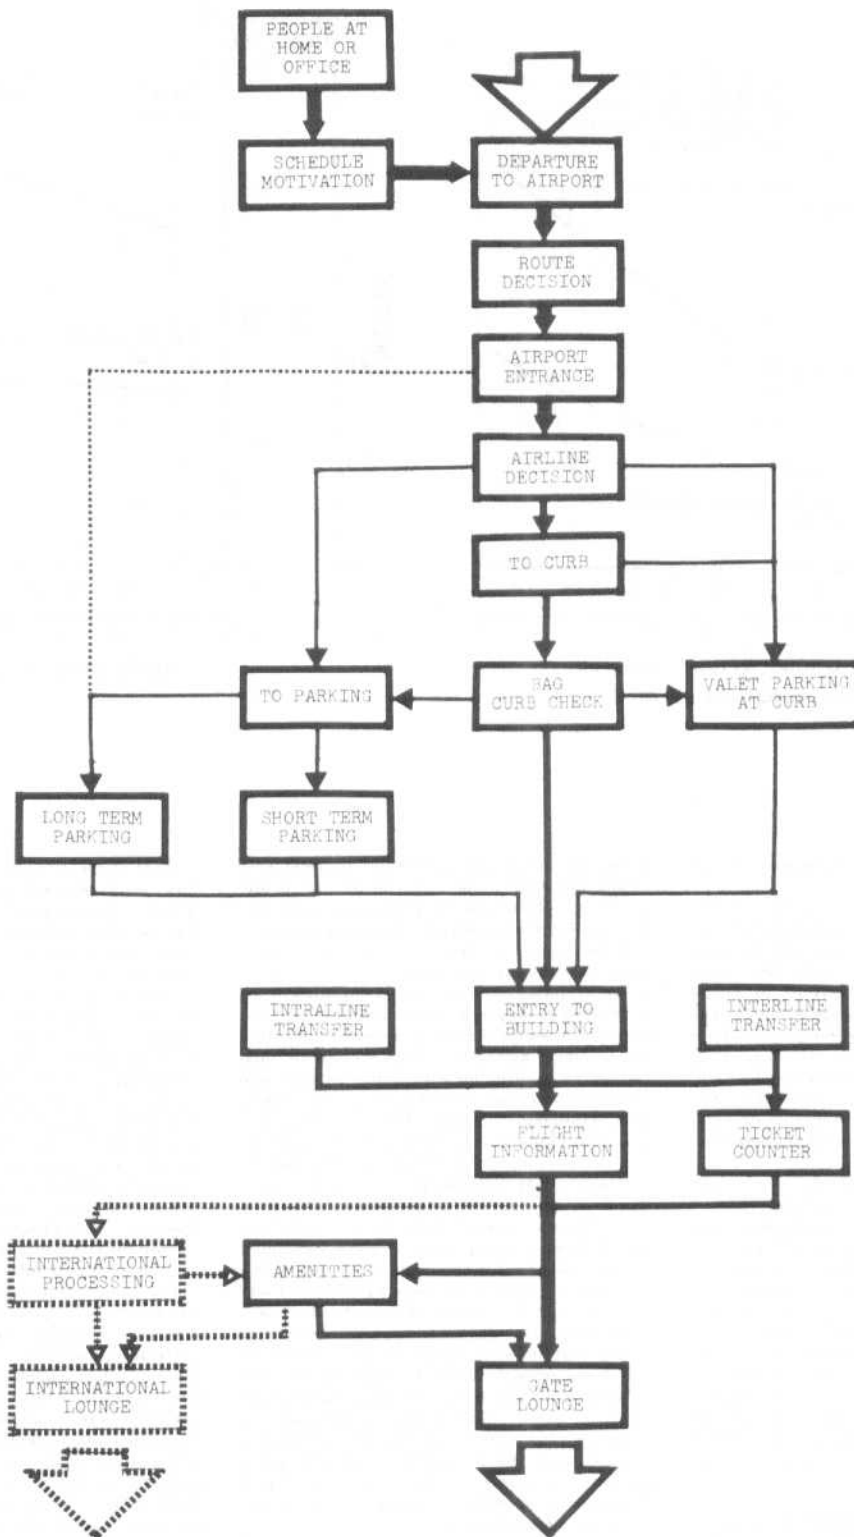

Fig. 11 Enplaning passenger flow.

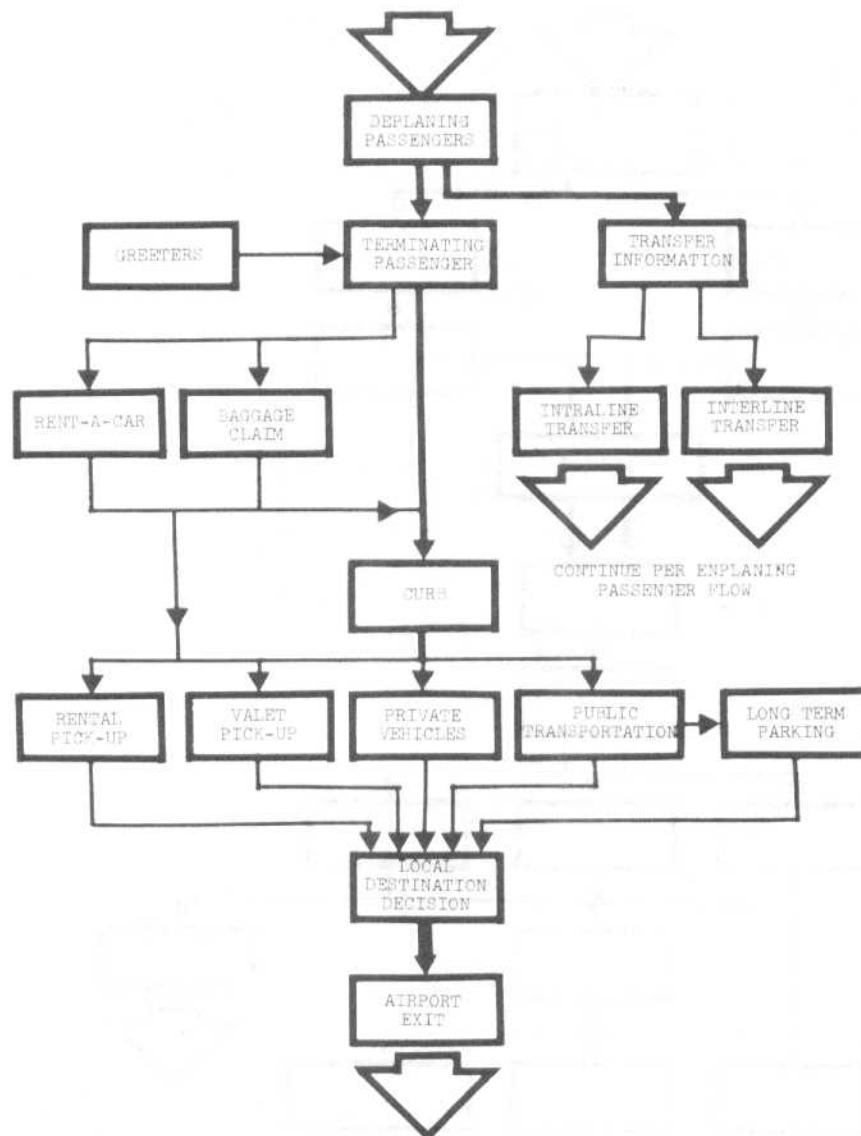

Fig. 12 Domestic deplaning passenger flow.

uate critical conditions that can occur due to changing technology, passenger growth, and expansion, and the computer will allow him to check each discipline of all the functional aspects of the terminal area. This would include all functions within the terminal building, curb-side accessibility, parking requirements (both public and employees'), road access and capabilities, public transportation, etc. Either computer simulation or analytical methods will establish time periods of congestion traditionally referred to as "average peak hours." The architect will carefully examine the average peak hour so as to ascertain simple, direct, and logical routes for all passengers, including their baggage and their vehicular transportation. He should then take these movements to the computer for analysis.

For example, assume that in the design of the terminal, average peak-hour traffic prob-

lems relate to a time span of 11 A.M. and 2 P.M. for arriving passenger flights. What will happen if, operating on the present city relationships, new aircraft traveling at considerably greater speeds become operational at this airport? It is very possible that the computer simulation will show there is no effect, or, quite the contrary, it may show that the average peaking conditions may double up.

Taking into account the time frame, the architect will be further required to work with each of the airlines to ascertain their method of operation. How do they handle passengers, baggage, cargo, amenities, food service, ramp operations, maintenance, and their own personnel? He will then attempt to provide space utilization compatible with the different users. He will also establish those space needs required by the FAA, the airport administration, etc.

Another inevitable problem directly related to the terminal building is that of providing parking space for automobiles. The architect must acquire from the operator of the parking area a system of tariffs, including those that will be applied to short-term, long-term, and valet parking. Without the tariff indication, it is impossible to determine the accrual rate of vehicular parking. The accrual rate is the factor that determines the number of parking spaces that will be required. Any change in the tariff or relationships of tariffs will change the accrual rate and therefore will change the parking space requirements.

As an additional factor, the architect must consider employee parking and the congestion that occurs during the shift changes. It therefore becomes necessary for the architect to ascertain the general character of employment practices by the airlines involved as it relates

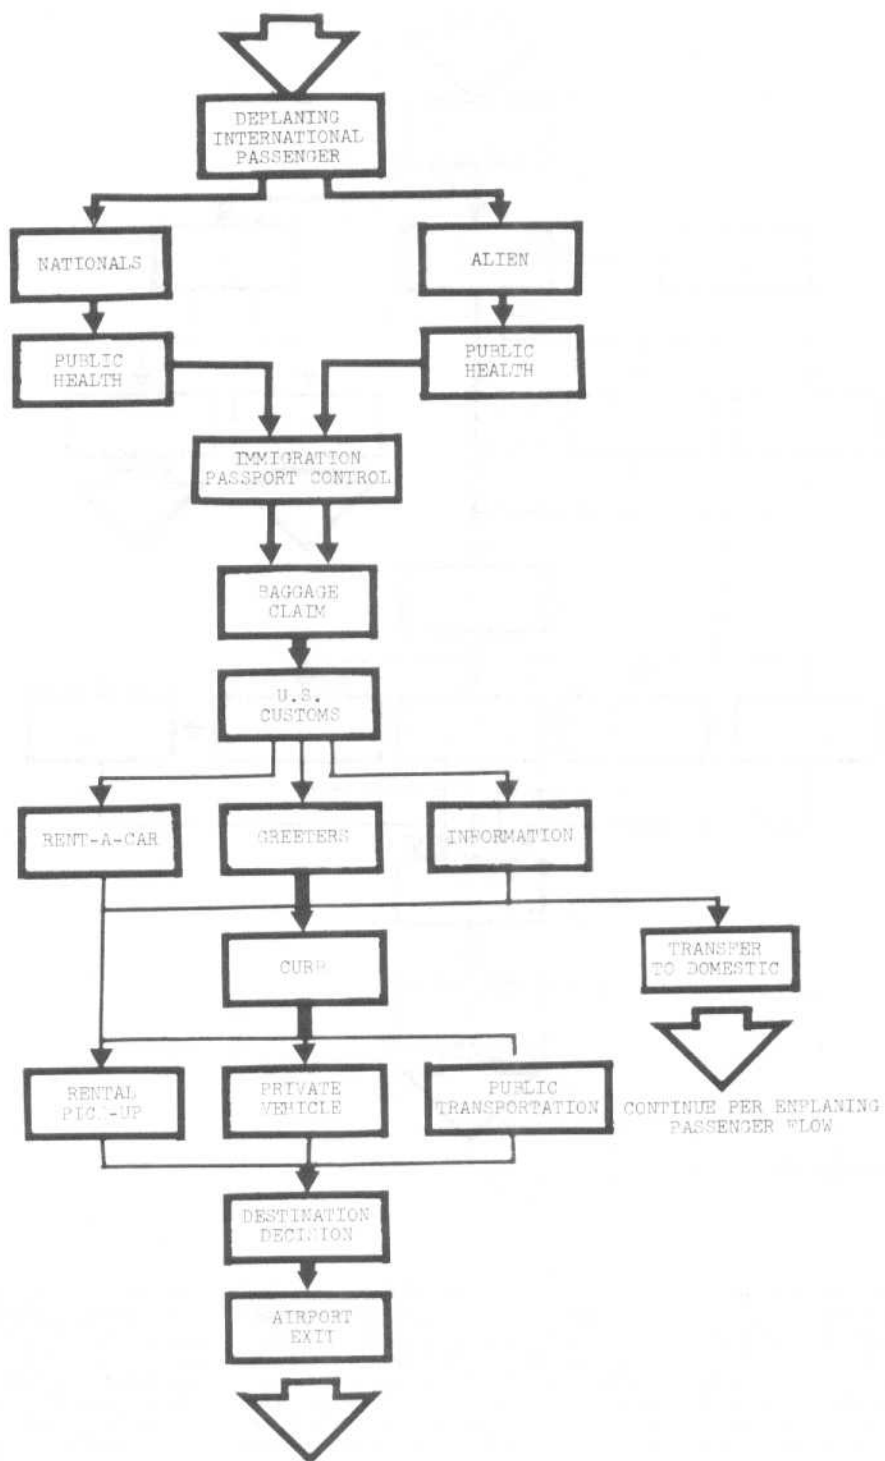

Fig. 13 International deplaning passenger flow.

Fig. 14 Enplaning baggage.

to the schedule of time. Care must be exercised in developing access for employees to the terminal building.

In developing the passenger terminal, the architect must recognize in the early phases of planning that the new wide-body type of aircraft carries vast amounts of cargo. The economics of the new aircraft require that a sizable portion of its cargo-carrying capacity be utilized in the transportation of passengers.

Therefore the passenger terminal, if it is to serve in the best interests of the airlines and their equipment, must have the capacity to store cargo for loading into passenger aircraft. This is true for all types and sizes of passenger terminal and will tend to hold for the small terminal as well as major terminals. For with the greater use of the wide-bodied aircraft, this is becoming standard practice.

Since the passenger terminal is the transfer point between land and air, consideration must be given to the geometries of the aircraft apron. It should afford a great degree of flexibility to include larger aircraft, aircraft mix (different types of aircraft), space required for ground equipment, the storage of cargo, and the techniques for loading people from the building to aircraft.

Any passenger terminal system will rely

heavily upon the ability of the public to secure information. It is therefore incumbent upon the architect to give consideration as early as possible to the nature and types of information systems that will be made available to the general public, so as to guide them to their desired locations.

Early planning must take into account fire safety and access to the structure as well as the probabilities of insurance premiums. The fire hazards relating to the terminal structure can be most readily identified as aircraft, fueling operations on the aircraft apron, public area hazards, baggage room areas, and cargo storage areas.

It is not unusual in smaller terminals for secondary functions of the airline to be incorporated into the terminal building. These may fall into categories such as in-flight feeding, line maintenance, and general office use.

The designer of the terminal building must at an early date include significant analyses of engineering considerations, as this will involve boiler plants, air conditioning, electrical distribution, communications systems, waste removal, and maintenance areas. Any mechanical system that is utilized must of necessity have an alternate or redundant system so that reliability of operation is guaranteed at the airport.

GENERAL DESIGN CONSIDERATIONS

Figure 17 attempts to illustrate some of the devices and systems which are available to the designer. The selection of the appropriate combination of elements will be predicated upon the carrier who will utilize same, the combination of carriers, the geographical site size and layout, and the economic considerations related to the total system development. All these techniques are constantly being improved and updated.

Design Solutions for Passenger Terminals

It is well to examine many of the historic techniques that have been utilized in the development of passenger terminals, as much can be gained therefrom.

Consolidated Passenger Terminal In this illustration, the designer can examine the technique of relating several airlines to a consolidated single structure. This structure initially provides a simple transfer stage for ground vehicles and air vehicles. The epitome of this and the most efficient in operation would be a simple airstrip with no more than a few aircraft positions and occasional aircraft scheduled.

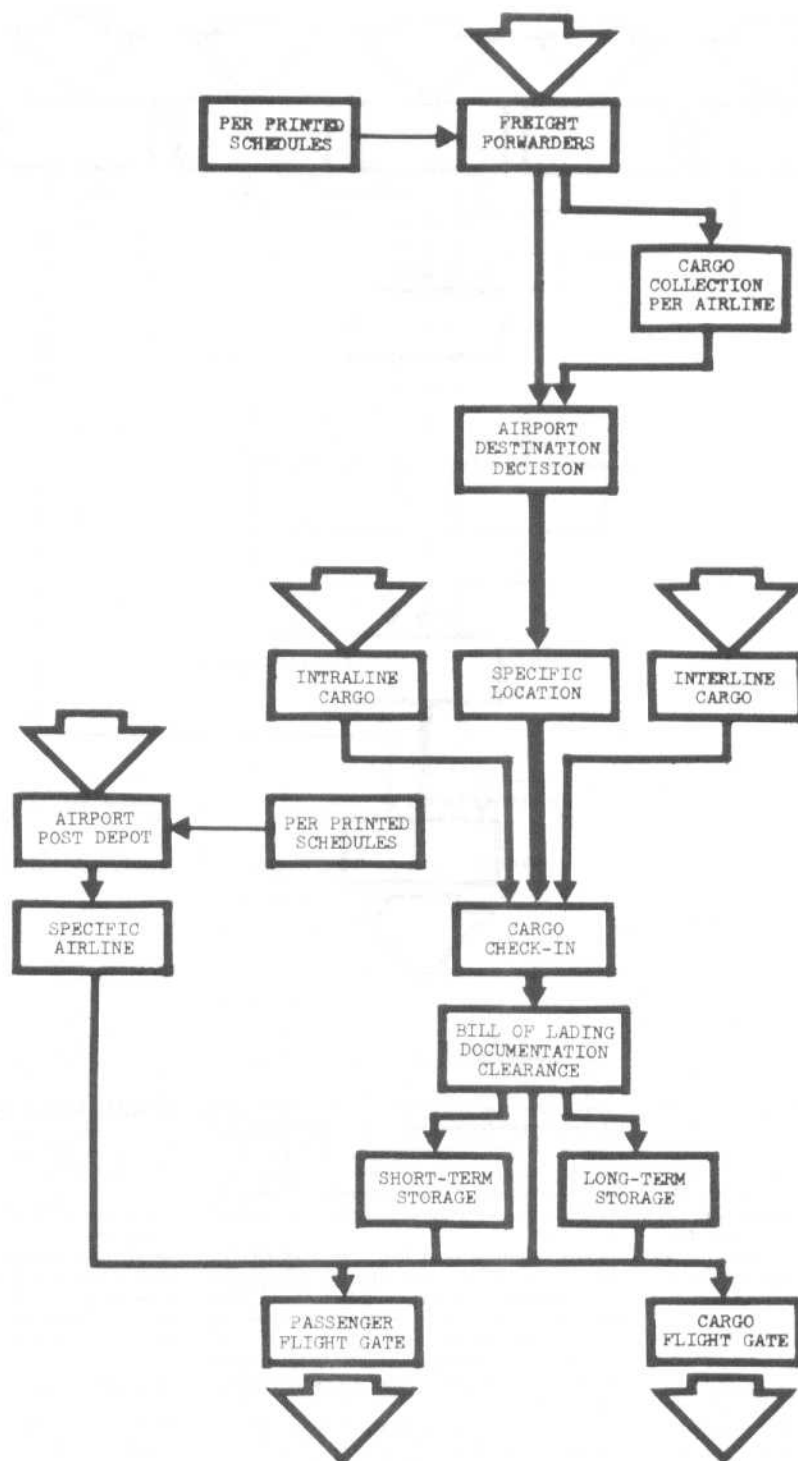

Fig. 15 Enplaning cargo.

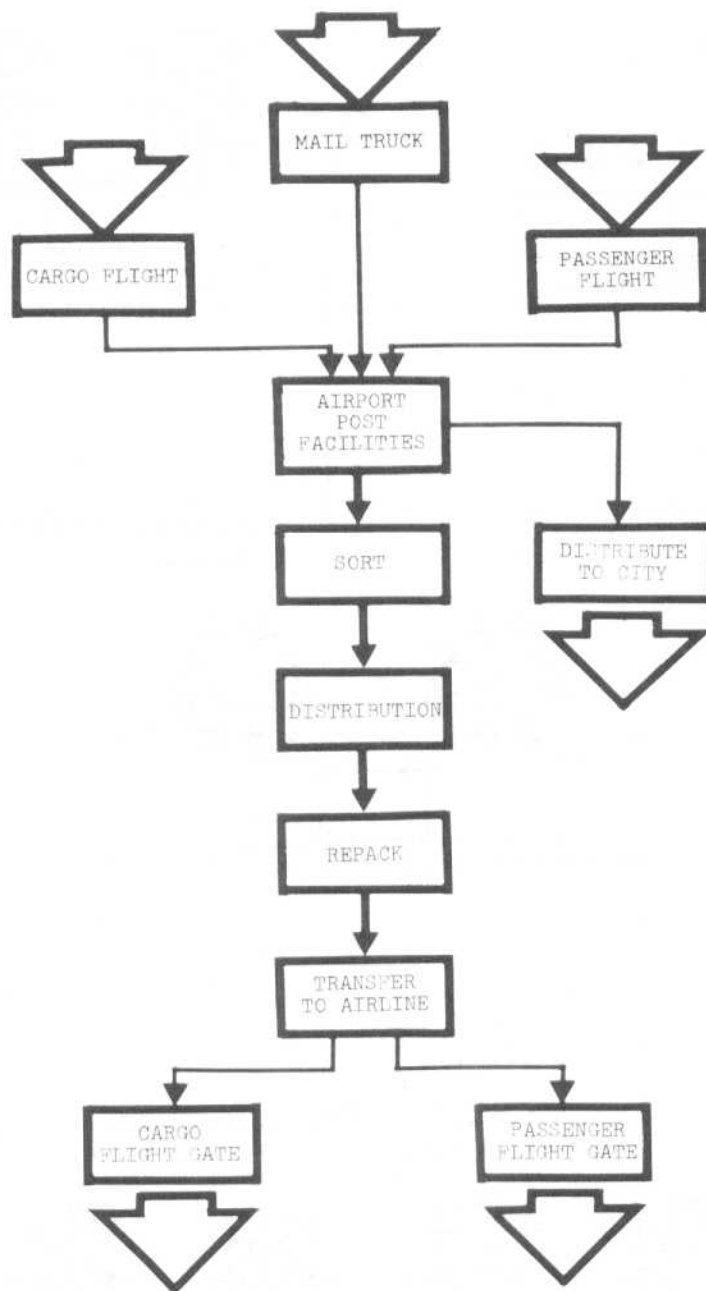

Fig. 16 Mail cargo.

The effective use of the consolidated terminal can best be measured by convenience to passengers and efficiency of operation for the airline. Major terminal complexes invariably are multiples of this small, consolidated group.

Finger Terminal (Consolidated)

Satellite Terminal (Consolidated) In these two illustrations the designer can see the evolution of a finger terminal and a satellite terminal arrangement as merely an expansion of a concept. Now the convenience to the passengers has been questioned and the increased number of aircraft positions has been related as

closely as possible to the consolidated function. The evolution of these two concepts has introduced many varied problems with the single terminal. The problems are related to ground transportation needs, access to the building, prolonged walking distances, grave limitations on the aircraft apron, and the fact that all functional requirements for the airlines are totally constrained because of the physical arrangement.

Finger Terminals (Decentralized)

Satellite Terminals (Decentralized) By looking at the next two illustrations, the designer can see that decentralization offers the possibility

of lessening the constraint for the individual airlines and allowing each airline to operate within its own building, but it also causes difficulties to the public in terms of rapid communications for the proper selection of a desired location. The decentralization causes further problems of interline transfers. While it also permits some advantages of more aircraft apron space, it does involve great demands upon ground vehicle transportation, problems which may possibly be solved by the use of a rapid transit system.

Drive to Gate The next illustration shows a drive-to-the-gate concept which is really the simplest form of terminal, relating back to the

TABLE 1 Airline Statistical Data Requirements

1. Estimated enplaning and deplaning traffic:
Figures on enplaning and deplaning passengers should be given separately.
 - a. Passengers — total number per year
Passengers — average day, peak month
Passengers — peak hour and time
Passenger characteristic (business, vacation, student)
 - b. Interline passengers
 - c. Intraline passengers
 - d. Originating passengers
 - e. Air freight cargo — total tons
 - f. Mail — total tons
 - g. Baggage — total number per year
Baggage — average day, peak month
2. Projected flight schedule:
 - a. City pairs
 - b. Originating and terminating
 - c. Time frame
 - d. Aircraft type
3. Aircraft:
 - a. Number of gate positions
 - b. Number and type of aircraft for gate size design
 - c. Aircraft parking attitude
4. Terminal building spaces:
 - a. Gate lounge — number and sizes
 - b. Baggage claim type and size
 - c. Amenities area
 - d. Operational facilities — type and sizes
 - e. Central ticketing facilities
5. Automobile parking requirements (airline experience):
 - a. Public
 - b. Valet
 - c. Taxis
 - d. Limousines
 - e. Car rental
 - f. Employees

early consolidated terminal approach with a minimum of passenger constraints. The success of this terminal approach is dependent upon a highly sophisticated information system and a ground vehicle connection between gates or related groups of gate locations.

Mobile Lounge The mobile lounge system as a concept provides a consolidated terminal with remote parking of aircraft, and this as a system can operate efficiently and function properly as long as the gate lounges are operative (this precludes allowing drivers of the lounges the right to strike against the operator of the airport).

It poses problems in ground control on the air side of the terminal building and requires additional personnel for its total operation.

These illustrations show schematically the design concepts that are in use in present-day airports. They also point out their own efficiencies and their specific resultant problems, none of which are insurmountable. It is apparent that these basic concepts take many varied shapes and forms in present-day use and that combinations of concepts are employed. It is also apparent that substitute methods of ground transportation are in use for movement within the terminal area and for remote aircraft parking areas. However, no matter what combination of systems is designed, to reach a desired solution, it must be tested and checked for the specific requirements of any given airport for its present use and for its future growth.

AIRLINE REQUIREMENTS

The architect will carefully ascertain from the individual carriers their specific needs. This information should be correlated to the year of operations, the anticipated level of passenger and cargo, operational growth, the potential of changing route structures, and an initial and future projected flight schedule. Table 1 lists the basic data information that is required from the airlines. There are many additional technical information items which are not listed here, but the designer will determine these by inference.

Each airline demands a distinctive visual character that will make it readily identifiable to the public. All too frequently the architect tends to dismiss this requirement. The careful integration of individual airline identification in a total building design will assist the passenger. An airline will retain many professional consultants in attempting to carry a corporate image systemwide, and it will spend considerable sums of money in order to achieve this.

Undoubtedly, not all corporate identity systems are in good taste. However one should not dismiss the very special effort to achieve a simple visual image that the airlines attempt to achieve. Design judgment at this point is of paramount importance.

AIRCRAFT PARKING SYSTEMS

The placement of aircraft on the aircraft apron may be divided into two categories: push-out

operations and power-out operations. The architect should determine the general technique that the airlines will utilize. The system they select will have a great effect on the aircraft apron area as well as the passenger loading system that can be utilized.

Power-out operations will involve special design considerations with regard to the wall surfaces of terminal buildings and they will require greater apron area. They will also call for blast protection in the operational areas of the terminal. This method of operation will generally mean that fewer ground personnel and less equipment are required.

The push-out operation requires the use of expensive tractors and personnel to move the aircraft out of its gate position before it powers away from the terminal area. The push-out operation does offer the advantage of requiring less apron area. It also requires less square footage at the terminal building because of a reduced linear length.

Included in the data sheets is general information related to the major types of aircraft presently in operation and some information related to future aircraft (Figs. 18 to 21).

PASSENGER LOADING METHODS

The passenger is most vocal about the technique that an airline uses for loading the aircraft. He responds rapidly to climatic conditions and will inevitably express his distress to the airport authority and the airline. Many sys-

AIRPORTS AND TERMINALS

- (e) This diagram demonstrates a fixed jet way of short length and with a small amount of telescoping capability. This jetway also has the capability of making some adjustments in sill height. The gate position can only be a power-in, push-out condition.

- (f) This method, which is used in some present-day airports, consists of a train of carts designed to carry passengers or it may consist of the use of buses to deliver the passengers to a remote aircraft parking position. The terminal building can be either a one-level or two-level structure.

- (g) This method is known as the Mobil-lounge and consists of an elaborately furnished bus with a scissor lift and a telescoping front to achieve the interface between both the aircraft and the terminal building. The aircraft is parked at a remote position from the terminal building.

- (h) This method is used for the wide-bodied aircraft and will accept the B-747, the DC-10 and the L-1011. The two main corridors are fixed in their location, however, the four short jetways have telescoping capability in order to achieve the interface with the aircraft. The gate position requires a power-in, push-out condition.

- (i) This method is also used for the wide-bodied aircraft and will accept all three aircrafts as listed above. It is based upon the concept of a fixed corridor for access to the front two passenger doors and a cantilevered jet way over the wing to reach the back door. Here again, the gate position requires a power-in, push-out condition.

Fig. 22 (cont.) Typical loading methods.

Fig. 23 Typical gate lounge.

terminal facilities where there can be many check-in points and more than one baggage makeup space, a system can comprise fully automated cars or pallets that move bags to many destinations. This type of sophisticated system is costly and, in order to justify its use, it should be considered as a total system of all baggage movement, from aircraft to passenger and from passenger to aircraft.

The acceptance of baggage from the originating passenger at the terminal is complicated by the acceptance of interline and intraline baggage for the transferring passengers. A large number of employees, for the amount of baggage handled, are utilized in interline transfers. Their route of travel by vehicle is frequently time-consuming. The transferred baggage is processed in the same backup area as the originating and terminating baggage, therefore space must be allowed in order to accom-

plish this handling. The volume of bags that is to be transferred and processed must be determined in cooperation with the airline user. The precise system used and its building space must have the capability of expansion from the initial operational level.

The selection of the correct baggage system must also be correlated to the reverse flow of baggage from aircraft to baggage claim. The baggage claim system, by its very nature, produces an acute problem of baggage handling. The terminating passenger from an arriving flight expects to claim his baggage within a short period of time. A peaking condition occurs when a combination of flights arrives within the same time frame. In contrast, the originating passengers will generally arrive at the airport over an extended period of time, therefore dispersing the handling of baggage over the same time period.

As larger aircraft, such as the 747, are utilized in greater numbers, the peaking conditions increase and decentralization of the baggage claim system becomes more desirable for the sake of passenger convenience and the elimination of congestion.

Baggage claim devices can involve many different shapes, forms, and methods of mechanical or manual handling of baggage. Figure 24 demonstrates the basic concepts that are available. The designer can see from these illustrations that the basic general technique is to produce a great display of linear feet of frontage so that passengers can readily identify their bags and claim same.

The interface between the aircraft and the claim area is still generally accomplished by towing the baggage to the terminal building, where a manual operation accomplishes the placement of baggage on the claiming device.

The ability to retrieve bags from the aircraft and transfer same to the terminal baggage handling system is a key element in rapid and efficient baggage dispersal.

The design of an automated system to transfer the baggage modules to the building system is technically feasible. This would eliminate the towing operation and provide a faster method of producing the baggage at the claim area. It would also mean that the baggage could be claimed in many different locations. However, this will depend upon the airline's required time frame, passenger convenience, and financial capabilities.

Baggage rooms must be handled with special caution to make sure that sufficient quantities of fresh air are provided if gasoline power tractors are used. Sprinkler protection must be provided and careful fire cutoff must be made between the terminal proper and baggage areas. Doors leading from the baggage room to the outside should be automated and must use rapid-acting equipment. However, it is important to provide, on all doors, safety edges which will prevent closure should an obstacle be in the way. The design concept must incorporate the capability of future expansion, and preferably this should be accomplished without disturbing the existing claiming facilities.

Area Considerations for Baggage Systems

Enplaning Baggage As indicated in the flow diagram (Fig. 14), baggage may be received from three possible sources:

1. *Curbside check-in.* This area must provide convenience of tagging and usually some mechanical conveyance back to a central bag room.

2. *Counter check-in.* This will coincide with the usual ticket counter in the main terminal area. It is customary to provide mechanization from an area directly in the back of the ticket counter to the central baggage room.

3. *Gate check-in.* In small quantities, bags are received at the gate. Bags must be checked in at this point because many passengers mistakenly believe that their suitcases will be accepted for storage in the passenger portion of the plane. A significant number of airline passengers frequently use carry-on suitcases, but unless such luggage can be stored below the seat and out of aisle space, it must be carried in the baggage compartment.

4. *Transfer baggage.* Additional bags will be received at a convenient location adjacent to the baggage room for transfer from other airlines or the same carrier. All baggage rooms which utilize mechanized equipment must be provided with sufficient room for manual handling in the event that service requirements cause a shutdown.

Deplaning Baggage For baggage claim areas, a simple square foot calculation cannot be used to determine the desired area, for there are too many variables that influence establishment of the proper layout. The basic terminal building concept will have a great influence on the baggage claim design. A terminal building which consolidates all the airlines into one claim area establishes a different set of parameters than does a terminal building concept where decentralization of airlines separates the baggage claims for each airline. In some decentralized concepts, airlines are now developing more than one claim area for each traffic level. A terminal building which processes international arrivals requires another set of parameters for the establishment of the claim area.

In order to size a baggage claim area, the architect must have the following information: the number of passengers and the amount of baggage that will be claimed within the peak condition, the type of claiming device and its physical size, its capacity, and its linear feet of frontage. Care should be taken to determine the actual working capacity of the claiming device and not the theoretical capacity as advertised by manufacturers. The architect should also determine the desired type of operation and degree of security required by either the airline or the authority. With the correlation of this material, the architect can now start to size the claim area. For an international arrivals system, the architect should allow additional space for the queuing of passengers between the claim device and the customs inspection system.

GENERAL CONSIDERATIONS

Needless to say, passengers who may be carrying baggage should be offered such conveniences of design as automated doors, sufficiently wide escalators, moving sidewalks, and similar devices. At all times the analysis of traffic flow, volume of passengers, and direction of movement should be carefully considered.

Air traffic passengers rapidly cross international boundaries, and language problems must be anticipated. The International Air Transport Association has given serious consideration to the language problem and has attempted to develop a series of glyphs which can frequently be used in lieu of bilingual messages.

Telephone communication is a necessary and important element in the passenger terminal. In some instances this will require a telephone communication center with bilingual operators.

The terminal must also provide amenities for the traveling public. These may include any of the following list and such other items as may be determined by a particular locale:

Bank	Newsstand ¹
Barber shop	Observation deck
Camera shop	Parcel lockers ¹
Candy store	Restaurant and
Car rental agencies ¹	supplementary
Cocktail lounge	eating facilities ¹
Drug store	Rest room facilities ¹
Duty free shops	Shoe shine
Employee snack bar	Showers/dressing rooms
and cafeteria ¹	Teenage lounge
Flower shop	Telegraph (desk, phones,
Gift shop	or both) ¹
Haberdashery	Telephones ¹
Hotel	Television lounge
Insurance vending ¹	Valet
Money exchange	Women's wear

In addition to the amenities, consideration should be given to traveler's aid in large installations and nursery facilities adjacent to the women's lounge in the main portion of the facility. Medical and first-aid facilities should be included in the passenger terminal if they are not provided elsewhere in the airport.

An internal telephone system may be required between the airlines, the operating authority, and/or police authorities. The size of the terminal building and the complex needs of each user should receive consideration when planning the telephone system.

¹ Considered essential by airline operators.

CURB FRONTAGE UTILIZATION

When designed correctly, curb frontage at the face of the terminal building will function properly for a very high percentage of the time. The curb frontage can be the failure point for the entire terminal operation. It can cause confusion, congestion, missed flights by enplaning passengers, and become a safety hazard to pedestrians if they must cross the road system.

The architect must devote considerable time and effort to designing the curbside frontage and the road system to it. Present design trends and concepts have separated the enplaning and deplaning road systems, but very few have eliminated pedestrian traffic across these roads. (See Figs. 25 and 26.)

In the design of the curb frontage, the architect must consider all the forms of vehicular movement, such as private passenger vehicles, valet-driven cars, rental cars, taxis, and public transportation (especially buses).

To determine the quantity of curb frontage, the following factors and assumptions must be considered:

1. All vehicles will require approximately 35 lin ft at the curb. This is a realistic interpretation of the indiscriminate manner in which vehicles tend to be parked.

2. The average time required at the curb for passenger vehicles should be surveyed for passengers by type of vehicle.

3. Duration time for valet parking will exceed the standard for passenger cars in order to provide time for an attendant to queue the vehicle prior to its being parked and so as not to impose a penalty on the need for curb frontage. The total of parking queuing time is estimated at five minutes.

4. In order to compensate for heavy congestion periods resulting from holidays, delays, etc., occurring 12 times or more per year, it is recommended that the working frontage be increased by 30 percent beyond normal calculations.

5. The system of curb frontage must be allowed for in the total master plan and thereby its expansion from the initial operation.

6. Under no circumstances should the prime arterial circulation road be used as curb frontage. Rather, a spur from the main road network should be extended to the curb frontage.

7. The curb frontage should be divided into active and passive curb. The passive curb is utilized for valet queuing or other long-term uses such as bus connections.

8. It is necessary to determine the average peak vehicular traffic for both enplaning and deplaning passengers. A graph or summation sheet should be prepared. It is helpful if this is done by 20-minute increments, and the cumulative total peaking can be determined if there is no separation of enplaning and deplaning traffic. In the event that the enplaning and deplaning functions are totally separated, the summation peak will result in isolating the time frame for the maximum parking demand as well as vehicle peak of appropriate road. A typical example of a chart is shown and the formula to be utilized is demonstrated on p. 952.

Duration Schedule in Minutes (if no survey data is available)

	Enplaning	Deplaning
Private cars	2	3
Valet cars at curb	3	3
Valet queuing	5	
Rental cars	3	3
Taxis	5	5

- (a) The baggage is transported from the aircraft to the claiming device by a cart and is then off-loaded manually by an attendant.

- (b) DIVERTER In this system the baggage is placed on a conveyor at one end. A diverter moves back and forth along the conveyor and disperses the baggage onto the claiming device.

- (c) CAROUSEL A conveyor, from underneath or from above, delivers the baggage to a rotating carousel.

- (d) RACE TRACK A conveyor from underneath or from above, delivers the baggage to a continuously circulating conveyor, the length of which will depend upon the terminal layout.

Fig. 24 Baggage claim systems.

- (e) POD The baggage pod is removed from the aircraft and delivered to the claim area. The passengers **remove** their baggage from the pod.

- (f) AMOEBA This system is an extension of the race track system. The only difference being that the baggage is manually loaded directly onto the conveyor by an attendant behind a wall and out of view from the passengers.

- (g) AUTOMATED This system consists of carts that are operated by a computer system. The passenger inserts his claim ticket into a call box at a desired location, the cart then delivers the baggage at that location.

AIRPORTS AND TERMINALS

This chart is only an example and does not pertain to any specific airport, airline, or passenger count.

Fig. 26 Composite enplaning and deplaning working volumes at curb frontage.

TERMINAL AREA CONCEPTS

The following terminal concepts should be considered in the development of the terminal area plan. Sketches of the various concepts are shown in Figs. 1 through 4. Many airports have combined one or more terminal types.

a. Simple Terminal Concept The simple terminal consists of a single common waiting and ticketing area with exits leading to the aircraft parking apron. It is adaptable to airports with low airline activity which will usually have an apron providing close-in parking for three to six commercial transport aircraft. A simple terminal will normally consist of a single-level structure with two to four gates where access to aircraft is afforded by a walk across the aircraft parking apron. The layout of the simple terminal should take into account the possibility of pier or linear extensions for terminal expansion.

b. Pier Concept The pier concept (Fig. 1) has an interface with aircraft along piers extending from the main terminal area. In the pier concept, aircraft are usually arranged around the axis of the pier in a parallel or perpendicular parked relationship. Each pier has a row of aircraft gate positions on both sides, with the passenger right-of-way or concourse running along the axis of the pier which serves as the circulation space for enplaning and deplaning passengers. Access to the terminal area is at the base of the connector (pier). If two or more piers are employed, the spacing between the two piers must provide for maneuvering of aircraft on one or two apron taxiways. When each pier serves a large number

of gates, and the probability exists that two or more aircraft may frequently be taxiing between two piers and will be in conflict with one another, then two taxiways are advisable. Also, access from this taxiway system by two or more aircraft may require two apron-edge taxiways to avoid delays.

c. Satellite Concept The satellite concept (Fig. 2) consists of a building, surrounded by aircraft, which is separated from the terminal and is usually reached by means of a surface, underground, or above-grade connector. The aircraft are normally parked in radial or parallel positions around the satellite, which can have common or separate departure lounges. Since enplaning and deplaning of the aircraft are accomplished from a common area, mechanical systems may be employed to carry passengers and baggage between the terminal and satellite.

d. Linear Concept In the linear concept (Fig. 3), aircraft are parked along the face of the terminal building. Concourses connect the various terminal functions with the aircraft gate positions. This concept offers ease of access and relatively short walking distances if passengers are delivered to a point near gate departure by vehicular circulation systems. Expansion may be accomplished by linear extension of an existing structure or by developing two or more linear-terminal units with connectors.

e. Transporter Concept Aircraft and aircraft-servicing functions in the transporter concept (Fig. 4) are remotely located from the terminal. The connection to the terminal is provided by vehicular transport for enplaning and deplaning passengers. The characteristics of the transporter concept include flexibility in providing additional aircraft parking positions to accommodate increases

in schedules for aircraft size, capability to maneuver an aircraft in and out of a parking position under its own power, separation of aircraft servicing activities from the terminal, and reduced walking distances for the passenger.

CONCEPT COMBINATIONS AND VARIATIONS

Combinations of concepts and variations are a result of changing conditions experienced from the initial conception of the airport throughout its lifespan. An airport may have many types of passenger activity, varying from originating and terminating passengers using the full range of terminal services to passengers using limited services on commuter flights. Each requires a concept that differs considerably from the other. In time, the proportion of traffic handled by these flights may change, necessitating modification or expansion of the facilities. Growth of aircraft size or a new combination of aircraft types serving the same airport will affect the type of concept. In the same way, physical limitations of the site may cause a pure conceptual form to be modified by additions or combinations of other concepts.

Combined concepts acquire certain of the advantages and disadvantages of each basic concept. A combination of concept types can be advantageous where more costly modifications would be necessary to maintain the original concept. For example, an airline might be suitably accommodated within an existing transporter concept terminal while an addition is needed for a commuter operation with rapid turnovers which would be best served by a linear concept extension. In this event, combined concepts would be desirable. In conclusion, the appearance of concept variations and combinations in a total apron-terminal plan may reflect an evolving situation in which altering needs or growth have dictated the use of different concepts.

the Navy, Washington, D.C.

This diagram demonstrates schematically the design concept of curbside off-loading for private vehicles, taxis, limos, buses, and valet queuing space. The valet queuing space is separated from the active curb frontage because the duration time is much greater for the valet car than for other vehicles. The number of through lanes will depend upon the amount of traffic that will pass during the peak condition.

Fig. 6 Curb frontage diagram.

Working Curb Footage Requirement Schedule

$$\begin{array}{l}
 35 \text{ ft} + \text{units} \times \text{time duration} \times 35 \text{ ft} \\
 \text{(no. of cars)} \quad \text{at curb, min.} \\
 \quad \quad \quad 20 \text{ min.} \\
 \text{Example: Assume 40 private cars on the} \\
 \text{enplaning road.} \\
 35 + 40 \times \frac{2}{20} \times 35 = 35 + 40 \times 0.1 \times 35 \\
 = 35 + 140 \\
 = 175 \text{ ft of curb required}
 \end{array}$$

Note: After all vehicle types are calculated, increase total by 30 percent.

PARKING REQUIREMENTS

The revenue that is collected from the public parking areas of an airport is one of the airport authority's largest sources of income. Therefore, the architect must devote attention to the different types of parking and how they function as well as to the amount of parking required as based upon the accrual rate (turn-over rate).

The different types of parking are short-term (metered parking), medium-term (one or two days), long-term parking, valet parking, and rent-a-car parking. Each parking area will require a separate system for collecting revenues in an economical and rapid manner. This should be accomplished without requiring policing.

It is possible to establish a formula for determining the number of parking spaces required, but this is complex and unwieldy as it is based upon the passenger traffic and rates. In addition, each airline and especially each airport has a completely different route structure, and each community has a completely different transportation environment. Therefore computer analysis is recommended.

The route structure will affect the parking requirements because the accrual rate will vary from airline to airline. For example, assume airline A and airline B have the same passenger count per day. Airline A's route structure is such that the majority of its passengers return within one day's time but, in

contrast, the majority of airline B's passengers return in two or three days' time. Therefore, it seems obvious that airline B will have a larger parking requirement. However, now the transportation environment must be examined. What percentage of airline B's passengers will leave a car parked at the airport for two or three days in a public parking area? Or is there enough money within the community that these passengers will use the valet parking?

The revenue rate for each type of parking is also an important consideration in developing the total requirement. As the rates change in relation to duration of parking, so will the parking requirements. Therefore, when possible, the rates should be established at an early date so that the parking space requirement can be determined. Planning must include future adjustments for changing rates.

Every airport has an inordinately large number of airline employees who also require parking space. The architect must devote attention to this phase of the parking requirement. Care should be taken to ensure that employees do not take the parking spaces designated for the public. An understanding of the shift schedule, the number of employees involved, and the amount of time that is required to complete a shift is necessary.

The basic parking layout for both public and employees is no different from that for normal parking; however, extensive consideration should be given to all vehicular movement requirements to the parking area, around the parking area, and from the parking area, so that congestion is avoided. Consideration should also be given to control of pedestrian safety and vandalism within the parking areas.

INFORMATION SYSTEMS

Public information systems, unfortunately, tend to become an afterthought of the prime airline information system that the airline user feels he can afford. Little consideration has been devoted to the net effect of space demands in presenting accurate updated information to the traveling public.

There is no reason why the traveling public should arrive at an airport when no aircraft is available for departure. There is no reason for visitors to the airport, expecting to meet people, to arrive at the airport only to find that there will be considerable delay in the arrival of the aircraft.

The present technique of information dispersal is to utilize telephone communication between the interested party requesting the flight information and the airline. During periods of airline operational difficulties, telephone communication is often difficult and frequently impossible to achieve.

The best medium presently available for mass public information is television. Although this has not been utilized to date, there are presently many technical alternative methods. Future terminal designs must initially include dispersal of information to the public outside the airport. If this is accomplished, the secondary functions of public information at the terminal will be superior to present-day methods.

Closed-circuit television systems (CRT), dynamic alphanumeric display boards, and manual display boards are available. These systems to a lesser or greater degree can tie into an airline's internal information systems.

The internal nonpublic system is frequently established so as to provide the many disciplines of the airline system with information as to the number of passengers, seat availability, in-flight feeding requirements, cargo complements, etc. It is also possible for the internal system to be directly related to the airline reservation system so as to compare actual condition of operation with preflight planning. This enables an airline, via the use of computers, to establish important levels of information as related to actual operations vs. preflight.

Another information system which is required is a public address and paging system. This plays an important role in last-minute announcements but is frequently excluded from the amenity areas, thereby reducing the system's effective use. Its importance during emergency conditions warrants the cost of installation.

AIRPORT CARGO CENTER AND ITS BUILDINGS

Interrelationships of Facilities

As the air cargo industry grows, the complex on the airport designed to handle air cargo becomes a significant element in airport planning and design. These facilities must provide for the efficient transfer of air cargo between surface transportation and aircraft. For larger airports, the complex may include a number of air carrier cargo facilities or multiple-occupancy buildings.

Design Considerations

The elements that compose the airport cargo center facilities and establish their character, size, and configuration will depend on the level of activity of the air cargo industry in the community served. The architect-engineer should work closely with the air carriers, air freight forwarders, truckers, and airport management to determine what is needed, including any special requirements peculiar to these facilities. The resulting design must satisfy present requirements and provide the flexibility necessary for future expansion. Buildings should be oriented, and land should be available to enable a logical expansion plan.

The air carrier cargo facility is the core of the cargo center, and the emphasis in this article is on that facility. It may be treated as a single building or combination of elements under one roof sufficiently integrated to permit operation as a single entity.

The design program, in the architect's vocabulary, denotes the building user's space requirements. It is one of the basic essentials for a successful solution to the design of any building. Fundamental considerations in developing a program are the elements of the building, the amount of space needed by each element, and the relationships between the spaces.

AIRPORT CARGO CENTER LOCATION

Importance of Site Planning

The complex on the airport specifically designed for the handling of air cargo is one of the major elements on the airport. The airport cargo center must be sited in a location that will contribute to the efficient transfer of cargo between surface and air transport. The selection of an appropriate site is the decision which determines to a large extent the effectiveness of the air cargo operation. The location of the elements of the complex in proper relationship to each other is of equal importance.

Location on the Airport

Four primary considerations dictate the selection of the site on an airport for the cargo complex.

1. Taxi distance from the most used runways should be as short as possible, and yet

there should not be interference with passenger operations.

2. The site should be readily accessible by surface vehicles from the passenger aircraft loading positions for efficient servicing of aircraft carrying both passengers and cargo.

3. The complex should be readily reached from all access roads to the airport to assure noninterference of vehicular traffic with aircraft movement areas.

4. Adequate space should be allowed for expansion of air cargo operations without encroaching on other airport functions, particularly without interfering with the expansion of the passenger terminal.

These four primary considerations indicate the general relationships with other functions and activities. They require extensive study to determine the degree to which they can be met on any individual airport. This study can best be made through the medium of an airport layout plan in which the advantages of possible locations and their effect on other airport facilities and operational activities can be objectively weighed.

Planning Considerations

The general location of the cargo complex having been established, a number of other factors should also be studied prior to adoption of a siting plan.

The arrangement of buildings and associated support facilities is important to satisfactory and efficient use, and it also affects future expansion of individual buildings. Important in this regard is consideration of spacing of buildings for access, vehicular circulation, and fire and safety clearances. Vehicular access and roadways, and parking areas are discussed in detail in the paragraphs that follow. Proper orientation of buildings, with respect to these factors and the prevailing winds, is essential to the functional operation of the buildings. Economical design dictates the need for balance of requirements for paved areas with other considerations discussed heretofore. Good drainage, consistent with driveway, parking, and pedestrian access requirements, is a necessary design consideration.

Noise is a consideration which must not be overlooked. Acoustical control can be achieved through proper landscape planting for sound absorption.

Cargo Center Site Plan

To illustrate the application of functional relationships discussed in this article, a diagrammatic site plan has been developed. Figure 1 indicates the relationships of facilities for a number of air carrier cargo operators, truckers, air freight forwarders, air express (REA), and airport mail facility (AMF).

The site plan orientation on the airport establishes optimum relationships of aircraft parking apron, and access and service roads discussed in the following paragraphs.

Aircraft Parking Aprons

Paved apron requirements for aircraft parking and loading positions adjoining air carrier

cargo facilities are dependent upon the type and size of aircraft used, airline schedules, and the type of materials handling system used. The need for direct access from certain facilities to the passenger loading apron, for access to both combination and all-cargo aircraft aprons for others, and for completely integrated building-apron relationships for certain materials handling systems are all important. Information on space requirements for aircraft apron parking positions can be found in the article dealing with airport design.

Access, Circulation, and Parking

Discussion of ground vehicle movement considerations is presented in general terms.

Roads Access to and egress from the airport cargo complex and circulatory roads within it should be direct and unimpeded. There should be as little interference as possible with airport passenger vehicular traffic. In those cases, where the number and types of trucks using the access roads will cause frequent passenger traffic congestion, separate roads should be designed specifically for truck traffic leading directly to the cargo center. Visitors, passengers, and customers should be provided convenient access from the passenger terminal area.

Truck Parking Parking areas required include those designed to serve the trucker, the customer and visitor, and the employee. Planning of truck parking spaces and maneuvering areas will probably present a difficult problem because of the many variables. Maximum truck sizes vary from state to state. Trucks bringing freight to the cargo center will be of many types and sizes. Parking areas and truck-dock facilities with adequate maneuvering space must be provided for movement of vehicles without creating bottlenecks during peak loading and unloading hours.

Generally, the recommended distance for maneuvering from the loading platform to the nearest obstruction is twice the length of the largest road vehicle expected to use the facility. The Air Transport Association suggests a minimum overall depth of 100 ft for the terminal-truck apron which will allow 75 ft for maneuvering of trucks plus a 25-ft-wide access roadway. Minimum interference distances may in effect be less when tractors with smaller turning radii are used, when the spacing between trailers is increased, or when a sawtoothed loading platform design is used.

Customer and Visitor Parking Those seeking service should have the most direct access possible to the reception areas of individual air carriers, freight forwarders, and other service facilities. These parking spaces may be adjacent to the building in conjunction with the truck parking area. Permanent parking areas should not be located where expansion of buildings is being contemplated.

Employee Parking Sufficient parking should be provided for employees' cars which are generally parked for a period equal to the length of the working day. Since the employee

AIRPORT CARGO FACILITIES

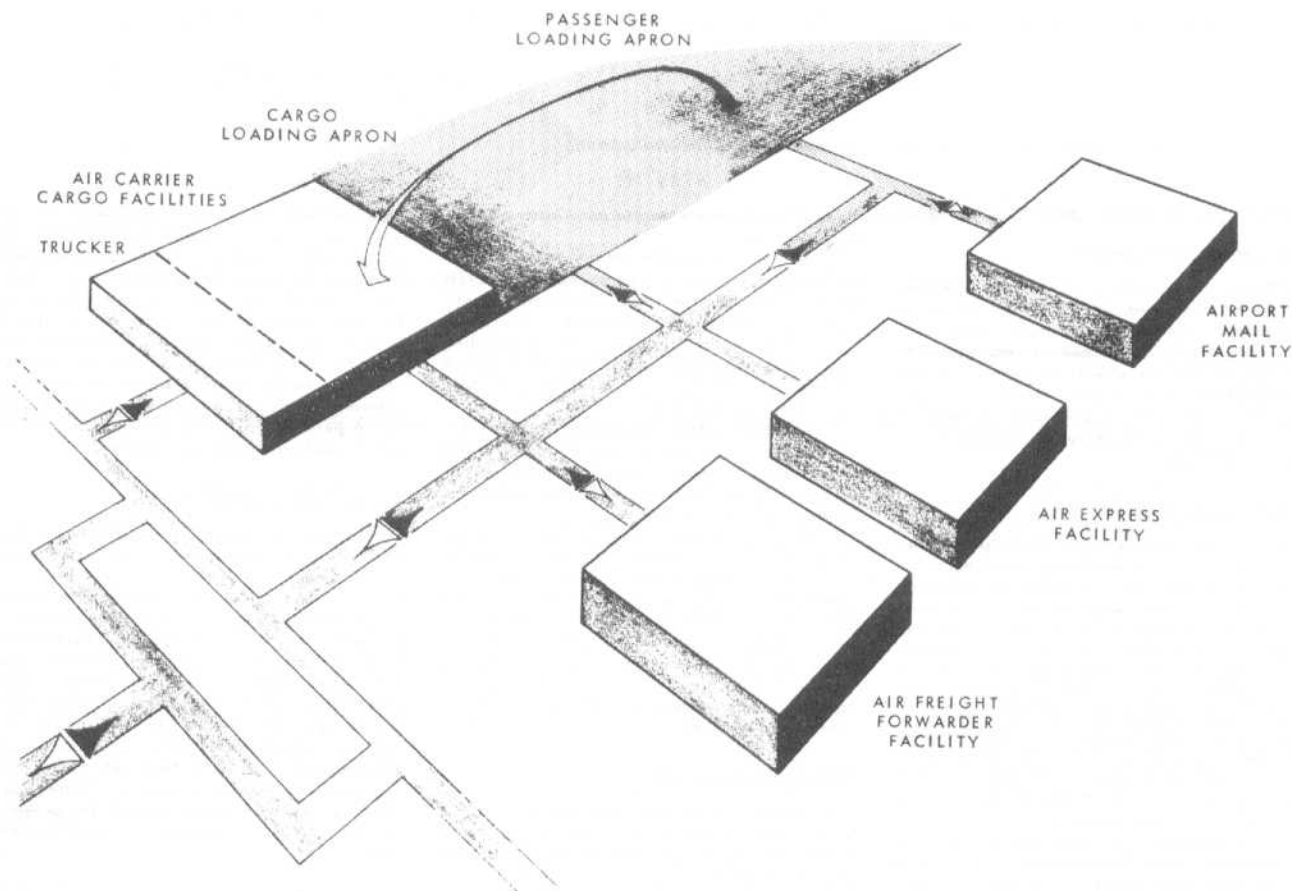

Fig. 1 Relationships of cargo facilities.

does not usually require ready access to his car during this period, it is not necessary to locate the employee parking area directly adjacent to the freight handling facilities. Where the airport is relatively small, an employee parking area common to all operational functions on the airport may be adequate for parking needs. For the larger airport, strategically located parking spaces which may be used by all employees of the airport cargo complex should be considered. There may be just one of these areas planned near the center of activity, or there may be several dependent upon the size and spread of the airport cargo complex. Administrative personnel usually require parking spaces adjacent to the office area because they may have to use their cars frequently during the working day.

AIR CARRIER CARGO BUILDINGS

Elements of the Building

An air carrier cargo building may be planned for single or multiple occupancy. The type of occupancy normally will depend on the potential for air cargo industry growth in the community being served and the volume of business generated by each of the airlines. At airports where there are a number of carriers, each generating only nominal amounts of freight daily, a multiple-occupancy building can provide adequate space to satisfy the needs of all. Single- or double-occupancy buildings with adequate aircraft apron space should be considered for those air carriers that operate all-cargo schedules and handle larger amounts of air freight.

There are four major functional elements to consider in the design of the air carrier cargo building. These are the freight-handling areas, administration area, personnel and customer accommodations, and service facilities. Figure 2 indicates diagrammatically the space relationships for functions within the air carrier cargo facilities. Airport cargo buildings should be designed for planned expansion in both length and depth, where economically feasible, and fixed support facilities so located to avoid interference with such expansion.

Truck Dock Facilities

There must be a sufficient number of truck stations to serve truckers, air freight forwarders, and others for both incoming and outgoing shipments. In addition to truck dock positions, consideration should be given to providing facilities for the airport-to-airport customers who use other than trucks to deliver or pick up small shipments.

The number of truck dock spaces will vary with the airline operation and the community. To determine the optimum number requires detailed analysis of truck arrival in a peak hour, the service time at the dock, and the acceptable waiting time for those experiencing delays.

The minimum number of dock spaces required for incoming trucks can readily be determined. Assume for example a normal "stripping" or unloading rate at each dock space of approximately 5,000 lb per hour. This rate includes time allowed for delays and spotting of vehicles. For an inbound volume from trucks of 90,000 lb of freight and a time allowed for "stripping" vehicles of three hours, the unloading would have to be accomplished

at the rate of 30,000 lb per hour. Thus, there would be a requirement for six truck spaces at the dock for this operation.

The width of each truck station should be a minimum of 12 ft to allow for parking of large vehicles. Building door openings at each station should be a minimum of 10 ft wide by 10 ft high. Extensive open platforms are not recommended because freight left in the open is subject to pilferage and damage from inclement weather. Protection from the weather for freight and personnel during stripping or loading operations should be provided by an overhang canopy of at least 5 ft. Clearance above the top of the parked freight van should be approximately 18 in.

Building floor heights may vary from 44 to 47 in. above grade. There are a number of leveling devices for accommodating truck bed heights ranging from 30 in. for a pickup truck to 50 in. for a large tractor-trailer.

Processing Area

Receiving, sorting, weighing, labeling, and building up of loads for shipment are the major activities in the processing of freight from the truck to the aircraft. There are a number of factors which have a profound effect on total space requirements.

1. *Cargo turnover* is affected by such variables as types of aircraft, frequency of service, time of day of arrivals and departures inbound, outbound, and directional preponderance of cargo.

2. *Density of cargo* accounts for considerable dimensional disparity. A ton of cut flowers occupies many times more space than a ton of machine parts.

3. *Character of cargo* creates a need for specific space allocation. Refrigerated storage is required for perishable cargo, and other temperature controlled areas are needed for live cargo. Bonded storage is needed for customs, import/export control, as well as security accommodations for valuable cargo.

4. *Methods of handling and storing* cause variations in space requirements. Operations utilizing forklifts and pallets require more square footage for circulation and maneuvering.

The arrangement of space in the load build-up areas is also influenced by aircraft loading characteristics. Space should be planned for sequence loading to provide for distribution of weight in the aircraft and for easy removal of loads at destinations. Freight to be loaded on combination aircraft should be kept separate from freight to be loaded on all-cargo aircraft. Loads to be unitized on pallets, loads to be unitized in containers, and those to be loaded on aircraft manually should be controlled by providing separate but adequate space for each. The types of aircraft and the numbers of each type being served by the facility should be given careful study.

Consultation with the users as to the type of materials handling systems to be employed is essential and will be most helpful in this area of design. As materials handling systems for the air cargo industry are developed and improved, space requirements for the load build-up area and other operations may be reduced substantially. Figure 3 indicates diagrammatically suggested space requirements for receiving and processing areas.

Administrative Area, and Customer and Personnel Accommodations

Adequate administrative space is necessary for efficient management of cargo operations. A thorough analysis of the duties and responsibilities of the administrative personnel should

be made prior to preparing the design program of the building. The number of employees that may ultimately be employed in the management of operations should be studied.

Reception areas should be provided to handle customers. In addition to serving as a receiving point for visitors, small packages may be claimed or bills may be paid here. There should be sufficient space for a counter, accommodations for customers, and cases for display of brochures and other sales material.

Sales offices may be required by some airlines. Space in the sales office should provide for desks, files, and facilities for telecommunications. Files should be readily accessible to all the salesmen. The sales office may serve also as a customer service center or clearing-house for telephone inquiries. Close communication must be maintained between this office, receiving, aircraft space control, and accounting.

Management and general office space requirements are dependent upon variables such as the type of operation, the amount and type of freight processed, and the community being served. Accounting and records offices may be necessary facilities for operations of any sizable magnitude. The space required varies with the type of record keeping and accounting equipment that may be used such as automatic filing systems and data processing equipment.

Communications centers assist management in the efficient movement of freight. Each facility component must be kept informed of changes in schedule, cargo space available, and of special shipments requiring unusual attention. The communications center can serve as the central nerve system. It can provide the link between administration and operations. Space may be required for teletype machines and closed-circuit television facilities in addition to sufficient desk space for communications personnel.

Aircraft space control office requirements are dependent upon the amount of freight handling activity. This office may be placed in the receiving area or in the administration offices. Space must be provided for computing and communications equipment and for aircraft charts indicating cargo space available on the aircraft. These functions are closely related to those of receiving and processing and to those of the communications center. Provisions should be made to facilitate close liaison with these interrelated functions.

The number of personnel employed in cargo operations will vary not only with the type and volume of freight handled but also with the materials handling system used and the scheduling of aircraft loading operations. A careful study should be made of all factors including local codes and state labor laws to assure adequate provision for employee needs. Figure 3 indicates suggested space requirements. This overall area may be allocated to administration, customer accommodations, and personnel accommodations such as rest rooms, locker rooms, and lunchrooms. A first-aid room, pilot-ready room, or other specialized area may be included dependent on circumstances peculiar to proposed facilities.

Maintenance, Services, and Storage

In order to provide for an efficient operation, equipment must be kept in good working order at all times. Maintenance and storage of materials handling equipment, such as containers, should not be overlooked. The functions of maintenance and storage may be joined, or they may be completely separated. The manner in which these functions are handled depends largely on the type and amount of equipment used.

For large operations, maintenance and servicing shops may be necessary to provide repairs for such items as pallets and containers, forklift trucks, conveyors, and other materials handling equipment. Webbing used to secure freight against dislodgment in aircraft requires periodic repair. The maintenance and the servicing shops may be centrally located in the cargo complex, or they may be constructed as a part of the air carrier's individual freight handling facilities.

Garage or hangar space may be required for larger pieces of equipment, such as scissors lifts, mobile freight loaders, or other vehicles used in the freight loading operations. (In some cases, it may be economically more practical for the air carriers if this space and this type of equipment are furnished by the airport management on a rental basis.)

Space required for building utilities, such as plumbing, heating, ventilating, air conditioning, electricity, and gas depends primarily on the geographical location of the airport. Other factors, such as requirements of servicing equipment, type of fuel available in the area, and accessibility of public utilities to the airport cargo center, also must be considered. All utilities may be centrally located on the airport and furnished to users by airport management. Each building may house its own space for the provision of these utilities.

Special Handling

Some types of freight require special handling, that is, facilities and techniques not ordinarily used for normal items. Requirements depend on the policy of the air carrier in accepting shipments that require special techniques. Basically, four types of shipments which fall into the special handling category are live

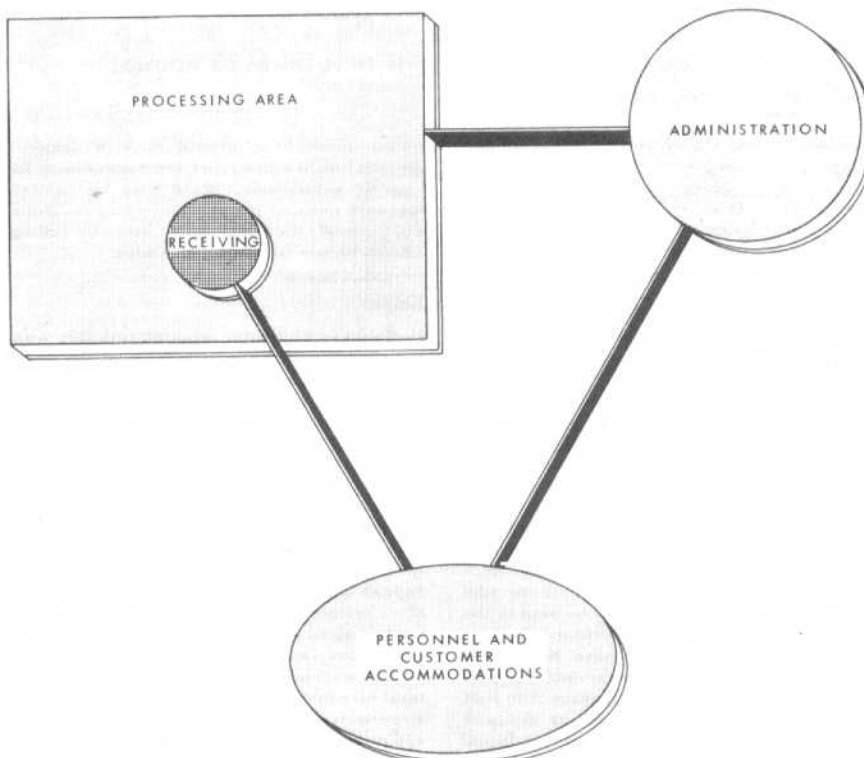

Fig. 2 Space relationships within buildings.

AIRPORT CARGO FACILITIES

animals, perishables (pharmaceuticals, meats, produce, and flowers), and bonded and valuable shipments.

If the volume of live animal shipments is expected to be large, special provisions for them should be given consideration. Heating, ventilation, cleaning facilities, fresh water supply, cages and stables, and storage facilities for handling, cleaning, and feeding equipment will require study. Consultation with the local chapter of the Society for Prevention of Cruelty to Animals (SPCA) is suggested.

Perishables are being shipped in increasing quantities. Bonded and other valuable freight processed varies not only with the economic character of the community but also with the seasons.

Facilities at International Airports

Air carriers providing service for overseas shipments at international airports will require space for inspection of deplaned freight. Consultation with Bureau of Customs, Agricultural Research Service, and Public Health Service officials in addition to the airlines is essential in developing a proper design program for this area.

Building Construction

Building design consistent with functional requirements and the need for economical construction and maintenance cannot be over-emphasized. Airport buildings are often constructed in areas beyond the jurisdiction of a city building code. Materials and methods of construction and design of an airport cargo building may or may not be governed by a building code of the local community or regulations established in state labor laws. When local codes are applicable, particularly in small communities, the standards designated in such codes are sometimes below those acceptable as good architectural or engineering practice for buildings on airports.

Selection of the structural system to be used for the building should be based on careful consideration of the insurance rates for various classes of building construction and occupancy. The initial cost of fire-resistant construction may be higher than other types of construction, but a lower insurance rate will often offset this higher initial cost. Fire is not the only hazard about which the designer must concern himself. Protection against pilferage, vandalism, or possible sabotage in time of emergency should be considered in choosing materials of construction. The location of the building and the types of commodities moved through the facility will also influence the type of construction.

Structural systems having the capability of economically spanning as much as 100 ft provide greater flexibility in building design and space arrangement. Clear-span structures are desirable because they allow for greater maneuverability of forklift trucks and other freight handling equipment. Large-space areas, free of columns and bearing walls, can be divided and adapted to satisfy the changing demands of functional operations. Roof construction and roof design loads vary with the area of the country.

Floor construction, according to the NBFU-recommended National Building Code, should be designed and constructed for the greatest loads that are anticipated by the user. Provision should be made for such items as floor scales, pit elevators, and recessed tracks for towveyor systems. Floors in the office areas, where extensive filing systems are maintained, should be designed to carry a minimum uni-

Fig. 3 Building area space requirements.

formly distributed load of 125 lb per square foot.

Selection of doors must be given careful consideration. Overhead and roll-up doors are suggested in areas where there is movement of freight. The tracks of the overhead-type door should be installed to provide as much headroom as possible within the building.

Bumpers and guards for protecting truck-dock edges are available in many designs. The nature of activity, the devices used for loading operations, and the amount of traffic are the determinants in making a selection. The use of bumpers and guards will help keep maintenance of dock areas to a minimum.

Interior finishes depend upon local factors, but they should be selected from the standpoint of minimum maintenance. The functional use of the area should be the determining factor in the selection of the finishes. In the processing and storage areas of the building, a smooth concrete finish for the floor should be adequate. A hardening additive may be used in the concrete to make a durable surface.

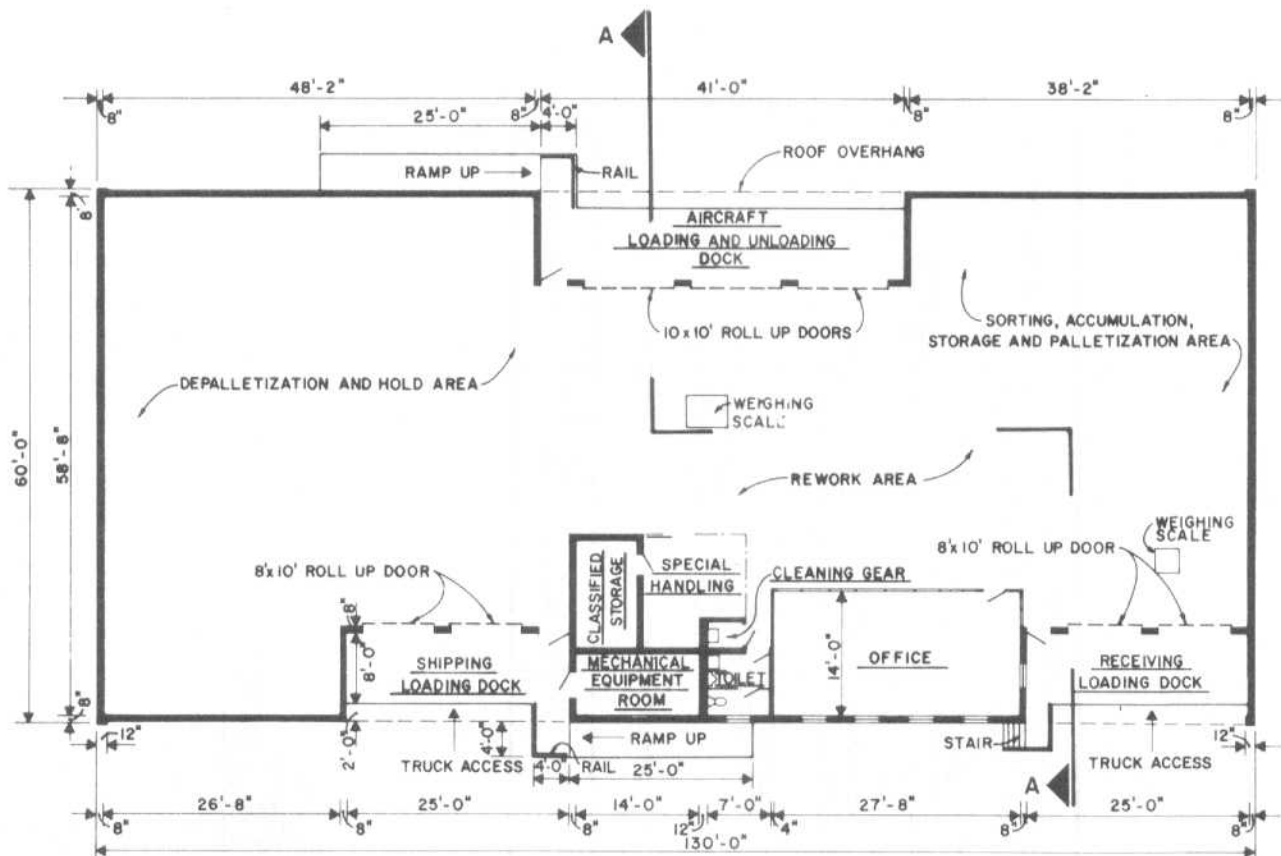

The toilet rooms should have floors and walls finished with a hard impervious material for ease of cleaning and maintenance. The wall finishes may be an integral part of the wall construction, such as glazed partition block or glazed brick where budgets permit. The

locker room floor should have a painted, smooth finished concrete floor if costs must be kept at a minimum. Walls may be painted masonry units or plaster. Since locker rooms are generally noisy places, an acoustic ceiling should be considered for this area.

Utilities

Heating and ventilating requirements vary with the climate and the requirements of the user. It may be possible to integrate systems with the humidity and temperature control required for handling special commodities. A system which will provide proper year-round conditioning of air particularly in administrative areas is important.

Electrical and lighting systems should be adequate for the designed functions. The requirements of the electrical service vary with the size and character of the facility. Much will depend upon the nature of the materials handling system used. Minimum required lighting levels may be governed by local codes or state labor laws; however, these may sometimes be below those acceptable as good architectural or engineering practice for buildings on airports. It is recommended that airport owners voluntarily adopt the standards from one of several recognized sources.

Fig. 2 SOURCE: U.S. Naval Facilities Engineering Command, Department of the Navy, Washington, D.C.

AIRPORT SERVICE EQUIPMENT BUILDINGS

BUILDING SITING

Importance of Site Planning

The service equipment building must be sited in a location that will contribute to the efficient operation and performance of equipment and personnel. The analysis and study to determine the location of the building is the most important single consideration presented in this discussion.

Location on the Airport

The study to determine the location for the service equipment building should consider the proper relationships of each of the essential airport building categories identified by activities related to the terminal and to administration, to commercial aircraft facilities, to other airport oriented operations, and to aviation oriented industry which may be located on the airport. Operational activities in addition to administrative functions are generally grouped according to the relationship to the services provided by governmental agencies, air traffic control, communications, and weather; to the service provided by airport management; to the aircraft sales, storage, maintenance, and flight training; and to air cargo, express, and air mail movements. The service equipment building and fire and crash rescue building are associated with a group of operational services provided by airport management for planning purposes. It is this relationship which may lead to the combining of facilities.

There are three principal considerations that should determine the location of this functional group of operation buildings including the service equipment building. It must be close to the heart of airport operations for control of maintenance and service activities. It must be accessible to airport service roads, particularly the airport perimeter road. This will permit the equipment to reach all operational areas of the airport without having to cross active runways. It must be centrally located with respect to airport pavement areas, particularly air carrier aircraft passenger loading aprons, to other public loading and servicing aprons, and to landing area facilities. Examples of specific locations which have been selected after reasonable consideration of factors discussed are shown in Fig. 1. Site locations are indicated by order of preference.

Planning Considerations

The location of the operational activity having been established and the preliminary design concept of the building selected, a number of other factors should be studied prior to adoption of a siting plan.

The arrangement of buildings and associated support facilities is important to satisfactory and efficient use, and it also affects future

extensibility of the equipment building to accommodate additional garage stalls. Important in this regard is consideration of spacing of buildings for access, vehicular circulation, and fire and safety clearances. The proper orientation of the building, with respect to these factors and the prevailing winds, is essential to the functional operation of the building. In any climate, an attempt should be made to orient the building so that the large door openings will be least exposed to prevailing winds. In snow country, an effort should be made to take advantage of wind movements to reduce drifting against the building and, where possible, to remove snow from vehicular entrance doors.

Since, under most circumstances, it will not be considered practicable to site the building adjacent to aircraft operational aprons, provision should be made for adequate circulation and unobstructed access. Economical design dictates the need for balance of requirements for paved areas with other considerations discussed heretofore. Good drainage consistent with driveway, parking, and pedestrian access requirements is also important.

THE BUILDING AND ITS SURROUNDINGS

Factors Affecting Space Requirements

The need for the facility having been clearly established, the next step is the design of the building and provision for required support items in the immediate surroundings. A review of the major factors affecting the need for a facility and a review of existing or contemplated airport maintenance procedures should provide an indication of what would constitute an adequate number of garage stalls for the equipment. No two airports can be expected to need exactly the same equipment or facilities. At some airports, a number of facilities may already be furnished in another building.

Some maintenance equipment, similar to construction equipment, will not require storage in a building of the type discussed herein. Also, some types of equipment, if adequately serviced and maintained, will not require shelter at all. At some airports, all servicing of vehicles may be done off the premises.

Office space is also an essential element to be considered in the functional design of the building. Storage for hand tools and parts, although not discussed in relationship to the various types of equipment, should not be forgotten in the analysis of space requirements. In addition, consideration should be given to the space required for personnel needs such as lockers, toilet and shower facilities, multipurpose rooms, and personnel equipment storage. At airports where few personnel are employed, separate locker rooms and storage facilities may not be needed.

Space Requirements

It has been found that there exists a closer relationship between the number of vehicles used for maintenance and the amount of airport pavement than between the amount of equipment and the number of operations or passengers using the airport. Table 1 is a tabular listing of runway lengths and the number of vehicle stalls found to be satisfactory at a representative group of airports. It is based on current usage figures. The application of these figures will provide general guidance where other data are not available.

Combination Facilities

A consideration affecting space requirements and space relationships is the advantages offered by combining facilities designed to meet a number of airport operational needs. At some airports, it may be desirable to consolidate the housing for fire and rescue apparatus and maintenance and service equipment into a single building. Airport management at an airport adjacent to large bodies of water may want to consider combined facilities at a site that would permit incorporating a facility to house a rescue boat. In every case, however, there are certain overriding factors, such as siting and accessibility for example, that must be considered in evaluating the advantages and disadvantages of combining different facilities.

There is an advantage in combining fire and rescue and service equipment facilities when personnel utilized as volunteer firefighters are maintenance personnel. This is particularly true when the airport management has under-

taken the training of these men to operate fire and rescue apparatus. Even where this is not contemplated, combined facilities may be economical and satisfactory provided facilities can be made available for total needs and other requirements can be met. The requirements peculiar to the fire and rescue operation must receive just consideration.

A certain degree of isolation of facilities in combination buildings is essential for security purposes as well as for functional reasons. A full partition separating the two functional areas and isolating fire department activities and equipment is a requirement. Apparatus room requirements are such that tandem parking of vehicles is not recommended for emergency equipment. Office and storage space to satisfy the needs of the fire department should be separate from similar facilities provided for service equipment operations.

At airports where a 24-hour crew coverage requires living facilities including a dormitory

for firefighters, the disadvantages associated with combining facilities override all other considerations. All of these factors must be evaluated. They are mentioned here preparatory to the detailed discussion of space relationships and other building elements that follows. Included in Fig. 2 is a typical layout showing space relationships which may be considered for a combined equipment building.

Space Relationships

Suggested space relationships for airports having varying equipment requirements are shown in Figs. 2 and 3.

Equipment and Servicing Stalls These should normally be between 12 and 14 ft wide and 40 ft long for typical equipment in order to allow a reasonable amount of space for circulation around each vehicle. Door openings of stalls should normally be 12 ft wide and 15 ft high

for typical equipment. While most service equipment will conform to highway clearances and vehicular standards, the trend is toward larger units for special equipment developed to meet the needs of airport operation. Where stalls may be arranged to provide tandem storage of vehicles, the allowance for each vehicle space may be reduced to 35 ft with the overall interior depth of the building being 70 ft. An example of this is indicated in Fig. 3. The ceiling height should be a minimum of 17 ft.

Office Space This should be sufficient to accommodate a desk, a few chairs, and a file cabinet, which should be provided for the maintenance superintendent. A room having an area of 100 sq ft would be adequate to fulfill this need at most airports.

Storage Space Storage space for tools and equipment should be provided adjacent to the stall area in which servicing of equipment

AIRPORT SERVICE EQUIPMENT BUILDINGS

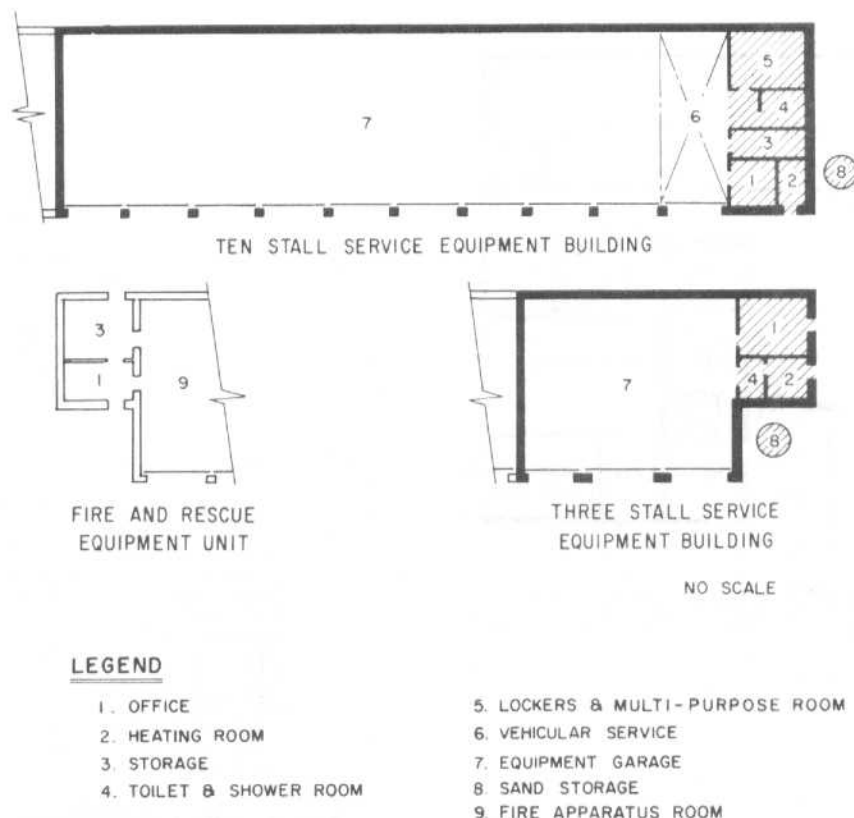

Fig. 2 Combination equipment buildings.

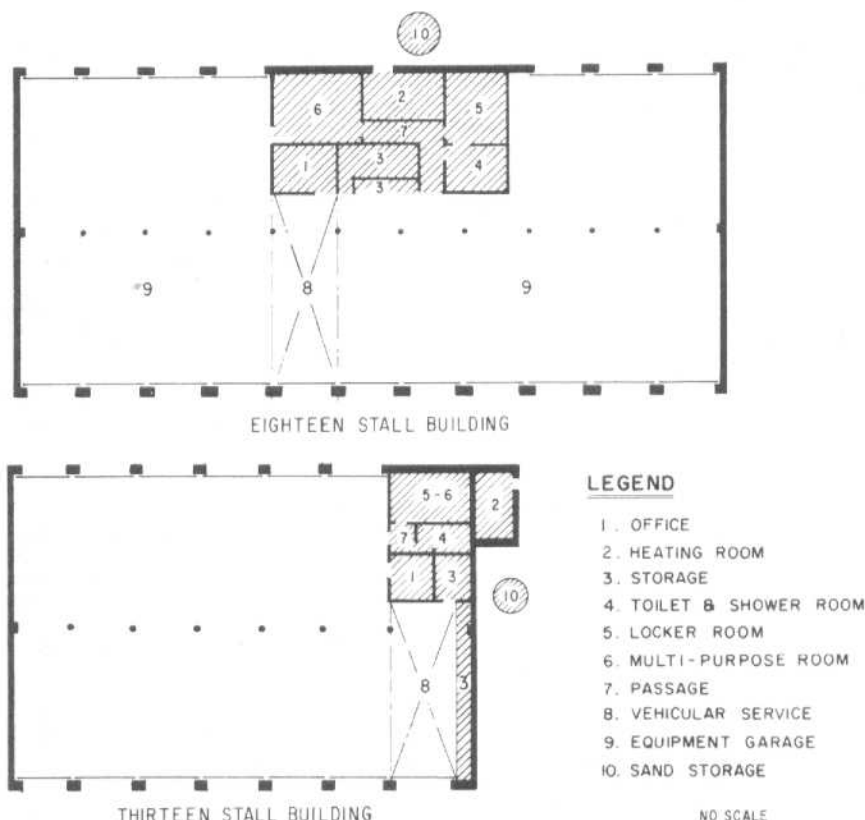

Fig. 3 Service equipment buildings.

is performed. A storage area of 60 to 80 sq ft would provide reasonably adequate space for this purpose. The space may be provided along one wall of the service area in a group of secured shelves or cabinets, in a separate storage room, or both. Smaller equipment and hand tools needed in addition to those used for servicing may also be stored in the space provided.

Personnel Accommodations

1. Locker room facilities may be provided at airports where five or more persons are employed for maintenance and service work. These facilities may be combined with a multipurpose room or other personnel accommodations. When the number of maintenance personnel approaches 14, completely separate locker room facilities should be considered. One locker, 15 in. wide, 22 in. deep, and 72 in. high, should be provided for each maintenance and service employee regularly employed at the airport. At small airports, where only a few maintenance personnel are employed, facilities for clothes storage and personnel needs may be more conveniently provided elsewhere than in the equipment building.

2. Toilet, lavatory, and shower facilities allowances should be based on the total number of maintenance and service operations personnel. Toilet and shower facilities should be located adjacent to the locker room, and provision should be made for reasonable access from all working areas of the building.

3. A multipurpose room may, under some circumstances, be considered desirable for employee lunchroom space when other eating facilities are not available on the airport. An allowance of approximately 10 sq ft per employee would be adequate.

Storage Adjacent to the Building

At airports where icy conditions are experienced and sanding is used as a method of maintaining safe operating surfaces under such conditions, availability of sand is often a problem. Where airports are not located sufficiently close to a quarry from which hot, dry sand can be procured readily, an adequate amount of sand should be stored in a dry condition on the airport.

At most airports where it is necessary to store sand, it has been found that between 250 and 300 tons should be readily available on the site. Since a problem arises when sand is stored in the open, various methods of providing for sand storage should be considered. Hot, dry sand is most desirable for spreading on icy surfaces. The dryness allows the sand to be spread effectively, and the heat sets the sand in the ice to provide a reasonably good abrasive surface.

Where practicable, it is recommended that sand storage be provided adjacent to the building. One of the most effective methods of storing sand is in an elevated silo or hopper. Where this can be located adjacent to the building, access for trucks loading beneath it and problems of providing heating can be simplified. Other methods of storage at grade may be satisfactory provided mechanical loading equipment is available.

AIRCRAFT FIRE AND RESCUE STATION

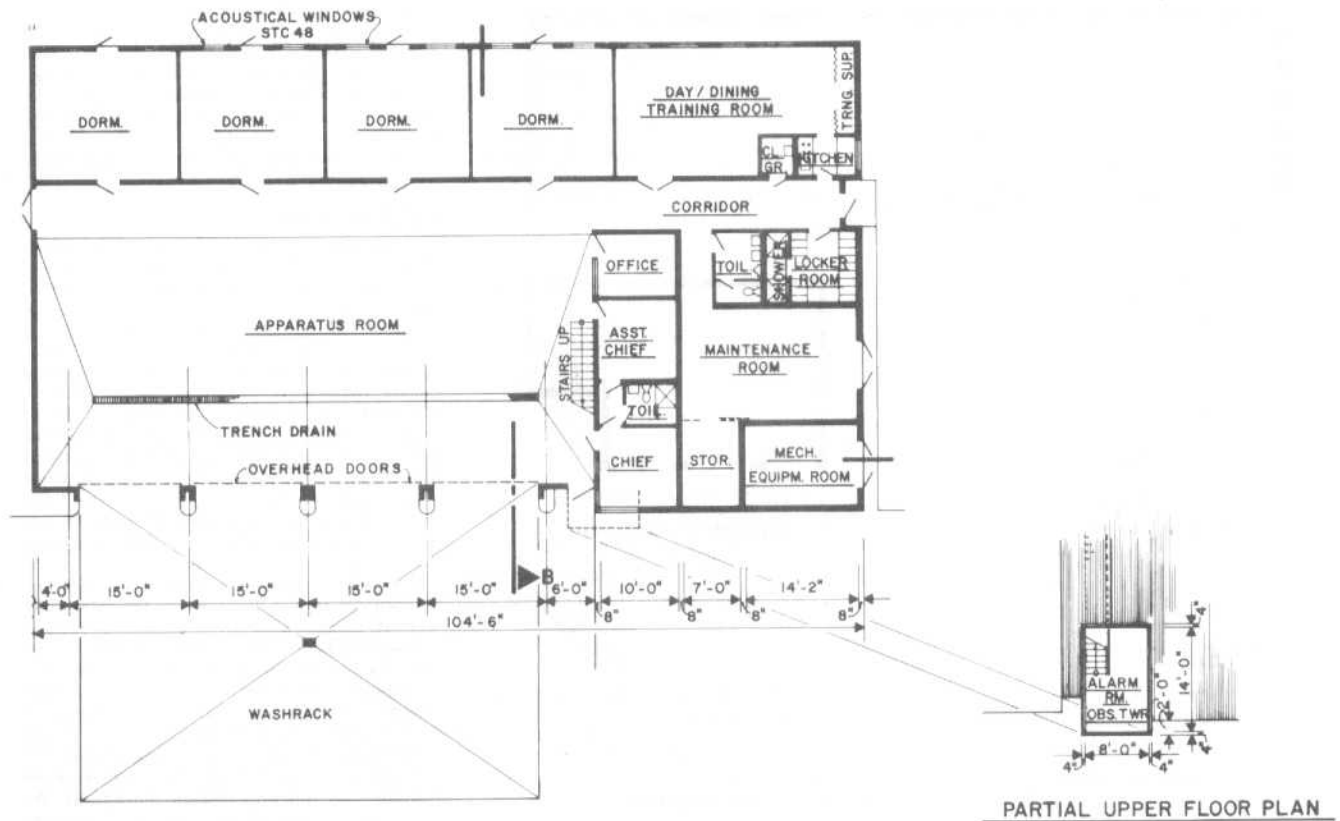

Fig. 1

GOVERNMENTAL ROLE

General Federal, state, and local governments have related but somewhat differing roles in the field of heliport development. Each has an obligation to assure that the public's interests are protected, yet each also has the responsibility to assist the public in developing a safe, efficient, and comprehensive transportation system. It is essential that heliport proponents contact FAA, state, and local authorities early in the planning stage in order to proceed with full knowledge of any regulatory requirements, assistance programs, or probable operational limitations. FAA offices and many state aviation departments are able to provide technical advice on heliport development and operations. Local governments frequently do not have heliport expertise, and proponents may find it necessary to explain the special nature of helicopter operations and how local approval will benefit the community.

Federal Role The federal government, through the FAA, has established standards for heliport development and rules for helicopter operations. Through its Federal Aviation Regulations (FAR), the FAA prescribes various requirements that must be observed by the heliport owner and helicopter operator which affect heliport development. The regulations are comprehensive and concern such matters as minimum safe altitudes, ceiling and visibility limitations, aircraft and pilot licensing, and related standards appropriate to assure the safety of persons and property both in the air and on the ground. The purpose for such broad regulations is to achieve safety through the uniform and standardized control of aviation operations.

Environmental Considerations An environmental assessment is required for all federally assisted heliport development in accordance with the requirements of the National Environmental Policy Act of 1969 and the Airport and Airway Development Act of 1970, as amended. Consult with an FAA airports office for guidance on this important aspect of heliport development.

State Role Many state aeronautics commissions or similar authorities require prior approval, and in some instances a license, for the establishment and operation of a heliport. Requirements will vary from state to state. Some state requirements apply only to public-use heliports, whereas others apply to any heliport. A few states administer financial grant programs similar to the federal program for airport development. Heliport proponents should contact their respective state aviation departments for particulars on licensing or assistance programs.

Local Role Most communities have zoning laws, building codes, fire regulations, or similar ordinances. Some have, or are in the process of devel-

oping, ordinances covering environmental matters such as noise and air pollution. A few may have specific rules or regulations governing the establishment and operation of airports (heliports). Therefore, a careful study should be made to determine whether local laws, rules, and regulations permit the establishment and operation of a heliport. It is also important to determine if these same laws permit helicopter landings to be made at places other than a heliport on a one-time, temporary, or infrequent basis without formally declaring the site a heliport.

HELIPORT CLASSIFICATION

General The terms used to classify United States heliports are descriptive of the class of user allowed to conduct flight operations from the facility.

Military Heliport The term "military heliport" is applied to heliport facilities operated by one of the uniformed services. Military heliports are developed in accordance with the design criteria of the applicable service and generally prohibit nonmilitary usage.

Federal Heliport The term "Federal heliport" is applied to heliport facilities operated by a nonmilitary agency or department of the United States Government. Most Federal heliports are operated by the Departments of Agriculture (DOA) and Interior (DOI). DOA and DOI heliports are located in national forests or national parks and are used to carry out departmental responsibilities for land management and fire suppression activities. Generally, DOA and DOI heliports are restricted to departmental usage.

Public-Use Heliport The term "public-use heliport" is applied to any heliport that is open to the general public and does not require prior permission of the owner to land. However, the extent of facilities provided may limit operations to helicopters of a specific size or weight. A public-use heliport may be owned by a public agency, an individual, or a corporation so long as it is open for public use.

Private-Use Heliport The term "private-use heliport" is applied to any heliport that restricts usage to the owner or to persons authorized by the owner. Most private-use heliports are owned by individuals, companies, or corporations. However, a heliport designated as "private-use" may be owned by a public body. In this case, the private-use classification is applicable because the facility is restricted to a specific type of user, such as the police department, or because the owner requires prior permission to land. Hospital heliports are considered private-use facilities since operations are normally restricted to medical-related activities.

Personal-Use Heliport The term "personal-use heliport" is applied to any heliport that is used exclusively by the owner. Personal-use heliports are owned by individuals, companies, or corporations.

SELECTING A HELIPORT SITE

General Increased public awareness of the helicopter's capabilities has enhanced its prominence as an important vehicle in the national transportation system. Continuing advances in helicopter productivity and operating economics make it reasonable to anticipate increasing public and private usage for intra- and interarea transportation. However, optimum public benefits cannot be realized without an adequate system of public-use heliports. Stage development is encouraged when it is unnecessary or uneconomical to construct the ultimate heliport. Early coordination with FAA airports offices on adequacy of the proposed stage construction and ultimate design of the heliport and with FAA Flight Standards offices on operational procedures and limitations is encouraged.

Location To be most effective, heliports should be located as close as conditions or circumstances permit to the actual origins and destinations of the potential users. In some communities, this might require a heliport to be located in an area that could be described as congested or highly developed. In many instances, a practical, safe, and economical ground-level heliport can be established on a portion of an automobile parking lot that is fenced off to control access. If a ground-level site is unavailable, it is possible to locate the heliport on the roof of a building or on an unused pier or wharf. Elevated or overwater heliport sites will have in many instances an advantage over ground-level heliport sites since public access can be more easily controlled and unobstructed approach-departure paths may be easier to obtain. Other considerations in heliport siting are the locations of populated areas, noise-sensitive developments, and the existence of objects in the proposed approach-departure paths.

Layout The physical layout of the heliport is primarily dependent upon the operating characteristics of the helicopters to be accommodated and the type of support facilities desired. A relatively modest site will suffice if a minimum takeoff and landing facility capable of accommodating one small helicopter is all that is desired. Even though helicopters can maneuver in relatively high crosswinds, the approach-departure paths should be oriented to permit operations into the prevailing winds.

Heliports at Airports The location and extent of separate takeoff and landing facilities to serve helicopter operations will vary from airport to airport. Most airports would probably find it advantageous to establish facilities and procedures to separate helicopter and airplane traffic. These helicopter takeoff and landing facilities may be developed on a portion of the apron or on an infield site adjacent to an apron or taxiway. When helicopters are scheduled to connect with airline flights, the helicopters should be allowed to board and discharge passengers in close proximity to the airline check-in areas. To the extent possible, locate facilities to avoid mixing helicop-

HELIPORTS

ter operations with airplane operations. Clearance between the helicopter takeoff and landing facility and the airport's active runway(s) should be in accordance with the heliport-to-runway separations of Table 1.

TABLE 1 Heliport-to-Runway Separations at Airports (by Airplane Category)

Single-engine propeller airplanes	Twin-engine propeller airplanes	All other airplanes
300 ft (90 m)	500 ft (150 m)	700 ft (210 m)

NOTES:

1. The above table shows the minimum recommended separations between a separate heliport facility and an airport runway for simultaneous operations in VFR conditions.

2. FAA wake turbulence avoidance procedures must be followed with heliport-to-runway separations under 2,500 ft (750 m).

3. At controlled airports, two-way radio communication is required to be maintained with the aircraft involved so that pertinent traffic information may be issued.

4. When airplanes of different categories are involved, use the separation required for the larger airplane category.

Transportation Studies The proponent of a public-use heliport should review all transportation studies for the area. These studies frequently identify area origin-destination patterns and provide descriptions of existing and proposed public transportation systems. The studies may also describe existing and projected land development patterns for commercial, industrial, public, and residential usage and zoning actions taken to permit or to encourage such usage. Some studies may have identified tentative public-use heliport locations. Communities planning urban renewal projects may find the inclusion of a public-use heliport to be the catalyst needed to attract desirable commercial or industrial development.

Operational Safety A major consideration in heliport siting is the availability of suitable approach-departure paths. It is preferable for helicopters to make takeoffs and landings into the prevailing winds but in some situations this may not be possible. In congested areas it may not be possible to develop a straight-in approach or departure procedure and a curved approach-departure path may be necessary to avoid obstacles. In other situations special letdown and climb-out procedures may be desired to confine helicopter sounds to a small area near the heliport. Helicopter approach or departure procedures are developed for each heliport on the basis of site conditions, helicopter capabilities, and the type and number of activities to be conducted therefrom. When necessary, the FAA may condition an airspace decision by requiring special flight routes, altitudes, or approach and departure procedures in the interest of user safety and airspace compatibility.

Local Regulation Because helicopters can operate safely at sites of limited size, it is quite likely that heliports may be suggested for areas that have not been exposed to significant aviation activity. Consequently, the heliport proponent may have to take a substantial and active role

in educating the public about heliports and helicopters.

Land-Use Zoning Zoning ordinances should be written to permit heliports as an accepted land use in areas identified for industrial, commercial, manufacturing, or agricultural uses and in any area that is unzoned. Some heliports, especially those without support facilities, could be a permitted use in certain residentially zoned areas.

Height Restriction Zoning The desire for clear approach-departure paths is an important consideration in selecting a heliport site. When state-enabling legislation permits, communities are encouraged to protect heliport approach and departure paths by enacting height restriction zoning.

Environmental and Other Considerations The establishment of a heliport may have an impact on the community in terms of noise, exhaust emissions, public safety, ground traffic, aesthetics, and

attitude. When federal aid is used, an environmental impact assessment report is required to assist the federal agency in making the environmental decision. A similar report may be required by state or local authorities.

Noise The impact of helicopter engine and rotor sounds upon populated areas is an important consideration in selecting a heliport site. Since helicopter sounds are greatest directly beneath the takeoff and landing paths, these paths should be located over sparsely populated areas, over areas that have an already high level of background sounds, or over areas that would be expected to have a high tolerance level to helicopter sounds. Improvements resulting from ongoing research activities to reduce the sounds generated by engines and rotors will be incorporated in future helicopters as quickly as economic and technological conditions permit.

Exhaust Emissions Relatively few civil-use heliports have sufficient flight operations for exhaust

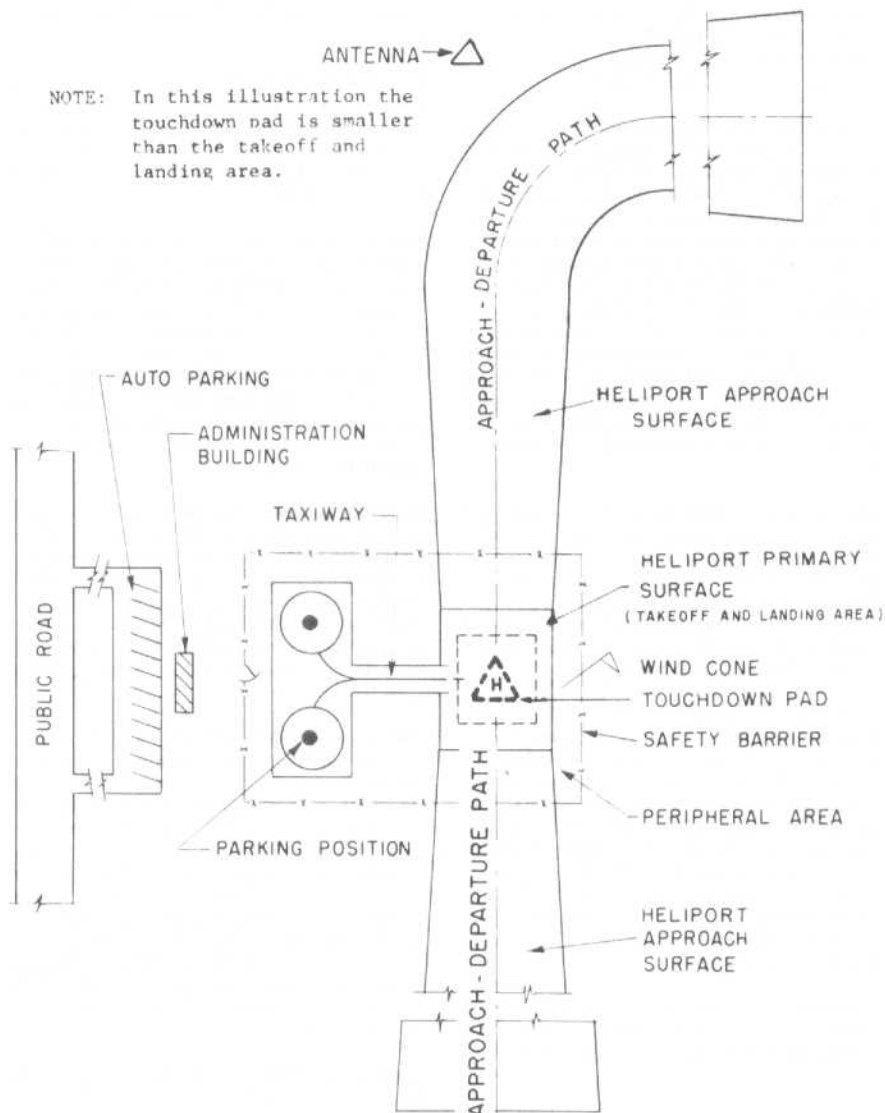

Fig. 1 Relationship of heliport surfaces.

HELIPORTS

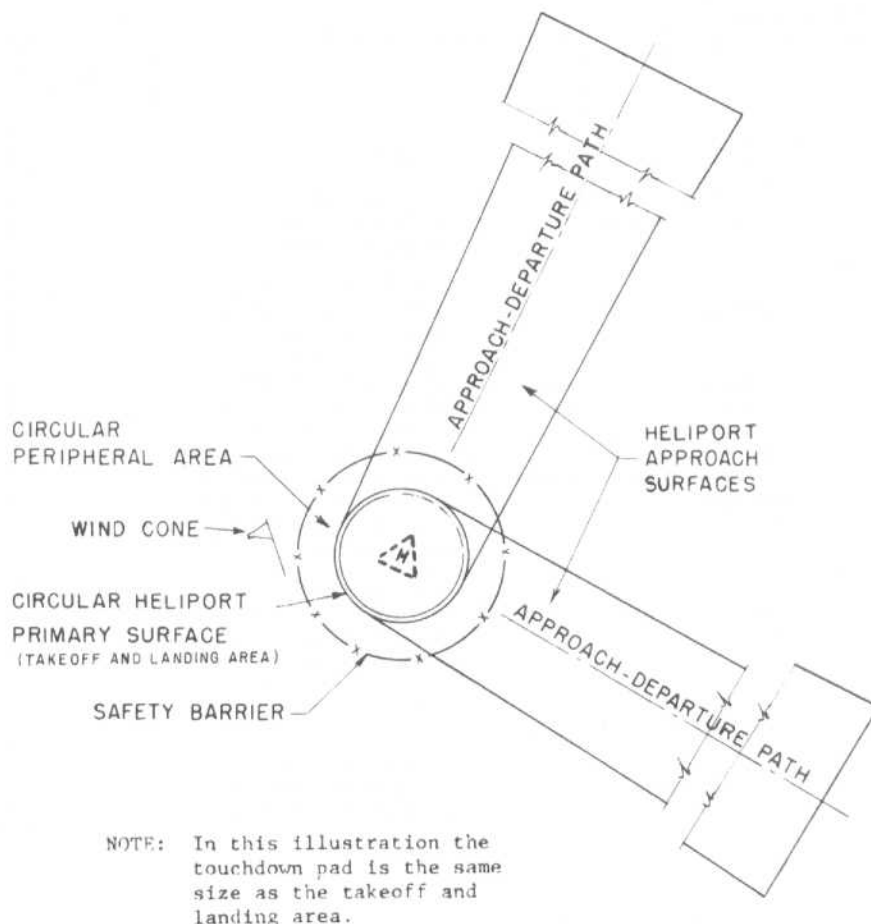

Fig. 2 Relationship of heliport surfaces for a minimal "circular" facility.

emissions to be considered a significant problem. Research on aircraft fuels and engines to reduce pollutant levels will also be applicable to helicopters.

Public Safety Heliport sites and approach-departure paths should be selected to avoid areas of public concentration. The approach-departure paths should also be free, and capable of being maintained free, of objects that interfere with helicopter movement to and from the heliport.

Ground Traffic Potential problems with passenger ground ingress or egress to a heliport may be minimized if there is direct access to an adjacent major roadway. Access to one or more modes of public mass transit is desirable. A freeway environment has some inherent advantages over other sites. First, helicopter sounds may be undetectable over the existing background noises. Second, approach-departure paths can frequently follow the freeway right-of-way which is generally unencumbered with objects that would be hazardous to flight safety.

Aesthetics Community acceptance of ground-level heliports can be enhanced if the facility has an attractive appearance. Attractive buildings and carefully planned walls, fences, hedges, etc., are to be encouraged.

GROUND-LEVEL HELIPORT DESIGN

General The need for adequate heliport facilities is not limited to the centers of large cities. Public acceptance of the helicopter has encouraged heliport developments in suburban areas, in communities of quite moderate size, and in locations that are difficult to reach by other modes of transportation.

Heliport Layout The size, shape, and appurtenances of a heliport are determined by a number of interrelated factors, principal among them are the size and nature of the proposed site; the size, number, and performance capabilities of the helicopters expected to use the facility; the type and extent of services to be provided; and the location and height of buildings or other objects in the heliport area. The recommended minimal heliport facility consists of a takeoff and landing area, a peripheral area, and an approach-departure path. A large heliport may have several takeoff and landing areas and approach-departure paths, separate parking positions, and extensive passenger and helicopter servicing facilities. A takeoff and landing area may take any shape necessary to fit the site, but most heliports are configured as squares, rectangles, or circles. Figures 1 through 3 illustrate the relationship of heliport surfaces. With few exceptions, heliport di-

mensions are expressed in units of helicopter length or rotor diameter. Heliport dimensions are summarized in Table 2.

Takeoff and Landing Area For ground-level heliports, the length and width or diameter of the takeoff and landing area is recommended to be at least 1.5 times the overall length of the largest helicopter expected to use the facility. Under some design conditions, the definable and designated takeoff and landing area may be physically incapable of supporting a helicopter and/or may be impossible or impractical to mark or light.

Peripheral Area The peripheral area is intended as an obstacle-free safety area surrounding the takeoff and landing area. It is recommended that the peripheral area width be one-fourth of the overall length of the largest helicopter expected to use the facility, but not less than 10 ft (3 m).

Approach-Departure Paths Approach-departure paths are selected to provide the best lines of flight to and from the takeoff and landing area considering prevailing winds; the location and heights of buildings or other objects in the area; and the environmental considerations. It is desirable for a heliport to have two approach-departure paths separated by an arc of at least 90 degrees. However, under some conditions, operations at heliports with one approach-departure path may be conducted safely. Curved approach-departure paths are permitted and may be necessary in some cases to provide a suitable obstruction-free path. The radius of the curve is dependent upon the performance capabilities of the helicopters using the facility and the location and height of existing objects. Areas suitable for an emergency landing are desired along the approach-departure path unless the heliport is used exclusively by multiengine helicopters with proven capabilities to continue flight with one engine inoperative.

Heliport Imaginary Surfaces The imaginary surfaces of subparagraphs *b* and *c* below represent idealized heliport design standards. They are not operationally limiting in cases where an onsite evaluation concludes that surfaces steeper than those recommended would not have an adverse effect upon the safety of a particular operation. However, any object which would exceed the published standards for defining heliport imaginary surfaces is considered an obstruction to air navigation. These surfaces are described below and are depicted on Figs. 1 through 3.

a. Heliport Primary Surface The area of the primary surface coincides in size and shape with the designated takeoff and landing area of a heliport. This surface is a horizontal plane at the elevation of the established heliport elevation.

b. Heliport Approach Surface The approach surface begins at each end of the heliport primary surface with the same width as the primary surface and extends outward and upward for a horizontal distance of 4,000 ft (1 220 m) where its width is 500 ft (152 m). The slope of the approach surface is 8 to 1 for civil heliports.

c. Heliport Transitional Surfaces These surfaces extend outward and upward from the lateral boundaries of the heliport primary surface and from the approach surfaces at a slope of 2 to 1 for a distance of 250 ft (76 m) measured horizontally from the centerline of the primary and approach surfaces.

HELIPORTS

TABLE 2 Summary of Recommended Design Criteria

DESIGN FEATURE	HELIPORT CLASSIFICATION		COMMENT
	PUBLIC-USE	PRIVATE-USE PERSONAL-USE	
	DIMENSION		
TAKEOFF & LANDING AREA Length, width, diameter	1.5 × helicopter overall length		To preclude premature obsolescence, consider the possibility of larger helicopters in the future.
TOUCHDOWN PAD Length, width, diameter	1.0 × rotor diameter		Elevated touchdown pads less than 1.5 rotor diameters in size may subject using helicopters to operational penalties due to loss of rotor downwash ground effect. Minimally sized touchdown pads are not encouraged, but may be used in cases of economic or aesthetic necessity. Touchdown pads less than one rotor diameter in size should have additional nonload-bearing area for downwash ground effect.
Minimum ground-level Length, diameter width	2.0 × wheelbase 2.0 × tread	1.5 × wheelbase 1.5 × tread	
Minimum elevated Length, diameter Width	1.0 rotor diam. 1.0 rotor diam.	1.5 × wheelbase 1.5 tread	
PERIPHERAL AREA Recommended width Minimum width	1/4 helicopter overall length 10 ft (3 m)		An obstacle-free area surrounding the takeoff and landing area. Keep the area clear of parked helicopters, buildings fences, etc.
TAXIWAY Paved width	Variable, 20-ft (6 m) minimum		Paved taxiways are not required if helicopters hover taxi.
PARKING POSITION Length, width, diameter	1.0 × helicopter overall length		Parking position should be beyond the edge of the peripheral area. Parked helicopters should not violate the 2:1 transitional surface.
PAVEMENT GRADES Touchdown pad, taxiways, parking positions	2.0% maximum		
OTHER GRADES Turf shoulders, infield area, etc.	Variable, 1.5 to 3%		A 10-ft (3 m) wide rapid runoff shoulder of 5% slope is permitted adjacent to all paved surfaces.
CLEARANCES, ROTOR TIP TO OBJECT Taxiways, parking positions	10-ft (3 m) minimum		Consider possibility of larger helicopters in the future.
HELICOPTER PRIMARY SURFACE Length, width, diameter Elevation	1.5 × helicopter overall length Elevation highest point takeoff & landing area.		Imaginary plane overlying the takeoff and landing area. Area to be free of all obstacles.
HELICOPTER APPROACH SURFACE Number of surfaces Angular separation Length Inner width Outer width Slope	Two 90° min., 180° preferred 4,000 ft (1 220 m) 1.5 × helicopter overall length 500 ft (152 m) 8:1		Protection for helicopter approaches and departures. The surface should not be penetrated by any objects that are determined to be hazards to air navigation.
HELICOPTER TRANSITIONAL SURFACE Length Width Slope	Full length of approaches and primary surface. 250 ft (76 m) measured from approach & primary surface centerline 2:1		Surface should not be penetrated by objects.

ACCEPTABLE RANGE OF ANGLES BETWEEN APPROACH-DEPARTURE PATHS
WHEN MORE THAN ONE APPROACH-DEPARTURE PATH IS PROVIDED

Fig. 3 Perspective of heliport surfaces.

NOTES:

1. The triangle, letter "H," and boundary markings are white and may be edged with a 6-inch (15 cm) black border to improve contrast. The boundary marking may be either a solid or segmented line.
2. The triangle is centered in the middle of the touchdown pad with the solid apex pointing magnetic north. The letter "H" is centered within the triangle.
3. Dimensions shown are appropriate for touchdown pads 60 feet (18 m) or larger. Dimensions should be reduced proportionally for smaller touchdown pads.

Fig. 4 Standard heliport marking symbol.

HELIPORTS

NOTES:

1. Markers used to define the takeoff and landing area of a turf landing area should provide visible contrast against the natural background of the site.
2. Flush-type markers may be located at the edge of the touchdown pad.
3. Above-ground markers should not project more than 18 inches (45 cm) above the surface of the ground. Manmade markers should be solidly anchored to the ground to prevent their being blown about by rotor downwash. Raised markers should be located at the outer edge of the peripheral area.
4. This drawing illustrates numerous types of markings that could be used to identify limits of a turf landing area. It is not intended that a heliport owner use more than one type of marker.

Fig. 5 Examples of markings for a turf landing area.

Paved Takeoff and Landing Areas Paved takeoff and landing areas at ground-level heliports are usually developed to support heavier helicopters or to accommodate greater traffic volumes. While it is desirable to pave the entire takeoff and landing area, there is no operational requirement to do so. When it is intended for the helicopter to touch down on a designated takeoff and landing area, a paved touch-down pad located in the center of the area, the size of either *a* or *b* below, will suffice.

a. Touchdown Pad The recommended dimension of a touchdown pad is equal to the rotor diameter of the largest helicopter expected to operate from the facility.

b. Minimum Touchdown Pad At a heliport that has an extremely low level of activity or is subject to economic or aesthetic pressure, smaller paved areas may be used. Pad dimensions are based on rectangular configurations. A circular pad having a diameter equal to the longer side of the rectangular configuration set forth in (1) or (2) below is acceptable. Skid or float length should be substituted for wheelbase as appropriate.

(1) *Public-Use Heliports.* The minimal-sized touchdown pad for a public-use heliport should have a length and width at least 2.0 times the wheelbase and tread, respectively, or a diameter of 2.0 times the wheelbase of the largest helicopter expected to use the facility.

(2) *Private-Use or Personal-Use Heliports.* The minimal-sized touchdown pad for a private-use or personal-use heliport should have a length and width at least 1.5 times the wheelbase and tread, respectively, or a diameter of 1.5 times the wheelbase of the largest helicopter expected to use the facility.

Parking Areas Requirements for physically separated helicopter parking areas will be based on operational needs. Each parking position, whether used for passenger boardings, helicopter servicing, or extended parking, is recommended to have a length and width or diameter equal to the overall length of the largest helicopter expected to use the facility. A minimum clearance of 10 ft (3 m) is recommended between adjacent parking positions or between a parking position and a fence or other object.

Taxiways Taxiways connect one operational area on a heliport with another. Most often, taxiways connect the takeoff and landing area with helicopter parking positions. Helicopters with wheel undercarriages normally are taxied in ground contact. Helicopters with skid or float gear must hover taxi. The minimum recommended paved taxiway width is 20 ft (6 m). Paved taxiways are not required for hover taxiing. A lateral clearance of at least 10 ft (3 m) is recommended between the blade tip of the taxiing helicopter and any building or object.

Heliport Buildings Heliports may require an administration or passenger service building, service and storage hangars, or maintenance buildings. The location and space requirements of heliport buildings will depend upon the extent of current and projected operations.

HELIPORT VISUAL AIDS

General Recommendations for marking and lighting of ground-level heliports are based on tests conducted for the FAA with the cooperation and involvement of civil and military helicopter pilots. For day VFR operations, it is recommended

that the takeoff and landing area be marked and that the heliport be equipped with a suitable wind direction indicator. For night VFR operations, it is recommended that the takeoff and landing area and the wind direction indicator also be lighted and a heliport identification beacon be installed.

Marking FAA standards for marking heliports serve two purposes. One type of marking serves to identify the heliport's designated takeoff and landing area and provides visual approach cues to the pilot. The second type of marking provides guidance for ground movement and helicopter parking. Markings may be painted on paved surfaces using reflective or nonreflective paint of the recommended color. A 6-in (15-cm), or wider, black (red for hospital heliports) border may be used to enhance painted markings. The marking of turfed heliports may be accomplished in a variety of ways.

Identification Markings Heliport markings identifying the takeoff and landing area are white. They are centered on the designated take-

off and landing area. Dimensions for these markings are shown on the referenced figures. The standard heliport marker (Fig. 4) is recommended to identify the designated takeoff and landing area of a heliport. While this symbol is widely used throughout the helicopter industry, a number of private-use and personal-use heliports are either not marked at all or utilize a company logo or some other marking recognized by the helicopter pilots authorized to use the facility.

Touchdown Pad Boundary Markings Boundary markings are white and are used to delineate the limits (edges) of the portion of the takeoff and landing area capable of supporting the helicopter. Paved surfaces may be marked by a solid or segmented white paint stripe at least 18 in (45 cm) in width. Black edging may be used to improve contrast. Turf heliport takeoff and landing areas may be delineated in a variety of ways. Figure 5 illustrates possible methods. Individual markers are spaced from 25 ft (7.5 m) to 100 ft (30 m) apart as site conditions dictate. A soil sterilant or an impervious membrane should be used to deter vegetation when a 3- to 4-inch (7

to 10 cm) thickness of crushed stone is used for markings.

Guidance or Position Markings All painted heliport guidance and positioning markings are yellow. These markings are primarily intended to assist pilots in ground movement and to aid in judging clearances between turning rotors and other aircraft or fixed objects. The markings are illustrated in Fig. 6.

Other Markings Passenger walkways and fire extinguisher locations should be appropriately marked.

- (1) **Walkways.** Passenger ingress and egress routes must be marked to indicate the safe walkway. The width, location, color, and marking are at the owner's discretion. Figure 6 illustrates one method of marking. Walkways should be textured to insure positive footing.
- (2) **Fire Extinguisher Locations.** Fire extinguisher locations should be marked for ready identification. A bright red circle 3 ft (1 m) in diameter is suggested. Figure 6 illustrates one method of marking a fire extinguisher position on an access-controlling fence.

ELEVATED HELIPORT DESIGN

General An elevated heliport, whether it be located on the roof of some building or parking structure or on a waterfront pier, presents unique design problems. Developing structural design and construction specifications for elevated heliports requires the services of qualified architects and engineers. This section is limited to covering, in general terms, the basic design features that are peculiar to an elevated heliport.

Siting When a suitable ground-level site is unattainable, the alternative may be the development of an elevated heliport. Elevated heliports are found in many cities. Most would be classified as private-use or personal-use facilities. An elevated facility has two advantages for the proponent of a private-use or personal-use heliport. First, the facility provides more privacy and security than a ground-level site. Second, with the heliport at or above the level of most buildings in the vicinity, there are fewer problems in providing and maintaining suitable approach-departure paths.

Codes and Regulations Local, state, and national safety codes pertaining to building construction, occupancy, ingress-egress, fire safety, etc., should be carefully reviewed to determine their impact on establishing and operating an elevated heliport. Early coordination of a proposed elevated heliport facility with FAA, state, and local authorities is recommended to insure that no pertinent code or regulation is overlooked.

Takeoff and Landing Area The dimensions of the takeoff and landing area of an elevated heliport are keyed to the size of the helicopter expected to operate therefrom. To the extent that circumstances permit, the recommended dimensions of the takeoff and landing area are identical to those of a ground-level facility. The takeoff and landing area, together with the associated peripheral area, may require the entire roof area or only a part of it. Elevated takeoff and landing areas

NOTES:

1. All markings for helicopter parking or ground guidance are in yellow.
2. Stopping circle "A" is at least 3 feet (1 m) in diameter. Diameter of the parking circle "B" is equal to the overall length of the design helicopter. Clearance to objects "C" is at least 10 feet (3 m).
3. Passenger walkway widths, locations, and markings are at the owner's discretion, the intent being to clearly delineate safe passageways.

Fig. 6 Heliport guidance, position, and other markings.

HELIPORTS

having a long axis should have that axis oriented in the direction of the prevailing winds.

Peripheral Areas In some instances, it is neither possible nor practical to provide the surface area required to permit the development of a takeoff and landing area and associated peripheral area. In some of these cases, it is reasonable to presume that the natural open space surrounding an elevated heliport will suffice as an obstruction-free area and the peripheral area requirement may be eliminated. To take full advantage of ground effect, the dimensions of the minimal takeoff and landing area should be 1.5 times the rotor diameter of the largest helicopter expected to operate therefrom. A surface smaller than this may subject using helicopters to operational restrictions.

Load-Bearing Surfaces The entire rooftop surface designated as the takeoff and landing area, plus any helicopter parking positions, should be designed to support the static and dynamic loads imposed by the largest helicopter expected to use the facility. Where a touchdown pad or parking position is to be provided, and it is impractical to structurally stress the entire takeoff and landing area, then an area of at least the size of (1) and (2) below should be provided.

- (1) **Public-Use Heliports.** A load-bearing area at least one rotor diameter in length and width, or a diameter of the largest helicopter expected to use the facility, is the minimum recommended.
- (2) **Private-Use and Personal-Use Heliports.** A load-bearing area having a length and

width at least 1.5 times the wheelbase and tread, respectively, or a diameter 1.5 times the wheelbase of the largest helicopter expected to use the facility, is the minimum recommended. Skid or float length should be substituted for wheelbase as appropriate.

Approach Clearances Elevated heliports have the same requirements for approach clearances as a ground-level heliport. At an elevated facility, it is usually easier to secure unobstructed approach and transitional surfaces. This benefit alone may be quite significant to privately owned heliports since approach and transitional surfaces usually cannot be protected under the zoning powers of the community. In many instances, it will be difficult to prevent obstructions within the entire rooftop takeoff and landing area. Therefore, special consideration may have to be given to the presence of penthouses, air-conditioning towers, exhaust stacks, antennas, etc. The FAA should be contacted early in the planning stages to undertake a study to determine the effect of such objects upon aeronautical operations. Elevated heliports may also be subjected to turbulence. Flight tests are recommended to ascertain the effect of different wind conditions on the safety of flight operations.

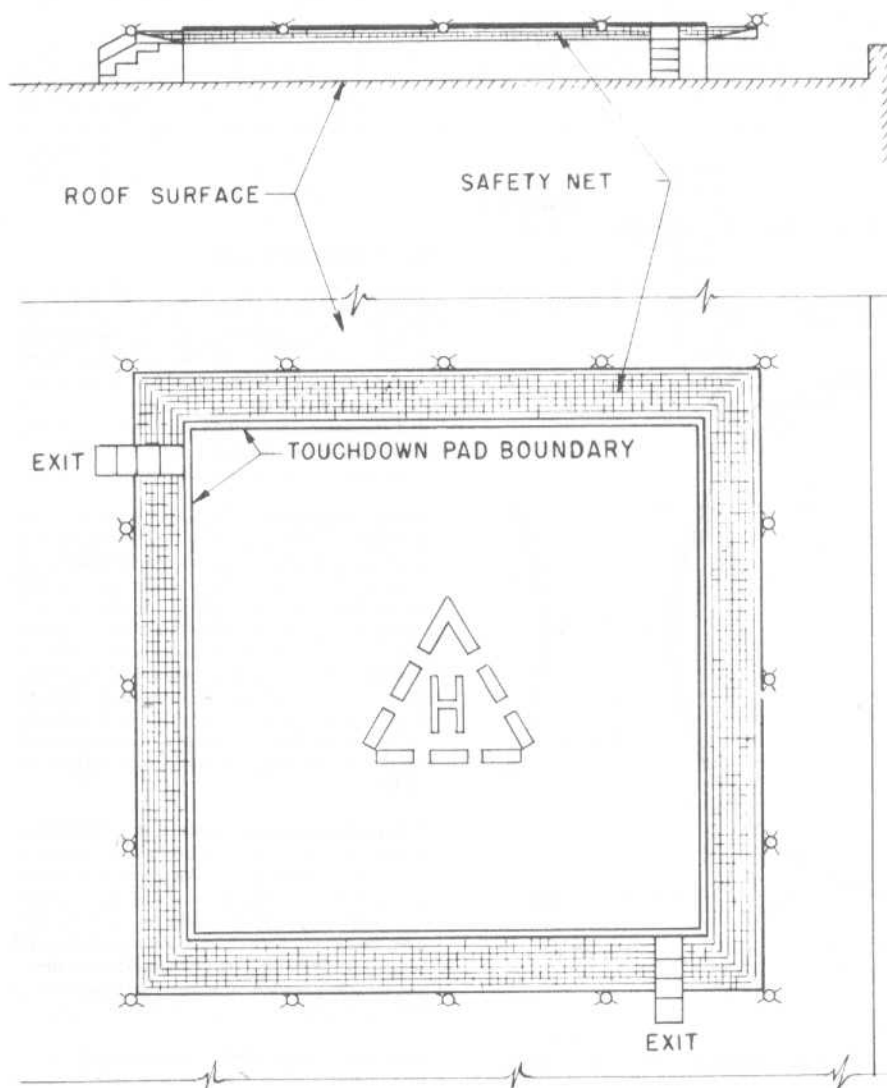

Construction—General Elevated heliport takeoff and landing areas present some special problems to the heliport designer who must consider the following factors.

Construction Materials All materials used in the construction of the heliport should be noncombustible or fire-retardant. Most frequently used materials are portland cement concrete, asphaltic concrete, steel plates, or treated wood. Synthetic and resilient plastic coatings of different compositions have been proved to possess excellent characteristics for operating surfaces. All surfaces should be textured to have nonskid properties or have a nonskid coating applied. If night operations are contemplated, a light-colored surface is recommended to improve pilot depth perception. Treat the decking and supporting structure of a wood or metal load-distribution platform to make it weather-resistant.

Perimeter Protection Safety nets, guard rails, or fences should meet requirements of local or state building codes. Guard rails or fences should not penetrate heliport primary, approach, or transitional surfaces nor should the installation create an actual or perceived psychological obstacle to pilots using the heliport. A safety net, Fig. 7, is recommended for touchdown pads raised above the level of the roof. These nets should be located below, and not rise above, the plane of the heliport primary surface. A net width of at least 5 ft (1.5 m) is recommended.

Surface Drainage The takeoff and landing area should be designed with gutters that would isolate the runoff of any spilled liquids. It is essential that these liquids be prevented from discharging into the building's drainage system. Local building codes should be reviewed to determine whether the proposed collection system complies with the applicable code provisions.

Structural Implications The surface used for takeoffs and landings on elevated heliports should be an integral part of the building's design whether it is incorporated as a roof-level or plat-

NOTE: Platform heliports shall have two entry-exit points. The heliport perimeter lights and safety net should not project above the level of the touchdown pad.

Fig. 7 Platform heliport showing lighting and safety net.

form facility. The actual landing surface should be constructed of materials that will not yield under hard landings. However, the heliport designer may take advantage of any energy-absorbing properties inherent in roof-decking materials or structural-framing techniques. Design loads other than those applied by the helicopter, such as snow, rainfall, wind, passengers and cargo, flight-supporting equipment, additional weight of the heliport, etc., should be calculated in accordance with applicable building codes. An analysis of this magnitude requires the professional services of a qualified architect or engineer. Proponents of elevated heliports should consider the probability of future operations by larger helicopters when designing the facility.

Marking and Lighting The basic marking and lighting for an elevated heliport are identical to that of a comparable ground-level facility.

Marking An elevated heliport may be subject to an operational weight limitation. A red numeral on a white square is recommended to convey this information to the pilot of the approaching helicopter. The number indicates the helicopter gross weight the facility is capable of supporting.

Lighting Because an elevated heliport takeoff and landing surface is likely to be size-limited, perimeter lights may be installed on supports extending beyond the edge of the touchdown pad. (See Fig. 7.) Perimeter lights should be at or only slightly above the level of the touchdown pad. Under some conditions, a floodlighted touchdown pad with reflective markings may be acceptable as an alternative to perimeter lighting. Elevated heliport lighting plans should be discussed with the appropriate FAA Airports office. The recommended heliport beacon may be mounted on the

same or on an adjacent building as conditions dictate.

Fire Protection Requirements for elevated and rooftop heliport fire protection are contained in the National Fire Protection Association's Booklet 418 (1973). These requirements are set out in Table 3. When local fire codes are more restrictive, the local code shall prevail. Personnel engaged in heliport operations should be instructed in the proper use of installed firefighting systems. The design, installation, and periodic performance testing of fire protection systems should be carried out by qualified persons.

TABLE 3 NFPA Recommendations for Heliport Fire Protection—Rooftop Heliports (NFPA-418, 1973 Edition)†

Heliport category	Water for foam production using protein or fluoroprotein foam concentrates††				Foam-compatible dry chemical (rating)*	Additional water for foam if heliport is elevated	
	Amount of water		Total rate of discharge			Gallons	Liters
	Gallons	Liters	Gpm	Liters			
H-1	None**	None**	None**	None**	2-80B:C Extinguishers	None**	None**
H-2	500†	1,900†	100	380	2-80B:C Extinguishers or 1-160B:C Wheeled Extinguisher	1000†	3,800†
H-3	1500†	5,700†	200 from two 100 gpm nozzles or from one mobile unit with a turret	760	2-80B:C Extinguishers and 1-160B:C Wheeled Extinguisher	1500†	5,700†

* See Standard on Installation of Portable Fire Extinguishers (NFPA No. 10; ANSI Z112.1).

** Many times a water supply meeting the suggestions for Category H-2 may be readily available. In such cases it should be made available assuming personnel are available to utilize the equipment in event of an emergency.

† This amount of water should be immediately available from a hydrant (standpipe), pressurized tank, reservoir, or mobile vehicle so that it can be dispensed at the rates indicated and at a satisfactory pressure. Additional water should be available to provide a continuing rescue and fire fighting capability wherever feasible.

†† The quantity of water may be reduced one-third when aqueous film-forming foam concentrate is used.

‡ Deviations and/or equivalent substitutions may be authorized by competent authority to comply with local fire codes or to meet unusual site or operational conditions.

DESIGN CRITERIA

General

During the process of developing these design criteria, certain assumptions had to be made because of the lack of commitment of large STOL aircraft to civil production. Therefore, these standards represent considered judgment of what constitutes a practical set of criteria considering available data, safety, noise, environment, and economics. It is apparent that the shorter the runway the easier it will be to locate a STOL port site, and the greater will be its compatibility with the local environment. On the other hand, the criteria cannot be so restrictive that aircraft manufacturers will be unable to produce a vehicle which can operate safely and economically from the STOL port.

Design Criteria

The following criteria have been developed based on STOL aircraft, bidirectional runway operations, and a precision instrument approach. See Figs. 1 and 2 and Table 1 for illustration of specific dimensions.

Runway Length Determination

A discussion of takeoff and landing runway lengths is needed to establish a common understanding of the terms used. This is particularly necessary for the case of the elevated STOL port, where reference to Federal Aviation Regulations (FAR) field length cannot be considered in the same context as the conventional airport.

Microwave ILS

Microwave instrument landing systems for STOL operation are currently being evaluated

by the FAA. The type of equipment has been designed specifically for steep gradient approaches. The siting of the microwave system may be relatively simple since the localizer and glide slope functions may be collocated. (See Fig. 1.) Offset instrument landing system (ILS) approaches would be advantageous under certain site conditions and are under study. Nevertheless, an offset approach should be considered only where obstructions in the approach would prevent a straight-in ILS procedure.

Obstruction Clearance

The imaginary surfaces for protection of the STOL port are shown in Fig. 3.

General The surfaces have been defined on the basis of operational tests with the microwave ILS. The 15:1 slope for the approach/departure surface is predicated on adequate obstruction clearance for steep gradient approaches and also for takeoff climb.

Curved Paths For VFR (visual flight rules) operations, a curved path for approach or departure is quite practical and may be necessary in some cases to provide a suitable route. For example, an IFR (instrument flight rules) procedure may be feasible from only one direction. Under adverse wind conditions, it would be desirable and perhaps necessary to complete the IFR approach, transition to VFR and land from the opposite direction. The radius of the curved path will vary according to the performance of individual aircraft and the angle of bank used. For planning purposes, a radius of 1,500 ft may be used.

Runway Orientation

One of the primary factors influencing runway orientation is wind. Ideally, the runway should be aligned with the prevailing winds. It is recognized that the limited number of STOL port sites will minimize the opportunity for the runway to have optimum wind coverage. On the

other hand, it is also recognized that the availability of a crosswind runway on a metropolitan STOL port will be rare. Accordingly, the designer should attempt to obtain maximum wind coverage. The minimum desirable wind coverage is 95 percent based on the total hours of available weather observations. In other words, the objective is to attain more than 95 percent usability (preferably 98 percent). The allowable crosswind component will be determined by the crosswind capabilities of the most critical aircraft expected to operate at the STOL port.

Parallel Runways—STOL Port

For simultaneous VFR operations on a STOL port, the minimum separation between the centerlines of parallel runways should be 700 ft.

Runway Capacity

The capacity of a runway is the number of aircraft operations (landings and takeoffs) that the runway can accommodate in a limited period of time. The operational capacity of a STOL runway will be lowest during IFR conditions. To obtain maximum IFR capacity, the STOL runway should be equipped with a microwave ILS and radar surveillance (including an air traffic control tower). A method for calculation of capacity values is given in Advisory Circular 150/5060-1A. This publication discusses the numerous factors which must be considered in a capacity analysis. However, as a general guideline, with current procedures, the IFR capacity of a single STOL runway will be approximately 45 operations per hour. It is expected that this capacity will be considerably expanded when adequate data have been collected and analyzed.

Potential Configurations

In many metropolitan areas, siting of a STOL port may necessitate an elevated structure. At such sites, the designer should strive to achieve vertical loading and unloading of pas-

TABLE 1 Design Criteria for Metropolitan STOL Ports*

Design item	Recommended criteria	Comment
Runway length at sea level and 90°F	1,500 to 1,800 ft	Correction for elevation and temperature to be made on the basis of individual aircraft performance.
Runway width	100 ft	Widening may be desirable if wind coverage is less than 95 per cent.
Runway safety area width	200 ft	Widening may be desirable if wind coverage is less than 95 per cent. If elevated, a 300-ft width is recommended for the structure.
Runway safety area length	1,700 to 2,000 ft	If elevated, the structure would be within this range.
Taxiway width	60 ft	Based on expected configuration of second generation aircraft.
Runway C_L to taxiway C_L †	200 ft	Based on expected configuration of second generation aircraft.
Runway C_L to edge of parked aircraft	250 ft	Based on expected configuration of second generation aircraft.
Runway C_L to building line	300 ft	Height controlled by transitional surface.
Taxiway C_L to fixed obstacle	100 ft	Based on second generation aircraft.
Runway C_L to holding line	150 ft	Based on second generation aircraft.
Separation between parallel runways		See text.
Protection surfaces:		
Primary surface length	Runway length plus 100 ft on each end	
Primary surface width	300 ft	Based on the use of microwave instrument approach equipment.
Approach/departure surface length	10,000 ft	
Approach/departure surface slope	15:1	
Approach/departure surface width at:		
Beginning	300 ft	Approach/departure surface is 765 ft wide at 1,500 ft from beginning.
10,000 feet	3,400 ft	
Transitional surface slope	4:1	
Transitional surface maximum height	100 ft	
Clear zone:		
Length	750 ft	Begins at end of primary surface.
Inner width	300 ft	
Outer width	532 ft	
Pavement strength	150,000 lb gross weight on dual tandem gear	Based on second generation aircraft. Also see paragraph headed "Structural Design."

* The criteria are subject to change as further experience is gained.
† C_L = centerline

sengers and cargo; i.e., from one level to another. Such a design will allow an operational area that is virtually free of fixed obstacles. Each STOL port should be designed with due consideration of local conditions, particularly the configuration of the land available and surrounding land uses. Figure 4 shows one possible layout of the staggered runway concept. One runway is used primarily for landing and the other for takeoff. This configuration allows a considerable reduction in the total operational area by eliminating parallel taxiways. Also, the flow of traffic is optimized, since no aircraft backout or turning around is involved. Figure 5 shows the tandem runway concept. Again, one runway is used for

landing and the other for takeoff, but not simultaneously. Spacing must be provided for taxiing past parked aircraft and aircraft backout for turning around. The figures are intended to illustrate the new approach which must be taken in the planning and design of STOL ports; they are not intended to require a parallel runway configuration.

ELEVATED STOL PORTS

General

The siting of a STOL port involves a series of tradeoffs. One of these is the optimum site for the origin/destination of passengers versus

availability of a practical and economic site. In metropolitan areas, this causes a detailed look at elevated STOL ports. For example, in New York City, several waterfront sites on Manhattan Island have been studied. In Los Angeles and San Francisco, sites have been analyzed over railroad yards. All are intended to provide air transportation integrated with surface transportation. Such a facility appears to have a great potential for accommodating the short-haul air passenger demand. However, since it is elevated, there are some unique design problems which must be recognized.

Operational Surface

Essentially, the same standards are used for elevated STOL ports as surface facilities. Nevertheless, the question arises as to what is the recommended minimum.

Length of Structure The length of structure recommended is a range between 1,700 and 2,000 ft.

Width of Structure The recommended width of the structure is 300 ft for the runway operational area. However, this is dependent upon the emergency arresting system selected for lateral containment, the degree of wind cover-

Fig. 4 Potential layout.

Fig. 5 Potential layout.

age, and the need for a parallel taxiway. The lateral arresting system may require a greater or lesser area width, adjacent to the runway. Also, if the runway is not aligned with prevailing winds, it may be appropriate to have a wider runway. For most STOL ports, a parallel taxiway will be needed. In this case, the structure should be at least 400 ft wide.

Structural Design

The landing area should be designed for the largest aircraft expected to use it. The maximum weight aircraft anticipated by 1985 is 150,000 lb. Other types of loads, such as snow, freight equipment, etc., should be considered in the design of the area and the structures as appropriate.

Emergency Equipment

Provision should be made for equipment on the operational area to handle emergency medical and fire situations. Consideration should also be given to some type of built-in hydrant system.

Aircraft Maintenance and Fueling

Due to the limited parking space available, it appears logical to plan only for emergency maintenance. The decision to install an aircraft fueling system will depend on several factors, among which is the requirement of the local building code.

Floating STOL Port

A STOL port located on water (floating or semi-submersed) is not truly an elevated facility.

However, many of the operational problems associated with a floating STOL port are the same as for an elevated STOL port. For example, emergency arresting systems should be provided to ensure that the aircraft does not fall into the water. On the other hand, wind flow should be considerably less of a problem. In many metropolitan areas, a floating facility, on either an interim or permanent basis, may provide the best solution to establishing STOL service.

TERMINAL AREA

General

The primary purpose of the terminal area on a STOL port is the same as the terminal area on a conventional airport—to provide for the transfer of passengers and cargo from one mode of transportation to another. However, due to the specialized function of the STOL system, attention should be given to possible innovations in the terminal area, such as gate processing and vertical movement of passengers. The STOL system, which is aimed at short-haul, high-density air transportation, must be efficient in every aspect.

Terminal Building

The terminal building should be designed to accommodate a steady flow of passengers rather than long-term holding of passengers. This means secondary features of the terminal, such as concessions and eating facilities, should be minimized. To aid in efficient passenger handling, consideration should be given to passenger processing at the gate. Since the majority of short-haul passengers are business-

oriented, time-conscious, and carry relatively little baggage, gate processing should be quite feasible. Also, mutual-use (or common use) gates appear to be a requirement.

Vertical Movement

On elevated STOL ports, it may not be feasible to locate the terminal on the same level as the operational area. This would, of course, require vertical movement of passengers and baggage. Several methods of accomplishing this have been studied. Among these are escalators, elevators, and loading bridges. The escalators would involve the least cost but would create a fixed obstacle in the aircraft maneuvering area. The elevators can be located on the side of the structure but are expensive and preclude a steady flow of passengers to the aircraft. The loading bridges completely protect the passenger from the weather but are expensive and create an obstacle. At surface STOL ports, vertical movement of passengers may be feasible between mass transit vehicles and the aircraft gate area. This should be given careful evaluation during the initial planning of the terminal.

Capacity

The size of the terminal is determined by the peak-hour volume of passengers and cargo. The forecast of the peak-hour volume must be made recognizing the maximum capacity of the runway (in VFR conditions), the aircraft passenger capacity, the aircraft load factor, and the frequency of service. Further, an analysis must be made of the maximum capacity of the surface access systems. Surface congestion has a direct effect on the efficiency of the air transportation system.

SITE SELECTION

Water Areas

In selecting an adequate site within the areas deemed feasible for water flying, it will be necessary to choose one having the proper water-area dimensions, depth, and approach or glide path ratio for the types of planes to be accommodated. Table 1 shows by comparative groups the recommended minimum standards for water landing areas. Generally, most localities will not be concerned with lengths of water areas of 5,000 ft or more. Larger installations are primarily for large commercial aircraft and military operations.

Prevailing Winds The direction and velocity of prevailing winds over the surface of the water will be the controlling factor in determining the direction of water lanes. It is not necessary to consider winds of 3 mph or less when making these determinations.

When the water landing area consists of a single lane (covering two wind directions) the greatest percentage of wind coverage should be obtained. In many cases these single-lane operating areas cannot be oriented to take maximum advantage of the prevailing winds. In this regard, a shifting of the direction of the water lane should be effected so as to utilize the greatest possible wind coverage in conjunction with water currents and approach conditions. The influence of approach zones and currents is explained under these two respective headings that follow. Where all-way landings and takeoffs can be provided, a study of the wind conditions will indicate the primary and secondary water-lane directions.

Approach Zones For seaplane operations the ideal approach zone is one which permits unobstructed approaches over water at a ratio of 40:1 or flatter, with ample clearance on either side of the approach zone center line. The width of the zone should increase from the ends of the water lanes so that at a distance of 1 mi from the end of the water lane, the zone is approximately the width of the water lane plus 1,000 ft.

Under favorable temperature conditions a water-borne aircraft will leave the water and fly level for approximately 4 seconds and a distance of about 400 ft before starting to climb. The rate of climb after this 4 second period is about 20:1. Where commercial operations are anticipated, it is recommended that the approach angle should be 40:1 or flatter.

The approach zones should be over water wherever possible, thereby permitting a reasonably safe landing in the event of power failure during initial climb or landing approach. Furthermore, for obvious safety reasons, climbs and approaches should not be made over populated areas, beaches and similar shore developments. Apart from the all-im-

portant safety factors involved, such maneuvers can create ill will and antagonism on the part of local inhabitants and boating interests. Where a suitable water area exists and the shore and surrounding development prohibits straight-away approach zones, it may be possible to establish operations in which an over-water climbing turn or let-down procedure is used.

Currents and Water-Level Variations Current and changes in water level usually will not be great enough to cause construction or operational difficulties. Only under extraordinary conditions will currents affect size requirements of the water landing area. Landing and takeoff operations can be conducted in water currents in excess of 6 knots (7 mph) but any taxiing operation between the water lanes and the shore facilities will usually require the assistance of a surface craft. Currents in excess of 3 knots (3.5 mph) usually cause some difficulty in handling seaplanes, particularly in slow taxiing while approaching floating docks, or in beaching operations. In some cases undesirable currents may be offset to some extent by advantageous prevailing winds. Locations of the following types should be avoided: (1) Where the currents exceed 6 knots (7 mph); (2) where unusual water turbulence is caused by a sharp bend in a river, the confluence of two currents, or where tide rips are prevalent.

As a general rule if the change in water levels exceeds 18 in., it will be necessary to utilize floating structures or moderately inclined beaching accommodations to facilitate handling of aircraft at the shoreline or water front. Where water-level variations are in excess of 6 ft, special or extended developments

to accommodate the aircraft must be made. These developments might require a dredged channel, extended piers or special hoisting equipment depending upon the slope of the shore. It follows that the greater the water variation, the more extensive will be the facility requirements.

Water-Surface Conditions Open or unprotected water-operating areas may become so rough under certain conditions of winds and currents as to prohibit operations; hence, the varying water conditions at the proposed site must be investigated. The average light plane (3,000 lb or less), equipped with twin floats, can be operated safely in seas running to about 15 in. measured from crest to trough, while 18-in. seas will restrict normal safe operations of these aircraft. Larger float-equipped or hull-type aircraft ranging in weight from 3,000 to 15,000 lb can generally be operated safely in seas running as high as 2 ft measured from crest to trough. At the other extreme, smooth or dead calm water is undesirable because of the difficulty experienced in lifting the floats or hull from the water during takeoff. The most desirable conditions exist when the surface of the water is moderately disturbed, having ripples or waves approximately 3 to 6 in. high. Locations at which excessive ground-swell action may be encountered should be given careful consideration to determine the effect of such action on the intended operations.

Another consideration which must be taken into account, when examining the water conditions, is the presence of floating debris. Areas in which there is an objectionable amount of debris for considerable periods of time should be avoided.

TABLE 1. Recommended Minimum Standards for Water Landing Areas*

Minimum length in feet (sea level)	Minimum width in feet	Minimum depth in feet	Turning basin in feet-diameter	Remarks
2,500	200	3	None	Minimum for limited small float plane operation. Approaches should be 20:1 or flatter for a distance of at least 2 mi.
3,500	300	4	None	Minimum for limited commercial operation. Approaches should be 40:1 or flatter for a distance of at least 2 mi.
5,000	500	10	1,000	Minimum for extensive commercial operation. Approaches should be 40:1 or flatter for a distance of at least 2 mi.
10,000	700	15	2,000	Unlimited. Approaches should be 50:1 or flatter for a distance of at least 2 mi.

* The lengths indicated above are for glassy water, no wind, sea level conditions at standard temperature of 59°F. The lengths shown will be increased at the rate of 7 percent for each 1,000 ft of elevation above sea level. This corrected length shall be further increased at the rate of one-half of 1 percent for each degree that the mean temperature of the hottest month of the year, averaged over a period of years, exceeds the standard temperature. See Fig. 1.

Sheltered Anchorage Areas A cove, small bay, or other protected area is desirable for use as a seaplane anchorage or mooring area in order to relieve floating-dock or onshore parking. A sheltered area that is protected from winds and currents is required, particularly if overnight or unattended tie-ups are to be made at locations where sudden and sometimes unexpected storms or squalls develop. Appreciable currents and winds in the anchorage area make the approach and picking up of a buoy more difficult and at times will call for the assistance of a boat. The anchorage area should be within sight and calling distance of the floating dock or ramp if possible. It also should be located so as to permit unrestricted maneuvering of the aircraft when approaching the buoys.

Bottom Conditions The type and condition of the bottom at the proposed seaplane-facility site can influence the arrangement of the various components thereof, the means of construction of the fixed structures, and the water operations to and from the shoreline.

Reservoirs and other artificial bodies of water often are flooded natural-land areas and frequently are not grubbed (stumps and logs removed) before flooding. This situation causes anchors and anchor lines to foul and, over a period of time, can create a hazard if these submerged objects rise to the surface and remain partially or totally submerged.

Obstructions which project from the bottom and constitute a hazard should be removed or, if this is impractical, must be suitably and conspicuously marked to indicate their presence to those utilizing the water area.

A hard bottom composed of shale or solid rock formations will make the construction of fixed offshore structures difficult and costly. Anchors also tend to drag over this type of bottom. Unless specially designed mooring anchors are used, precautions should be taken

by selecting a more suitable anchorage area. Where boulders are found on the bottom, some construction difficulties may be encountered and anchor lines may tend to foul. Mud bottoms ordinarily present little or no difficulty.

The Onshore Facility

No site for the onshore development should be given serious consideration until it is known that adequate room is available for all of the space-taking elements required. Determination of size will require a knowledge of (1) How many planes will need hangars or tie-down space; (2) how many car parking spaces will be necessary; (3) how many patrons will use the facility; (4) whether a small office will suffice or whether an administration building with facilities for eating, refreshments, and other nonaviation activities is required; (5) how much outdoor common space, such as for lawns, walks, terrace, etc., is needed. Answers to numbers 1 and 2 can be fairly accurately measured while 3, 4, and 5 will depend upon local conditions varying from a very simple installation, in remote recreation areas, to large installations in metropolitan areas. Minimum unit requirements are as follows:

Minimum Unit Requirements for a Single Onshore Facility

Item	Facility	Area, sq ft
1 plane.....	Hangar or tie-down space	3,000
1 car.....	Parking space	250
Office.....	Small building	80
Common outdoor space	Walks, lawn, or open space	20 percent of above total

To compute the number of square feet for a given facility, multiples of the above criteria

may be used. For example, a facility basing 15 aircraft in the water and 6 on land would need a maximum of 21 car-parking spaces (one for each plane) during maximum use period, plus one for each employee; i.e., approximately 25 cars or 6,250 sq ft of area. Hangar or tie-down space for 6 planes would occupy 18,000 sq ft. One small office building with food counter would require another 400 sq ft. Finally, the common outdoor use space would occupy about 4,930 sq ft (this figure representing 20 percent of the sum of the other areas). Accordingly, the total area would amount to about 29,580 sq ft or about seven-tenths of an acre.

In addition to being adequate in size, the shore facility should be located reasonably close to the water-operating area to eliminate long taxiing operations.

The availability of utilities such as electricity, water, telephone and sewage should be investigated. The basic installation may not require all utilities, but water and sanitary facilities of some sort should be provided for at all locations. In remote rural areas, established water lines and sewerage facilities will be out of the question. If such is the case, well water and chemical toilet units are feasible. State or local sanitary codes must be respected when it is planned to install water and sanitary facilities of this nature.

The most desirable sites have a moderately sloping shoreline and a water depth suitable to permit aircraft taxiing operations as close to the shoreline as possible. Excessive fluctuations in water level are not desirable since this condition requires expensive shoreline installations. Care should be taken to determine whether the water level offshore will permit aircraft operations when the water level is low.

In all cases, the area for a seaplane facility should be sufficient in extent to form a complete unit without any interior private holdings

Fig. 1 Effect of elevation and temperature on water-lane lengths.

SEAPLANE TERMINALS

and with good boundary alignment for complete land utilization and protection. It may also be desirable in some cases to secure a liberal setback from the highway in order to protect the project and adjacent property from noise and glare and to provide room for widening any highway paralleling the property line. If sufficient land is available, a greenbelt all around the project will enhance the desirability of a seaplane facility in a neighborhood area.

General Planning Considerations

Having determined the best site available from the aeronautical point of view, other elements of community, county and state planning should be considered. These elements are accessibility and land use.

Accessibility Probably the most obvious consideration influencing the location of a seaplane facility is its proximity to the ultimate destination and source of the users. The ability of the airplane to cover long distances in a short space of time often is cited as its outstanding attribute. To retain this advantage, every effort should be made to locate the facility convenient to good streets and rapid or mass transportation facilities in urban areas, and to major highways or good roads in rural areas. Utilization of speedboats and other surface water transportation should also be carefully explored. If these associated means of access and transportation are overlooked, minimum use of the facility can be expected. In rural or recreation areas where the seaplane is used primarily for sport, location of the facility with regard to access will not be a serious problem except that the means of access or transportation for fuel, repairs, and supplies must be adequate.

Land Use Locating a facility in a residential neighborhood where let-down and takeoff procedures occur over homes may be a source of annoyance to residents in the area. Unless flight traffic procedures can be developed which will eliminate the objection of takeoffs and landings of this nature, the planner should seek a location where the existing land use will be benefited by seaplane activities. Personal seaplane flying is desired in certain neighborhoods where boating and seaplaning are of mutual interest. Here the seaplane facility will be as much an asset to the community as a yacht club. The onshore development might well include a combination office and club house for seaplane and boating interests. Normally there will be little use for a personal seaplane facility in an industrial area where local truck and auto traffic congestion make access time-consuming and undesirable.

Every effort should be made to recognize existing conditions and future proposals so that the seaplane facility can take its proper place in the community.

DESIGN CONSIDERATIONS

The Water-operating Area

Most natural water areas will provide, without modification, the required dimensions necessary for seaplane operations. Where the available water area is limited, the minimum water-operating area must consist of one water lane for landings and takeoffs and a taxi channel. A turning basin will be necessary in cases where turning must be confined to a restricted area because of water depth requirements or

Fig. 2 General operating area.

for the segregation of other water surface-craft activities. In some cases anchorage areas may be necessary.

Water Lanes Minimum dimensions of water lanes necessary for seaplane operations are set forth in Table 1. Inasmuch as elevation and temperature affect water-lane length requirements, these factors must be considered and the lengths adjusted accordingly. Figure 1 presents a chart showing the effects of these factors on certain basic lengths. A typical layout for a single water-lane operating area is shown in Fig. 2.

Taxi Channel For small seaplanes the taxi channel should have a minimum width of 125 ft, although a width of 150 ft or more is preferred. These channels should be located to provide direct access to the onshore facility and when possible should be so oriented that approach to the ramp or floats will be into the prevailing wind. They should provide a minimum of 50 ft clearance between the side of the channel and the nearest obstruction.

Turning Basins Turning basins will be required where the use of water area is restricted. A minimum radius of 125 ft should be available for surface turns. These turning basins should be located at both ends of the water lanes and adjacent to the shoreline area. The same minimum clearance criteria, i.e., 50 ft, should be used for the separation between the side of the turning basin and the nearest obstruction.

Anchorage Areas Where anchorage areas are required, they should be located so as to provide maximum protection from high winds and rough water. The space requirements for an anchored aircraft, and the number and size of aircraft to be accommodated, will determine the size of the anchorage area. Each aircraft will swing around the mooring while anchored. To determine space needed, one must know the wingspan and length of aircraft, the length of line and bridle, and the lowest water level. The length of anchor line should be at least six times the maximum depth at mean high water at the anchor location. In cases where the aircraft swing space is limited, the length of the anchor line may be shortened to not less than three times the high-water depth, provided the normal anchor weight or holding capacity is doubled. Short anchor lines cause hard riding and should not be used where

swells or heavy wakes from boats are common. Center-to-center spacing of anchors, where small twin-float aircraft are to be moored, should not be less than twice the length of the longest anchor line plus 125 ft. For larger types of aircraft, including flying boats and amphibians this spacing should be increased by an additional 100 ft. A general layout of anchorages is shown in Fig. 3.

The Shoreline Area

Shoreline installations are partly on land and in the water. They are required to perform two general functions: (1) to provide servicing, loading and unloading, handling and tie-up facilities for seaplanes without removing them from the water, and (2) to provide haul-out facilities for removing seaplanes from the water.

The types, size, and arrangement of these installations will be determined by water conditions, the topography of the land adjacent to the water, the configuration of the bottom of the water area, the number and type of planes to be docked or removed from the water, and wind conditions. The installation will vary from a simple wood-plank platform to the more elaborate ramps with railway facilities, piers, and floats.

Ramps The simplest form of ramp consists of a wood-plank platform approximately 15 by 20 ft, laid on a sloping shore, with half its length in water. A device such as this will allow a small float plane to taxi up and out of the water. The use of such a ramp is predicated upon a relatively constant water level and the shore slope no steeper than 8 to 1.

The slope of any ramp should not be greater than 7 to 1, with gradual slopes down to 10 to 1 being preferred. Slopes less than 10 to 1 usually are too long and hence costly to construct.

Figure 4 shows the maximum draft of seaplanes of various weights and types. These data are useful in determining the depth to which the submerged end of a ramp must be lowered. A depth of ramp toe of 4 ft will provide sufficient depth for most types of waterborne aircraft in use today; a depth of 3 ft will permit handling of all but the heaviest type of amphibians. For small, light, float planes a depth of about 18 in. is adequate. In all cases, this dimension should be established for mean low water.

A ramp width of 15 ft is the minimum for small twin-float or amphibian aircraft opera-

Fig. 3 General layout of anchorage areas.

tions when the water and wind conditions are relatively calm. By adding 5 ft to this minimum width, practically all water-borne aircraft of gross weights up to approximately 15,000 lb can be handled with safety, and pilots of small seaplanes can make an unattended ramp approach under adverse conditions. In figuring the ramp width, the outside-to-outside float dimensions of twin-float aircraft and the treads of amphibian aircraft are important factors and for reference are shown in Fig. 4. The maximum dimension—based on the largest aircraft to be accommodated—plus additional space on either side to allow for drift when approaching, and safe working space for personnel

when handling an aircraft on the ramp, determines the minimum practical width. Ramp-width determination does not necessitate consideration of wheel tread of present-day float plane dollies. Normally, the dolly wheels are spaced to fall between the floats, and in cases where the wheels are outside, the tread is 16 ft or less.

Piers Piers or fixed over-water structures can be utilized where the variation in water level is 18 in. or less. The pier should extend into the water to a point where the water depth is adequate for the types of aircraft to be handled. The usual design for a pier incorporates an

access walk approximately 5 ft in width with hand railings on both sides and an open-decked handling area approximately 30 by 50 ft at the walk's end. An open-decked area of this size will provide tie-up space for four small or three large seaplanes. On long piers, where the walking distance is too great for convenient handling of service equipment, a small storage shed may be located near the open-decked area. Fueling and lubrication facilities should also be located at the end of the pier.

Floats and Gangways Floats offer the greatest flexibility in providing docking facilities. This type of unit rides with wave action and is equal-

Fig. 4 Water-borne aircraft dimensional data by aircraft weight groups.

SEAPLANE TERMINALS

ly satisfactory in areas of great or negligible water-level variations. Universal action must be provided in anchoring or attaching floats together. Figure 5 shows various types of floats for docking. A float which provides an unobstructed wing clearance of 17 ft will permit practically any twin-float seaplane or small amphibian aircraft to come along its side safely.

Floats are usually connected to the shore or pier by booms and a gangway. The maximum water-level variation dictates the length of the gangway. In no case should gangways be less than 15 ft in length and should be at least 5 ft in width. Hand rails, preferably on both sides, should be provided to assist persons using the way. A 2.75 : 1 slope ratio is the maximum

for safe and easy walking and to prevent the handrails from becoming an obstruction to wings.

In some locations it may be desirable to anchor the float offshore with anchors and anchor lines with connection to the shore by a floating walkway. A floating walkway 5 ft or less in width must have outriggers spaced longitudinally approximately every 10 ft. Outriggers 8 to 10 ft long will prevent excessive rolling of the walk.

Spacing The desired clearances between the various docking units and ramps obviously will have a decided influence on their arrangement and location. Each docking unit should

be so located that an aircraft may approach and tie up in any one of the units when adjacent units are occupied. When aircraft are operated between the various units under their own power, the recommended minimum separation between the near faces of piers, floats, ramps or marine railway is 50 ft because a water-borne aircraft can normally be taxied safely past obstructions as close as about one half of its wing span. Where aircraft are moved between units by hand, the separation between the units may be less than 50 ft to facilitate handling. A minimum of 100 ft of unobstructed water should be available directly offshore from a ramp in the direction from which approaches normally will be made.

Floating Barges The lease or purchase of land for a seaplane-facility site may be a problem at some desirable locations and yet pier or gangway rights may be easily obtained. At such locations a floating barge, anchored offshore, makes an excellent facility. An office, lounge, and service shop can be included "aboard" and by adding a floating dock alongside and ramps at the ends, a very practical and efficient facility results. The floating barge may be anchored direct to the shore or a pier by booms and a gangway, or anchored offshore in a fixed position. Some operators prefer to allow the barge to drift downwind or down-water from a single anchor. Boat transportation will be needed if the unit is mobile and moored offshore. The very uniqueness of this type of installation will, in some localities, attract many persons otherwise not directly interested in water flying. The possibility of organizing this activity on a club basis should not be overlooked. This type of installation can be made more attractive by appropriate use of paint, colorful deck chairs, awnings, marine appointments, and recreation facilities.

Some units are in operation today where an entire barge is floating but is attached to the shore. Large logs are decked over and form the base for the entire structure, which is in some cases 150 ft long by 100 ft wide, in a series of flexible units.

The Service, Tie-down, and Storage Area

This element will occupy more space than any other onshore facility. For safety and convenience, it should be separated from other incidental activities on the site, either by adequate buffer space, fencing, or both. Every effort should be made to locate floating docks and piers so that access to them by the public will not require crossing the apron or hangar area. (See Fig. 6.)

Hangars Both storage and repair hangars should be located so as to permit the off-site delivery of repair material and use by service personnel over a route as direct as possible and without interference with the movement of aircraft. The service and storage hangar area should be located in such a position in relation to the ramp or marine railway that aircraft may be moved there as directly as possible, with the least possible amount of disturbance to tied down aircraft or aircraft already in repair parking spaces.

The amount of space required for apron tie-down and hangar facilities will depend upon the number and types of aircraft that are to be accommodated. Dimensions of various aircraft are shown in Fig. 4. This information can be used to determine the space required for taxiing, turning, and storing.

Hangars should be located in an orderly and functional relation to haul-out and ramp facilities, and to eliminate as much noise and con-

Fig. 5 Various types and arrangements of floats.

SEAPLANE TERMINALS

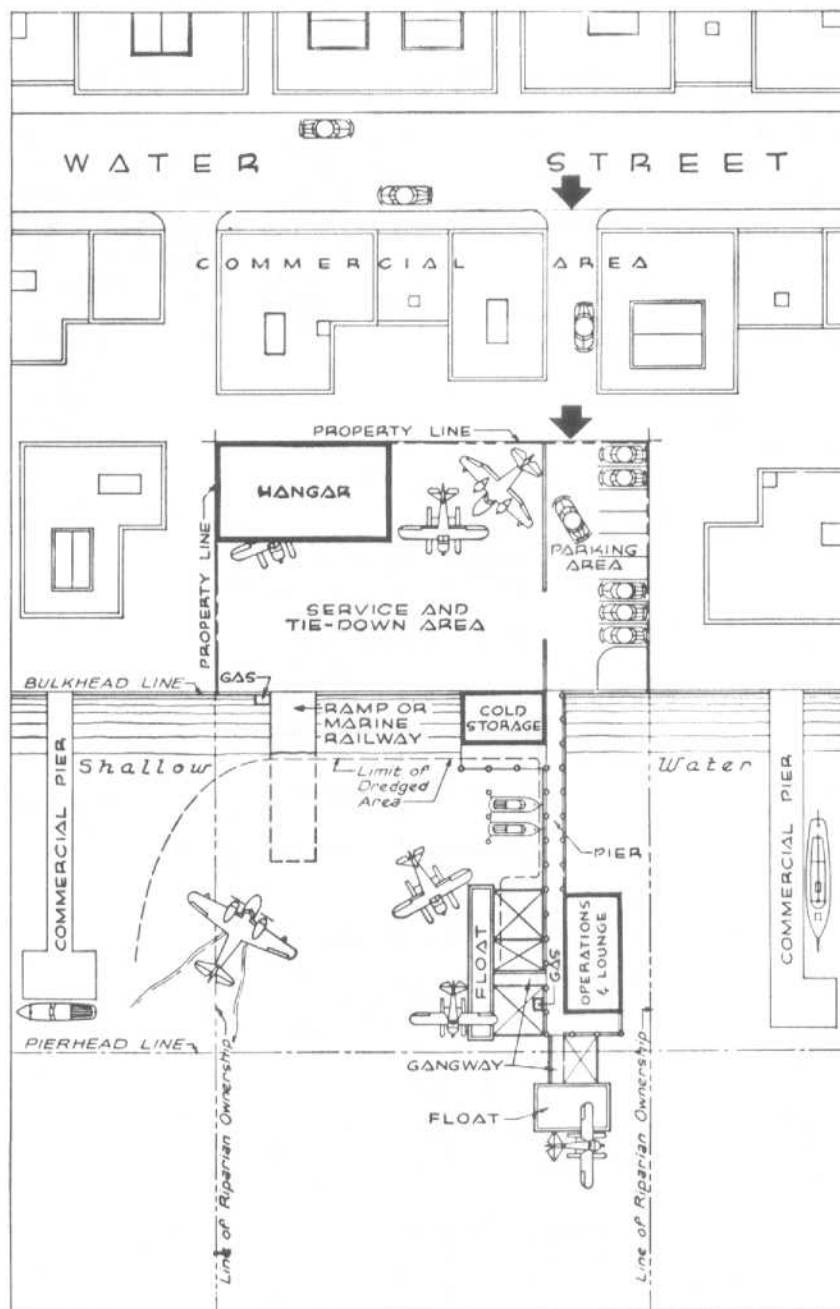

Fig. 8 Typical layout of onshore and shoreline development.

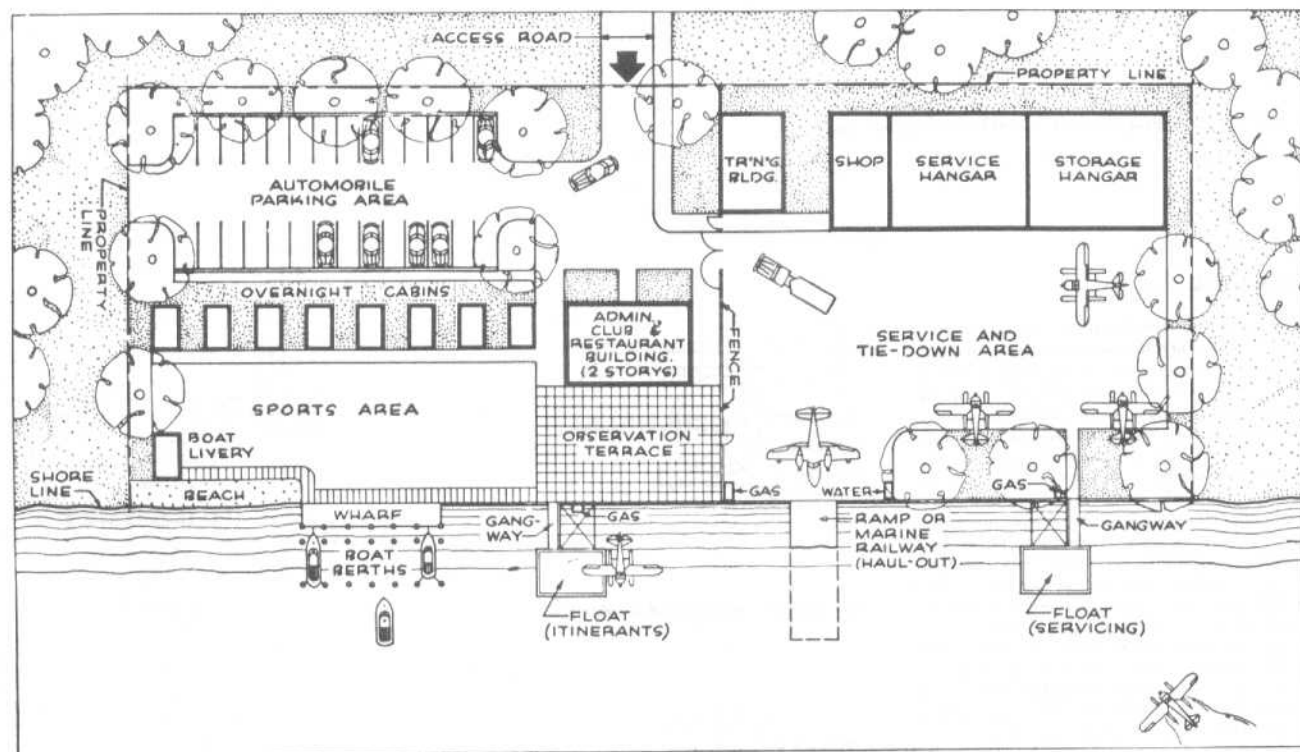

Fig. 9 Typical layout of onshore and shoreline development.

fusion as possible should be sufficiently separated from the administration building and common public-use areas.

The Administration Building and Common-Use Area

In simple installations, it may be necessary to utilize a hangar for both aircraft service and office space. In larger projects a separate administration building may be required to provide adequate space for the manager's office, passenger and pilot lounge, display space, restaurant or snack bar, and observation deck. A community room for public use, such as for lectures, meetings and classes should not be overlooked if needed. The building should not be oversized or monumental in character. Only a simple, functional design, adequate to take care of the estimated needs, is required. The location should be in a prominent position on the site, readily accessible to aircraft arrival and to customers and visitors from the onshore approach. Like airport administration buildings, visibility of the water area from the administration building is needed for the control of aircraft at locations where traffic in and out requires two-way radio communications.

Ample outdoor space reserved immediately adjacent to the administration building for public use is desirable. This space may consist of a small lawn or paved terrace on the water area side or, in more sizable installations, a larger section broken down into recreation areas, an outdoor dining terrace and lawn.

Access Access to the land area, both for customers and for service and delivery, should ordinarily be a two-way, all-weather road. However, when a long access road is required and the traffic to and from the facility is not sea-

sonal but relatively constant and without peaks, a one-way road will suffice. In such cases, turn-outs should be provided at convenient intervals. The plan should be designed for one traffic connection with the main highway or street, in order that its free-way may be preserved. A public highway should never be used as a part of the road system within a project if public use for through traffic is to continue after the project has been put into operation. Through traffic will unduly congest the land facility, could be hazardous to pedestrians, and splits the property into two separate units which is undesirable.

Roads Vehicular circulation must be provided for deliveries of gasoline, oil, fuel, and for refuse removal. These routes will influence walks and interior road system and to some extent the pattern of the master plan. In order to reduce development costs and maintenance, it is advisable to concentrate buildings for certain uses in areas with servicing facilities such as a service road, on one side. When topography and shape of tract are favorable, this type of plan effects economies.

Roads should be planned economically, but must be adequate in width to serve the anticipated traffic, to permit easy circulation and safe driving. In some instances, they may afford parking space on one or both sides, depending on the solution of a particular site problem. Some service roads may be desired for limited use. In such cases the entrance can be barred by removable posts or chains.

Parking Areas Provision of parking areas for cars must be made. As previously mentioned, one should allow one car for each based aircraft, one car for each employee, plus a ratio of visitors' cars commensurate with the judg-

ment of local interest in the use of the facility. An overall space of 250 sq ft of area will be required for each car. The type of parking space layout will, of course, depend upon the space and shape of the area available for the installation.

Parking areas should not be located so that pedestrians must cross a public road to reach the facility proper. This creates an unnecessary hazard, particularly to unescorted children who might dash across the public highway. Parking areas should be located convenient to the onshore and shoreline facilities. In no case should the pedestrians be required to walk a distance greater than 200 ft from the parking area or service road to reach buildings or shoreline.

Walks All walks should be laid out for direct access to and from the facilities to be reached. Like roads, they should not be oversized in the interest of economy of construction and maintenance. Recommended walks widths are:

Capacity	Width, ft
Public walk serving less than 100 persons	3
Normal standard walk	4
Walk serving over 400 person	5

All walks should clear obstructions (as planting, fences, etc.) by 2 ft. Avoid steps in walks; single risers should *never* be used in public walks. Avoid stepped ramps. A 10 to 15 percent gradient is preferred to steps.

Figures 7 to 9 show layouts on three distinctly different shapes of land area. These layouts indicate the inter-relationship of each use area. From arrangements such as these, studied in accordance with the previous discussion on the master plan elements and the general water-operating area shown in Fig. 2, the master plan is developed.

Transportation

BUS TERMINALS

By JULIUS PANERO, Architect and Planning Consultant

INTRODUCTION

The growth and development of bus transportation has closely followed advances in automotive technology and the improvement and expansion of the national highway network. The first bus routes were originated by individual entrepreneurs using converted passenger automobiles. These routes were short and service was generally unreliable. As the highway network expanded and more suitable bus equipment became available, these short, disconnected routes were merged into larger consolidated operations providing more reliable through services over longer distances. Our modern express highway system and the development of more comfortable and efficient high-speed buses have made bus transportation the leading means of public transport in the United States. Over the past decade bus services have evolved into several general operational categories and characteristic terminal types.

TERMINAL TYPES

Intercity Bus Terminal

The intercity terminal is usually found in the downtown core and is accessible directly by local transit, taxi, and auto. It differs from other terminal types in that it includes long-haul service in excess of several hundred miles and provides for a much greater number of bus movements. Land costs normally dictate vertical expansion capability in the denser city areas. (See Fig. 1.)

More elaborate "package express" facilities are provided in the intercity terminal and a greater amount of concession and rental space is provided to defray higher terminal construction and operating costs.

Airport-City Bus Terminal

The airport-city bus terminal provides primarily for the transportation of airline passengers from an urban center to the major airports it serves. Usually located in the urban center, the terminal is accessible by local transit systems, taxis, and autos. Oriented to departing and arriving flights, the terminal normally has provisions for arrival and departing flight information as well as preticketing and check-in facilities.

Urban-Suburban Commuter Terminal

This type of facility may be located within the downtown core, as a central passenger collection and distribution node, or on the periphery of the core, as a rapid transit feeder station. It is characterized by a diversified bus route structure and high-turnover commuter-type bus operations. Bus accessibility is an important consideration. Grade separated access by underpass or overpass connections and exclusive bus lanes on connecting highways are desirable to maintain schedule efficiency.

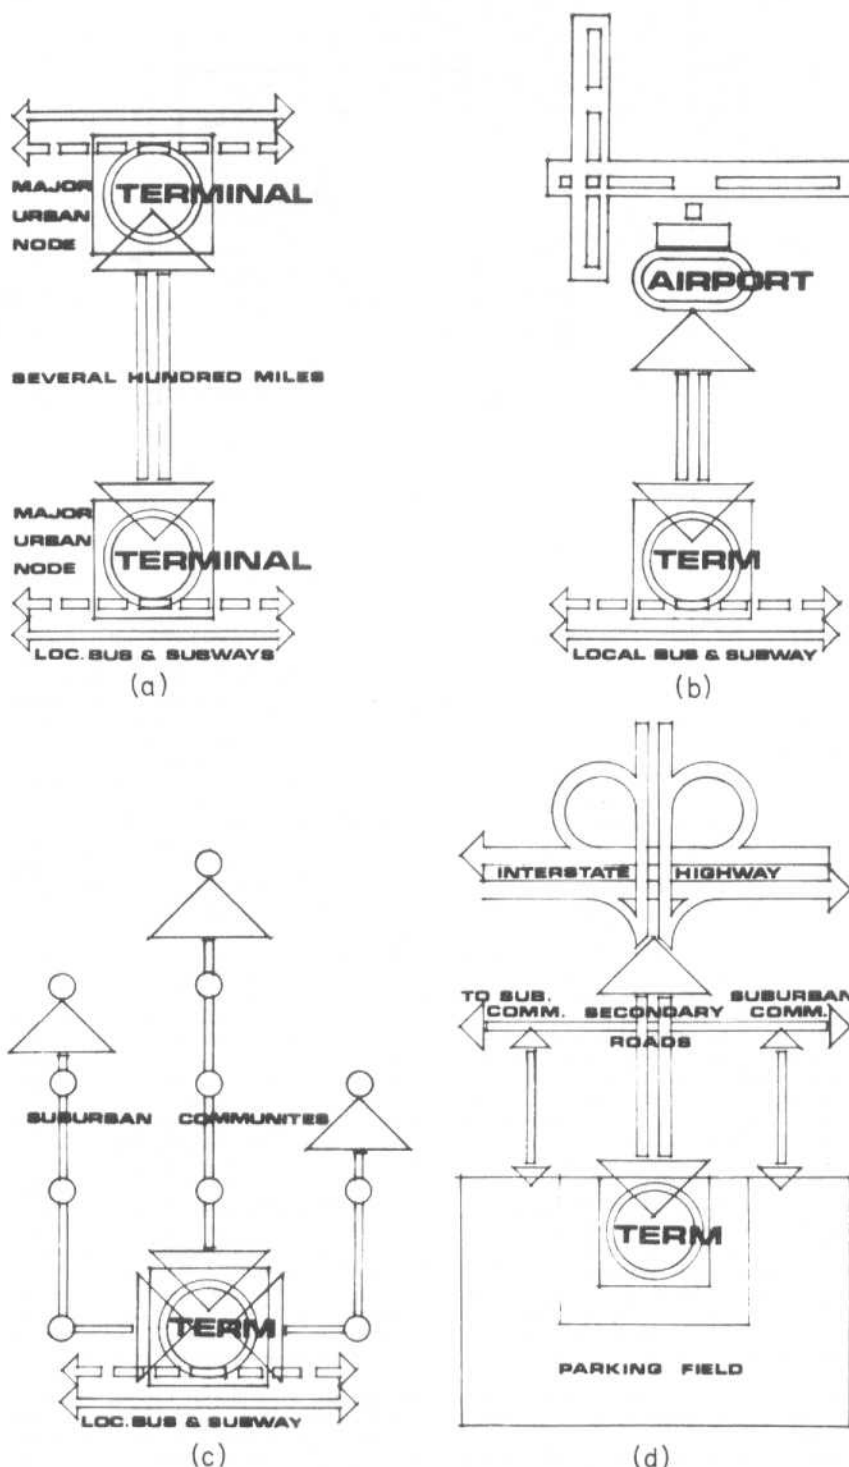

Fig. 1 Terminal types. (a) Urban located intercity terminal. (b) Airport-city bus terminal. (c) Urban-suburban commuter terminal. (d) Suburban-interstate terminal.

Suburban Interstate Terminal

The suburban interstate terminal is a peripheral type designed to avoid the traffic congestion and heavy investment associated with central city and/or airport terminal facilities.

The terminal is usually located adjacent to interstate highway connections with major cities or regional airports and in many instances serves the increasing outlying "urban sprawl" areas.

In an increasing number of cases terminals of this type serve a commuter-type function where the daily journey to work in the central city may take as long as 2 hours.

Sometimes referred to as "park and ride" terminals, because access is primarily by auto, these facilities are provided with open, paved parking spaces. Investment in waiting-room and bus-berthing facilities is minimal. The terminal is usually a one-story building of simple construction.

FUNCTIONAL ELEMENTS/PLANNING CRITERIA

General functional organization of the terminal is determined by site configuration, the volume and type of bus operations, and passenger and bus traffic circulation. Although all terminal types to some extent share common planning problems, there do exist some significant differences in design rationale.

One of the most complicated terminals is the intercity type, since it is often found in a dense, developed area in the heart of the central city and its general configuration is too often inhibited by existing construction and high land costs. Moreover, the underlying design rationale should maximize provisions for short lines of flow and communication between ticketing and baggage functions and the bus interface.

An island plan with the functional elements radiating from the core allows for maximum efficiency. Such a relationship would allow the "waiting" areas to serve as the central focal point, with all bus berth positions being equidistant. As the terminal becomes more linear in plan, functional elements begin to lose their cohesiveness and often require duplication.

Although the design of all terminal types is largely dictated by bus and passenger volumes, this consideration becomes even more significant in the design of high-volume commuter bus terminals.

In such facilities the design is controlled more by bus and passenger volumes, traffic circulation, and the resultant space demands for large numbers of bus berths, while baggage handling provisions are minimal or nonexistent. These space demands may dictate a vertical, multiple-bus-level solution, with intermediate passenger circulation concourses. Traffic access, by direct exclusive highways on the bus side and by feeder transit, auto, and taxis on the passenger side are important elements of this type of terminal.

Generally, with regard to the airport-city terminal, the primary planning considerations include provisions for efficient check-in facilities, baggage handling, and flight information. Moreover, counter space requirements are usually more extensive and should include weigh-in provisions and conveyors for handling of baggage. Adequate provisions should also be made for limousine, auto, and taxi access.

The suburban interstate terminal is perhaps the simplest of the terminal types. The most

Fig. 2 Flow diagram.

significant planning requirement is adequate provision for parking. Many, if not most of the passengers drive to the facility and park their cars until their return in the evening, while others may be driven to the facility and discharged. In many instances access to the terminal may also be via local bus service and taxi.

It is essential, therefore, that the parking facilities be located so as to minimize the walking distance to the terminal and that egress and ingress be planned to avoid traffic congestion along nearby arteries. If possible, some covered walkways should be provided leading from the parking field to the terminal building.

Since there will be movement of both vehicles and passengers at the same level, provisions must be made, for obvious safety reasons, to separate the two as much as possible.

Terminal requirements should include provisions for ticket sales, vending machines and/or small snack bar, toilet facilities, office, baggage and/or storeroom. (See Fig. 2.)

Space Requirements

Public Seating Seating in any of the terminal types may be provided in the form of a separate waiting room or, in a more open plan, in the form of a simple seating area within a larger public space. This function should be directly accessible to the concourse area and should be provided with drinking fountains, trash baskets, ash urns, and clocks.

The amount of public seating varies depending on individual circumstances, terminal type, and economic priorities. As a general rule of thumb, however, an allowance of one seat for every three passengers would be adequate for an intercity terminal. The passenger quantity is calculated by multiplying the number of loading berths by an average bus capacity of between 35 and 37 people. A 10-berth loading platform therefore, would result in terminal seating of between 117 to 124.

In a high-volume commuter terminal, seating accommodations may be reduced considerably since in-terminal waiting time is much less. This would also hold true for the suburban interstate terminal.

Ticketing Facilities The trend in ticketing facilities in the modern terminal, regardless of the type, is toward open counters in contrast

to the antiquated caged windows. In the larger intercity terminal, where more than one carrier may operate, separate self-contained glass-walled ticket offices may be provided, each housing their individual open ticket counters. The number of selling positions or agent stations varies with the individual operations policy of the carrier and the particular terminal type.

Perhaps the greatest number of selling positions are required in the intercity terminal. On the average, one position should be provided for each 25 to 30 waiting room seats. The lineal feet of counter space depends on individual carrier operation and the type of ticketing equipment used and may vary between 3 to 5 ft per position and/or about 50 to 60 sq ft per position. The height of the counter is usually 42 in.

In the airport-city terminal the ticketing facilities are usually in the form of continuous counters with a certain number of selling positions allocated to each airline. The length of each position is determined by the type of electronic equipment, TV equipment, and scales to be housed and usually varies between 4 to 5 ft.

Baggage Room Baggage room requirements vary significantly with terminal type and operation.

In the intercity terminal and the airport-city terminal, the baggage handling problem is more severe.

Ideally, in both cases, the sooner the departing passenger and his baggage are separated, the better. In the airport-city terminal this usually occurs at the ticket counter where the baggage is sent by conveyor directly to the loading platform or to a staging area or baggage room, where it remains before it is placed on board the bus.

In the intercity bus terminal the baggage is normally hand-carried directly onto the bus or to the baggage room, and from there it is placed on the bus. The baggage room should be accessible from both the public area and the concourse and have an area equal to about 10 percent of the total building or contain about 50 sq ft for each bus loading berth, whichever is higher. The baggage room should also be equipped with standard metal racks about four or five tiers high for baggage storage.

A portion of the baggage room may be used

Transportation

BUS TERMINALS

for a package express service, which and should function without interfering with concourse traffic. A separate package express counter should be provided. The length of the counter depends on the scope of the operation, which varies with each location.

Public Lockers and Telephones Lockers and telephones are revenue producing, and the quantities to be provided depend to a great degree on their potential earning capacity.

Dispatch Office The dispatch office controls all bus movement and consequently should be located on the concourse so that it can observe all loading berths. The size of the dispatch office may vary anywhere from 50 to 150 sq ft.

Offices All terminals regardless of type require a certain amount of office space. The specific area to be provided depends on the terminal size and type. Although usually offices for the terminal manager, passenger agent, and switchboard are sufficient, in larger terminals more elaborate facilities are required.

Rental Space The amount of rental space to be provided for stores, shops, concessions, etc., depends primarily on the earning potential involved and the amount of space available.

By JOHN J. FRUIN, Ph.D.

PEDESTRIAN DESIGN FOR PASSENGER TERMINALS

The design of pedestrian facilities for passenger terminals is dependent on the category of terminal and its pedestrian traffic patterns. Commuter passenger terminals, with extreme but short peak traffic patterns and repetitive users, can be designed for lower standards of service than long-distance terminals, where the users are generally unfamiliar with the facility and peak traffic levels may be sustained over several hours. Detailed photographic studies of the use of pedestrian facilities indicate that maximum capacity coincides with the most crowded pedestrian concentrations, representing a poor design environment. Many of the elements of aesthetic design are lost in this type of crowded environment, as the pedestrian becomes preoccupied with the difficulties caused by the close interaction and conflicts with other persons. The challenge to the terminal designer is to balance the space requirements for a comfortable and aesthetically pleasing human environment against the space restraints caused by building configuration and cost.

The most recent approach to the design of pedestrian spaces has been the use of the level-of-service concept. On the basis of this concept, a qualitative evaluation is made of human convenience at various traffic concentrations and this is translated into appropriate design parameters. For example, it has been found through detailed photographic analysis that the maximum capacity of a corridor is ob-

tained when average area occupancies are about 5 sq ft per person and human locomotion is limited to a restricted, shuffling gait. Pedestrians require an average of more than 35 sq ft per person in order to select their normal walking speed and to avoid conflicts with other pedestrians. Human locomotion on stairs and the convenience and comfort of pedestrian waiting areas is similarly related to average pedestrian area occupancy.

Corridor Design

Minimum corridor widths are based on the pedestrian traffic flow volume less appropriate allowances for disruptive traffic elements such as columns, newsstands, stairways, window shoppers, etc. Where the corridor is also used as a waiting area to accommodate standing pedestrians, the maximum potential accumulation and safe human occupancy of the corridor should be determined. (See "Queuing Areas," below.) The maximum practical flow through a corridor is approximately 25 persons per foot width of corridor per minute (PFM). The flow volume that allows for the selection of normal walking speed and avoidance of traffic conflicts is equivalent to 7 PFM (or less). This standard would be used in passenger terminals that do not have severe peaking patterns or space restrictions. Where severe repetitive peaks and space restraints occur, such as in a commuter terminal, the more stringent standard of 10 to 15 PFM may be used. This standard allows the attainment of near-normal walking speed but does result in more frequent traffic conflicts with other pedestrians.

Entrances

The criteria utilized for corridor design can be roughly applied to the design of doors. The maximum capacity of a free-swinging door is approximately 60 persons per minute, but this capacity is obtained with frequent traffic disruptions and queuing at the entrance section. A standard of 40 persons per minute would be representative of a busy situation with occasional traffic disruptions. Where free-flowing traffic is desired, a standard of 20 persons per minute should be adopted.

Stairs

Human locomotion on stairs is much more stylized and restricted than walking because of the restraints imposed by the dimensional configuration of the stairs, physical exertion, and concerns for safety. As with corridors, capacity flow is obtained when there is a dense crowding of pedestrians combined with restricted, uncomfortable locomotion. The maximum practical flow on a stair is approximately 17 persons per foot width of stairway per minute (PFM) in the upward or design direction. An average of about 20 square feet per person or more is required before stair locomotion becomes normal and traffic conflicts with other pedestrians can be avoided. This is equivalent to a flow volume of about 5 PFM. This standard would be used in terminals that do not have severe peaking patterns or space restrictions. In commuter terminals, the more stringent standard of 7 to 10 PFM would be acceptable. Riser height has a significant impact on stair locomotion. Lower riser heights, 7 in. or less, increase pedestrian speed and thus improve traffic efficiency. The lower riser height is also desirable to assist the handicapped pedestrian.

Queuing Areas

A number of different pedestrian queuing situations occur in terminals which affect their functional design. Linear queues will occur where passengers line up to purchase tickets or board buses. Care must be taken that these lines do not disrupt other terminal functions. The length of a linear queue may be estimated on the basis of an average per person spacing of 20 in. The presence of baggage has little effect on this spacing because baggage is placed on the floor either between the legs or at the sides. Bulk queues may occur within a passenger terminal where passengers are waiting for bus arrivals or other services. Where no circulation through the queuing space is required, area occupancies as low as 5 sq ft per person may be tolerated for short periods. This allows standing pedestrians to avoid physical contact with each other. Where movement through the queuing space is required, such as in a passenger waiting concourse, an average area of 10 or more sq ft per person is required. Human area occupancies below 3 sq ft per person result in crowded, immobile, and potentially unsafe queues, particularly where pedestrians may be jostled off platforms.

Escalators and Moving Walks

The high costs of escalators and moving walks present difficult design quality decisions. The units are generally designed close to their practical operating capacities even though this practice causes pedestrian delays and queuing. Escalator and moving walk manufacturers will rate the theoretical capacity of their units on assumption of uniform step or space occupancies, but detailed photographic studies of pedestrian use of these units show that, even under the most crowded conditions, pedestrians will leave vacant step positions or gaps, thus reducing effective capacity. This is caused by the pedestrian's own personal space preferences and momentary hesitation when boarding these units, particularly when they operate at higher speeds. This has led to the use of a nominal or practical design capacity of 75 percent of the theoretical as shown in Table 1.

TABLE 1 Nominal Capacity—Escalators and Moving Walks

Type of unit	Capacity, persons per minute	
	Speed—90 fpm	Speed—120 fpm
32-in. escalator	63	84
48-in. escalator	100	133
24-in. walk		60
30-in. walk		120

Stationary stairs should be located in close proximity to escalators and inclined moving walks to allow for their alternative use in cases of mechanical failure. With a rise below 20 ft, pedestrians will also make alternative use of these stairs if escalator queues become too long. With high-rise applications above 20 ft, virtually all pedestrians will use the escalator, causing long queues and delays in the heavier traffic applications. Space for pedestrian traffic circulation and queuing should be allocated at all landing areas.

By JULIUS PANERO,
Architect and Planning Consultant

BUS GEOMETRICS

Bus Data Bus geometrics, or the physical dimensions and maneuverability of the bus, determine the width of roadways, shapes of platforms, column spacing, ceiling heights, and other aspects of bus-level design. The apparently insignificant detail of the right-side loading of buses often restricts terminal design possibilities.

Swept Path When a bus turns normally, it always turns about a point which is somewhere on the center line of the rear axle. This is true whether motion is forward or backward.

The turns required to accomplish the movement and positioning of buses are variable and differ considerably with the equipment encountered. The turning template provides a convenient graphic method to determine minimum clearances required. (See Fig. 3.)

ROADWAY RAMP

Bus Roadway Widths Ten-foot-wide single lanes will suffice for 8-ft-wide equipment. *Eleven-foot lanes are preferable* where ample terminal space is available and especially to accommodate equipment 8 ft wide, the use of which steadily is increasing.

Double-lane runways, enabling standing buses to be overtaken by other buses, provide a great advantage over one-lane runways because of the increased flexibility of operations that is made possible.

For the purpose of merely overtaking another

(a) SAWTOOTH LOADING

(b) PARALLEL LOADING

Fig. 4 Bus loading plans.

PLATFORM TYPES

Parallel Loading

- Requires *excessive* amount of space.
- Buses must usually wait until first bus exits.
- Large terminal requires pedestrian under/overpass facilities to protect passengers while crossing lanes.

Right-Angle Loading

- Disadvantages include:
 - 1 Outswinging bus door which forms a barrier around which passenger must pass.
 - 2 Bus maneuvering difficult.

Straight Sawtooth Loading

- Efficient—employed where lot is comparatively narrow and deep.
- Passenger has direct approach to loading door.
- Baggage truck can operate between buses for side loading.

Radial Sawtooth Loading

- Most efficient—buses swing into position along natural driving arc.
 - Space required at front is minimum—wide space at rear making maneuvering easy.
- (See Fig. 4.)

Fig. 5 Bus roadway widths.

bus or row of buses having no appreciable tail-out, double-lane runway widths should be at least 20 ft and preferably 22 ft, especially if extra-wide equipment is to be accommodated — immediately or in the future. However, for a flexible operation under which departing buses may pull out from the platform around a standing bus, the runway width and the amount of lineal space at the platform for the pull-out maneuver are directly related. This relationship is indicated by Fig. 5, from which it is seen, for example, that a 40-ft bus having a 16-ft clearance ahead actually uses 22 ft of runway width for the pull-out. This would indicate, for practical purposes, a runway width of at least 24

ft. Also, a total minimum berth length of 40 ft plus 16 ft, or 56 ft, would be required. Obviously, the shorter the berth length allowed, the wider the runway must be, and vice versa.

Ramping Where roadway ramping down or up, at entrances or exits to runways is necessary, care should be taken to avoid sharp grade changes which will result in discomfort to passengers or rough treatment of equipment, particularly when heavily loaded. Here again, where this factor is involved, tests should be made with buses and allowance made for possible future vehicles having a longer wheelbase and overhang. Because of the longer

CURVES SHOWING REQUIRED BERTH LENGTHS
AS COMPARED TO BUS TAIL-OUT
28' AND 40' G.M.C. BUSES

wheelbase of buses, critical attention should be paid to the vertical clearance where a sag curve exists, since required bus clearance will be greater. Where buses are to enter terminal buildings, doorways and other structures should allow sufficient side clearance to permit free movement of vehicles and to avoid damage and delay. Door headroom should be at least 12 ft for typical equipment, allowance being made for any use of the terminals by deck-and-a-half or double-deck buses. Actual dimensions of equipment to use the terminal should be checked before fixing critical dimensions. Minimum side clearance to all structures along the roadway should be at least 12 in.

A truck terminal is a highly specialized facility, designed for a specific function and operating plan in terms of the service standards it must meet, the area it serves, and the volumes to be handled. The objective of this article is to explain the planning required to assure that the facility will be adequate for:

1. *Dock design and yard layout.* Provide sufficient space for trucks to maneuver in and out quickly and for parking equipment. Protect freight and personnel from the weather. Design docks to provide ready access for moving material into trucks.

2. *Number of dock spots.* Provide the appropriate number of doors to enable trucks to load and unload without undue delay.

3. *Accumulation space.* Space is required immediately behind shipping and receiving spots for accumulating shipments so that vehicles can be processed quickly.

The complete design of the truck terminal, of course, depends upon first establishing the operating plan and mission. Evaluation and considerations of alternate handling systems and building designs are beyond the scope of this article.

Possible future changes must be thoroughly analyzed in establishing the design year requirements. Facilities are designed for the future, and they must be able to handle peak loads. Although the data gathering and analytical techniques required to accurately establish a design basis appear complex, they are necessary. Only with this information can the designer assure that the facility will operate as planned.

DESIGN YEAR REQUIREMENTS

The planning starts with a 5-year forecast. The planners have established the specific mission of the facility and have thoroughly estimated the needs of the future including:

1. Inbound and outbound destinations to be served
2. The nature of the workload to be handled
3. The terminal schedules required

The objective of the planning analysis is to establish a few numbers such as pounds per hour which describe what the terminal will have to do during the peak period of the design year day. The designer must know what the workload availability will be in terms of truck arrivals, dispatches, loading, and unloading times for peak operations.

1. *Determine design year peak.* Historical data are of interest only as they relate to the future. Usually, current information must be collected to describe the details of the present terminal workload, so that the data may be adjusted for the future. Determine how this current test period relates to the normal seasonal peaks and valleys encountered during the year. If the terminal is a new facility replacing an existing one, then data can usually be col-

lected for one point. If the terminal is replacing two or more existing terminals or has an entirely new mission, then information may be collected for several points. The designer, of course, would like to have complete information available to make his forecast, but he must be practical and use whatever information is at hand. The type of information which can be used for evaluating seasonal peaks and valleys is:

- a. Number of shipments
- b. Pounds handled
- c. Revenue dollars
- d. Number of loads

2. *Tabulate and analyze peak period.* Establish a logical basis for a peak period. Planning the facility to handle the absolute peak day 5 years in the future is not logical. This would mean unnecessary building cost. Select a peak period somewhat lower than the average, depending upon evaluation of daily or weekly variation. For a small facility, a 40-door terminal or less, a good rule of thumb is to take an average of the 10 highest consecutive weeks during the year and use this as a base to compare other periods of the year for which you are collecting detailed information. A larger facility deserves detailed analysis. Tabulate the daily or weekly data on a bar chart. Examine it, and establish some logical cutoff for the peak period. Usually a design base which will accommodate the volume of 85 to 90 percent of the working days of the year will be suitable.

3. *Establish the design year planning base.* The new terminal should be planned for 5 years hence. Site and yard space requirements should be planned for 10 to 20 years in the future to allow for expansion of the platform facilities and other facilities beyond the design year. Design year peak should include the following:

- a. The current planning base
- b. Forecasted growth for inbound-outbound transfer and interline freight
- c. Acquisition of operating rights within present system including new distribution points and peddle routes
- d. Mergers with other carriers and possible consolidation of terminals in the same city
- e. Change in the freight pattern

The design year daily volume should be in pounds. Be careful in projecting growth based on past revenue increases, because these usually reflect rate increases, not actual growth of traffic. The final figure established should represent the planned peak design year day in terms of total pounds handled. Detailed information on current workload can therefore later be adjusted to reflect a future planning base.

4. *Tabulate data on workload availability.* Set up the test period and accumulate 4 weeks of data by maintaining daily activity logs and records. The objective of this analysis is to provide complete information on all elements of the workload, to determine the time of its availability and what must be done with it. Daily activity logs should be maintained for:

- a. Inbound arrivals by origin point
- b. Delivery loaded by route and interline carrier

- c. Inbound break-bulk by origin and destination points

- d. Interline and cartage received by carrier

- e. Pickup unloaded by route

- f. Outbound loaded by destination

The availability logs should show the workload arrivals in terms of units (or trucks), shipments, and pounds, and when it arrived. At the end of each day, summarize the information on the logs to show the workload availability by hour. At the end of the 4-week test period, summarize the vehicle and freight activity for the entire period in hourly increments. Review the daily results for a consistent pattern of vehicle and freight arrivals and for variations from the pattern.

5. *Evaluate future changes.* Before establishing the design year workload characteristics and specific terminal mission, determine those workload availability changes which might occur in the interim, either through management direction or from other sources. Key factors to consider are:

- a. Different closeout times at origin terminals

- b. Changes in routing between origin and destination terminals which may alter travel time

- c. Changes in cutoff times for interline freight

- d. Feasibility of replacing single trailer with double trailer operations, to reduce elapsed loading or eliminate combination loads

- e. Possibility that double trailer combinations may mean earlier arrival at new terminal

- f. Break-bulk traffic patterns may change by review of system operation

For new areas to be serviced by acquisition of additional rights or by merger with other carriers, estimate the workload availability based on the location of possible new terminals and estimated freight volumes to be handled. Evaluate all of these factors, and establish the design year workload availability for the new terminal.

6. *Establish service objectives.* The planner now has available a good description of the new terminal workload in terms of its content and availability. The next step is to establish two key factors:

- a. Required cutoff times for outbound loading

- b. Required time that delivery vehicles should be available on the street

The planner, therefore, will know when the workload is available and how much time the dock crew will have for processing the workload.

7. *Establish distribution of traffic by outbound destinations.* The objective is to estimate the amount of traffic to be loaded over the platform to each outbound destination to be served. Tabulate the daily average test period weight in pounds to each destination. The procedure is as follows:

- a. Tabulate daily average weight in pounds to each destination.

- b. Apply the forecasted growth factor to each destination for design year daily average weight. If forecasts are not available by destination point, use the same growth factor for all points.

c. List all new destination points acquired through operating rights or mergers with other carriers.

d. Determine design year daily average out-bound weight for each new point.

A similar analysis should be prepared for in-bound traffic. List all present routes, including commercial consignees and interline carriers. Evaluate these routes and determine whether future plans will call for rerouting and handling additional volume by more routes, improved delivery load averages, or more trucks on the same routes. Tabulate the expected volume of freight for each route.

At this point, the planner should have a complete description of the future workload, when it will be available, where and how it must be loaded, and what the loading and unloading—overall handling capacity required—will be for the design year day.

NUMBER OF DOORS

The number of loading and unloading doors required is based on the peak period during the design day. The peak doorway requirement may be for the inbound operation or a peak where the inbound and outbound overlap. The planner has already established the volumes to be handled, the destinations to be sorted, and the availability of freight to be unloaded. The number of doors for a given workload will therefore depend upon the number of destinations to be loaded inbound and outbound as well as the rates at which freight can be loaded and unloaded through a door. Typical truck terminal unloading and loading rates are shown in Table 1. These may be used if the planner has not already established loading and unloading rates for his own operation. The rates shown are based on the number of pounds per hour which normally can be loaded and unloaded through a doorway based on a one-man operation. The rates also include time for spotting equipment.

1. *Calculate outbound doors required.* For outbound, obviously the minimal requirement is one door per destination. Additional doors will be needed for destinations which have a greater volume of freight than can be loaded through a door in the required time period. Let us say that a carrier has four destinations and can load freight through a doorway at a rate of 6,000 lb per hour. The design year requirement for the peak period during the design day has been established. The calculation is as follows.

Example: There are four destinations, and the average loading rate is 6,000 lb per hour.

Destination	Pounds per hour to be loaded	Number of doors calculated	Number of doors allowed
A	10,000	1.7	2
B	4,000	0.7	1
C	25,000	4.2	4
D	2,000	0.3	1
Total	41,000	6.9	8

As a rule of thumb, when determining the number of doors for each destination, round all decimal values of 0.3 to the next higher whole number, and drop all decimal values less than 0.3. When calculating the number of outbound doors, be sure that all destination points are well defined. For example, Chicago might be a destination. There may be additional sub-destinations required such as Chicago proper, Chicago interline, and Chicago route truck. Each of these would have to be treated as

TABLE 1 Loading and Unloading Rates*

Shipments		
Type	Average pounds	Pounds per hour†
Very small shipments‡	150	2,000- 4,000
Small shipments	300	4,000- 5,500
Average shipments	500	5,500- 6,500
Large shipments	3,000	6,500- 8,000
Unit loads§		22,000-30,000
Containers¶		17,000-21,000
Conveyor loading		9,000-11,000

*Rates based on steady flow of freight to or from doorway. Pounds per hour will decrease if freight flow is interrupted to pick or detail inspect shipments and to travel long distances between storage and shipping or receiving area.

†Rates are based on one-man operation. With two-man operation rates will increase 50 percent to 80 percent.

‡Includes large percentage of minimum shipments and one shipment delivery or pickup. Minimum service time is 6 minutes per vehicle.

§Includes pallet loads, skid loads, clamp loads, and slip sheet loads.

¶Includes cages, metal, wood, and plastic containers.

separate destinations if the freight is sorted for them and loaded separately.

2. *Calculate number of inbound doors.* The number of doors for local delivery will depend upon the number of routes and the method used for servicing the route. Before calculating the number of doors, the operating plan must be established. The planner must know:

a. The number of dropped trailers or trucks for interline or large customers

b. Whether the plan calls for flooring freight and loading all trucks in sequence, or whether the inbound operation will be all or partially a cross-dock or direct-loading operation

c. Whether all delivery vehicles will be dispatched at once or whether there will be a second wave of local delivery

Use the planning data developed to determine the volume of freight for each route. Develop the operating plan, and provide enough truck spots for each route to be loaded at any one interval of time.

3. *Calculate number of doors required for unloading.* The calculation of the number of doors required for stripping or unloading inbound trailers or pickup and delivery vehicles is relatively simple. From the design day peak workload analysis, the planner knows the volume of traffic, its availability and how much must be stripped in a given number of hours. The only additional information needed is at what hourly rate he can expect a dockman to unload freight through a doorway.

Example

A carrier's daily peak period is during the inbound operation. The plan calls for dock crews to start in force at 2 A.M. and complete unloading inbound trailers by 7 A.M. Workload availability analysis shows that 300,000 lb of inbound is available for stripping during this period. The elapsed time for the operation is 5 hours. Stripping is planned at a continuous level rate; then the crew has 5 hours to complete the unloading. The plan will require stripping inbound vehicles at a rate of 60,000 lb per hour. Delivery can be loaded at an average rate of 4,000 lb per hour through a door; then the number of doors required for stripping is:

$$\frac{60,000}{4,000} = 15 \text{ doors required}$$

Similar calculations can be made for stripping pickup vehicles. Important factors to know are when the pickup is available, and at what continuous rate stripping should be planned in order that the unloading be completed in time to close out the outbound equipment on schedule.

SHIPMENT ACCUMULATION SPACE

Accumulation space is needed to stage shipments so that they are ready for the pickup vehicle and for placing goods received prior to disposition. Shipments should be staged in an area convenient to the truck dock.

Accumulation space may contain storage aids such as racks, bins, or shelves. Shipments may be accumulated on pallets, skids, carts, trucks, or in containers. The space might also be occupied with conveyor banks to accumulate orders or merely contain cartons stacked on the floor.

In an operation in which all freight is moved directly into vehicles spotted at the dock, accumulation space is not needed. In this case, the vehicle serves as the accumulation area, and having been filled with freight, is replaced with an empty.

1. *Determine peak accumulation.* The accumulation space should be calculated for the design year. Adequate space must be available for the total shipment accumulation volume for the peak hour of the day. The warehouse is picking orders at a certain rate and loading trucks at certain times. The accumulation space requirement, therefore, must provide storage for the cumulative total of orders picked during the day minus the cumulative total of orders loaded out. By tabulating both of these cumulative volumes by hour, the planner can determine when the peak will occur as well as what the peak volume needing to be stored will be. The peak accumulation for most facilities will generally occur sometime in the early afternoon, just prior to the peak arrival period for carriers.

2. *Calculate space required.* Convert the maximum accumulated volume for the peak into cubic feet. Convenient conversion factors can be established for converting pounds or cases into cubic feet. Finished goods, however, are not accumulated in one solid mass. Additional space must be provided for access and for separation of shipments by carrier. For most conditions, the allowance for additional space is usually about 2½ to 3 times as great as the actual cube of the product. Therefore, multiply the finished goods cubic feet by the storage space utilization factor of 2½ to 3 to obtain total storage cubic feet required.

3. *Prepare block layout.* The next step in planning the shipping accumulation space is determining the number of square feet. The procedure is as follows:

a. Determine the overall stacking height for the shipment to be stored.

b. Divide the total storage cubic feet by the stacking height.

TRUCK TERMINALS

The result will be the storage area in square feet.

Additional space must be provided for access aisles. Depending on the storage aids used, area requirements for aisles will range from 50 percent to 150 percent of the storage area, according to the size of the storage bank, type of equipment used, and whether aisles are used for more than one purpose. In most cases, the allowance for aisles is equivalent to the storage space available. Prepare a typical layout for one bay. Measure storage space and, based on aisle space needed, multiply the storage area in square feet by a factor of 1.5 to 2.5. The total square feet should provide adequate space for shipment accumulation. Draw a layout of the configuration of the area, giving the required number of square feet, and arrange the storage blocks on the layout as they actually will be. If adjustments must be made in space allowances, make them at this time.

DOCK DESIGN AND SPECIFICATIONS

The third major element in planning the shipping facility is to see that docks are the proper height for loading and unloading vehicles, that people and freight are protected from weather, and that adequate space is allowed for access and parking. Once again, plan for the design year and allow for expansion.

1. *Determine vehicle parking requirements.* Estimate the following for the design year: Company or contract carrier vehicles

a. If company trucks or contract carrier vehicles are used for distribution, determine the maximum total number and type of vehicles on site. This maximum number will generally occur on a weekend or over a holiday.

b. Multiply the number of each type vehicle—such as 40-ft trailer, 18-ft straight truck, tractor with 40-ft trailer—by the square foot allowance for each different length of vehicle. Parking space for a vehicle should be 12 ft wide, and the length of the space should be the overall length of the vehicle plus 20 percent.

Parking space per vehicle, sq ft
= (overall length, ft \times 1.2) \times 12 ft

c. Add total space requirement for all vehicles.

d. Subtract space for number of vehicles to be spotted at the dock.

e. Calculate truck apron area, employee parking area, and service road area. Total area for combined facilities.

Common carrier vehicles

a. Estimate the maximum number and size of vehicles which could be waiting for a door position, and provide space for these vehicles.

b. Keep apron and dock approach area clear to permit rapid removal and spotting of vehicles at the dock.

2. *Provide adequate maneuvering space.* The length of a vehicle's parking space or dock approach is the greatest length for the tractor-trailer combination (stall length) and the apron length necessary to maneuver the vehicle in and out of the parking spot. The apron is measured from the outermost part of the longest vehicle to be accommodated or from the outermost part of any obstruction, such as a post or part of a building structure in front of the dock. As a general rule, the dock approach should be at least twice the length of the longest tractor-trailer combination.

The width for each new parking spot or stall should be 12 ft to accommodate the longer and

wider tractor-trailer combinations. This width can be used for outside parking or parking in an enclosed dock area. Use Table 2 as a guide.

TABLE 2 Minimal Parking Space or Dock Approach Length and Width (Width—12 ft)

Overall length of tractor-trailer, feet	Apron length, feet	Dock approach length, feet
40	43	83
45	49	94
50	57	107
55	62	117
60	69	129

3. *Plan for good traffic flow.* When preparing the plot plan, include:

a. *Vehicle movement on site.* Vehicles should circulate in a counterclockwise direction. Making left-hand turns with large vehicles enables the driver to see more easily the tail end of the vehicle.

b. *Service roads.* For two-direction traffic, roads should be 23 ft wide. This will allow for a 3-ft clearance between passing 8½-ft-wide vehicles with a 1½-ft side clearance. For one-way roads, the minimum straightaway width should be 12 ft.

c. *Roadway approaches and intersections.* Gates and approaches to roadways should be at least 30 ft wide for two-direction traffic and at least 20 ft wide for one-way traffic. For a right-angle roadway intersection, a minimum radius of 50 ft will be satisfactory for most vehicles. However, if the road is wider than 20 ft, the minimum radius may be decreased to 35 ft.

d. *Pedestrian lanes.* These should be located adjacent to a service road, but separated from the roadway by a physical barrier. The width of the lane can range from 4 to 6 ft, depending on the volume of pedestrian traffic.

4. *Provide proper dock height.* Truck-trailers and pickup and delivery vehicles are not built to any specific bed height; therefore, docks for vehicles at plants and distribution centers cannot be constructed to one specific height. For most trailers designed to handle dry merchandise, the vehicle bed height will vary between 48 and 52 in. For some high-cube trailers with smaller wheels, the bed height will be less than 48 in. Truck chassis with a "reefer" body will increase the bed height up to 6 in. Pickup and delivery vehicle bed heights will vary between 44 and 50 in. Vehicles with capacity loads can compress springs and change the bed height. A single-axle trailer bed height can change as much as 6 to 8 in.

To provide the best dock height for a facility, a survey should be made of the type of equipment used to determine the bed height of vehicles servicing the plant or distribution center. Different heights may be provided if all straight trucks arrive at one dock location and all trailers arrive at another. In general, selecting a dock height lower—rather than higher—will enable the driver to open or close vehicle doors while the truck is at the dock.

5. *Avoid pits and ramps.* If at all possible, grade the approach and apron area for the proper dock height and keep equipment near level. If loading pits and ramps cannot be avoided, use the following guidelines:

a. If a ramp is needed, grade the approach to the dock so that the truck or trailer is nearly level. Equipment parked at a steep angle is unsafe to load and unload. If the front end of the truck or trailer is elevated too much, the truck

roof may strike the building when backing in.

b. Although most loaded trucks are designed to pull a 15 percent grade, the start-up grade for pulling away from a dock is much lower. In addition, dock facilities even if covered cannot be kept dry in wet weather. A 3 percent grade is the maximum allowable for pulling away from a dock.

6. *Specify door height and width.* Almost all shipper-consignee facilities should have truck dock doors to provide security and dock area protection from wind, rain or snow when vehicles are not at the dock. For most installations, a 9-ft door width is recommended for vehicles not perfectly spotted. Trailer widths may increase in the future to 102 inches. Door widths greater than 9 ft will cause excessive loss of heat or refrigeration; doors less than 9 ft wide will require extra maneuvering of vehicles for spotting at the dock.

To determine door heights, subtract the dock height from 14 ft. In most cases the door height will range from 9 ft 8 in. to 10 ft. This height will accommodate up to 13-ft 6-in.-high trailers. If only straight trucks deliver and pick up freight at the dock, the height of the door will range between 8 ft and 9 ft 4 in.

7. *Install permanent, self-leveling dockboards.* Installation of dock levelers enables faster turnaround of trucks and contributes to increased dock productivity. Permanently installed boards are safer to use than portable boards. The one exception to the use of dockboards would be for facilities exclusively utilizing conveyors to transport freight out of or into vehicles.

The dockboard specification will depend on the following factors:

a. Greatest height difference between the dock and bed of trucks or trailers serviced

b. Type of materials handling equipment used

c. Type of loads handled into and out of vehicles

d. Type of vehicle road equipment picking up or delivering freight

After determining the maximum height difference from dock level, the length of the dockboard can be calculated by using the allowable percentage grade for the type of handling equipment used. Allowable grades are shown in Table 3.

TABLE 3 Percent of Grade for Material Handling Equipment

Type of equipment	Allowable percent of grade*
Powered handtrucks	3
Powered platform trucks	7
Low-lift pallet or skid trucks	10
Electric fork trucks	10
Gas fork trucks	15

* Contact manufacturer and check manufacturer's specifications before operating beyond allowable percent of grade.

Most standard truck dockboard lengths range from 6 to 10 ft. For most applications, dockboards should be 6 ft wide. Use 7-ft wide dockboard for loading or unloading unit loads with fork truck.

8. *Provide area for access to trucks.* A minimum area measured inside the plant from the edge of the dock should be kept clear and unobstructed for the movement of freight and materials handling equipment. The depth of the area must allow for maneuverability of materials handling equipment in and out of vehicles and for two-way cross traffic behind the dock. If dockboards are used, provide a minimum

depth of 12 ft behind the inside edge of the board. If dockboards are not used, allow 15 ft from the dock edge. If conveyors are used to load and unload all freight, the requirement for a clear distance behind the dock edge will not apply.

9. *Provide for weather protection.* An alternative to a fully enclosed dock is the installation of dock shelters and canopies completely enclosing the space between the building and the rear of the vehicle. Dock shelters provide a closure between the truck and dock doors. Canopies provide a roof over the dock and should be extended over the dock's entire distance. In order to reduce the effects of wind, rain and snow, the installation of canopies should also include side panel walls extending from the building at each end of the dock area.

Most shelters are designed to accommodate vehicles ranging from 10 ft to 13 ft 6 in. high. Dock shelters should be considered for plants and distribution centers which have the following characteristics:

- a. Plant site is located in cold, windy or wet climate.
- b. A large concentration of people work in the area and the adjacent dock area.
- c. Female employees, performing stationary tasks, are located near the dock area.

d. Long loading and unloading time intervals occur at the dock.

e. There is a limited range of vehicle sizes picking up and delivering freight.

Canopies should extend a minimum of 8 ft out from the building to provide adequate protection over the rear end of parked vehicles at the dock. For level driveways, the outside edge of the canopy should be no less than 15 ft high to accommodate 13-ft 6-in. trailers. If the height of all vehicles using the dock is less than 13 ft 6 in., locate the canopy 1½ ft higher than the highest vehicle.

10. *Evaluate fully enclosed dock.* The initial cost of constructing a completely enclosed dock facility, compared with an outside dock facility, may be justified if:

- a. Maximum security is needed.
- b. Plant site is located in cold, windy or wet climate.
- c. Vehicles are dropped for overnight loading.
- d. High value merchandise is handled.
- e. Merchandise handled is sensitive to temperature and water.
- f. A large concentration of people work in the area and the adjacent dock area.

If a dock is completely enclosed in a building, the width of each dock position should be a

minimum of 12 ft wide. The overall clear height in the vehicle docking area should be a minimum of 1½ ft higher than the highest vehicle or legal height. For most installations, this will be a 15-ft overall clear height.

The back-in type enclosure is the most common type of completely enclosed dock facility. For this enclosure, each vehicle dock position has its own doorway for direct access to the outside as shown in Fig. 1. The distance from the leading edge of the dock to the inside of the doorway where the vehicle backs in should exceed the maximum length of the vehicles using the facility or the maximum legal length of the vehicle combination by at least 5 ft. For most installations receiving tractor-trailers, an overall length of 65 ft will meet this requirement.

DOCKING FACILITIES

The primary consideration in planning modern loading and unloading facilities for motor transport equipment is to provide adequate space for efficient maneuvering into and out of loading position at properly constructed docks. No one plan will fit all requirements, but careful study of present needs and future possibilities will determine the type and size of facilities essential to efficient operation.

There is, of course, no set of standard dimensions covering the space required for maneuvering the many possible combinations of tractor-trucks and semitrailers into and out of loading position at docks or in stalls and driveways. However, the maneuvering space required is largely dependent on three factors: (1) overall length of the tractor-trailer unit; (2) the width of the position in which the vehicle must be placed; and (3) the turning radius of the tractor-truck which pulls the unit. Inasmuch as a tractor-trailer uses slightly more space to pull out than to back in, all reference to maneuvering apron space is based on the requirements for pulling out.

Length of Tractor-Trailer Unit

The length of tractor-trailer units to be accommodated will vary in accordance with state laws and differing types of operation. Analysis of the specific problem will determine the largest vehicle to be considered. For the purposes of this discussion tractor-trailer units of 35, 40 and 45 ft are considered to be the most prevalent overall lengths. If an appreciable volume of traffic is handled by "for hire" motor transport, it may be expected that the unit length to be accommodated will approximate the legal limit in the state concerned, usually between 45 and 50 ft. It is obvious that commercial haulers will use the maximum size tractor-trailer practical for efficient operation within state limitations. In general, it may be assumed that straight trucks can be accommodated in the space required for tractor-trailer units inasmuch as it has been impractical to build trucks even approaching the length and cubic capacity of modern trailers. In some states trains of more than one trailer are permitted. Such equipment is not being considered as it is assumed that each trailer in a train would be spotted separately.

Width of Position

The maximum allowable width of a truck or trailer is 8 ft and it may be assumed that virtually all units (other than those for light city delivery) are built to take full advantage of this dimension.

Fig. 1 Back-in type enclosure.

Transportation

TRUCK TERMINALS

- NOTES: (A) Should be at least 6 in. over legal height for level area, more for slope.
 (B) Dock height, 48 to 52 in. for road trailers, 44 in. for city trucks.
 (C) Concrete apron of the dimensions shown will accommodate trailers from 22 to 40 ft long.
 (D) Additional slab length recommended to support tractor wheels.
 (E) General rule for distance required: total length of tractor-trailer times 2.
 Trailer width—8 ft
 Trailer stall width—10 ft minimum, 12 ft recommended.

Fig. 2 Recommended dimensions and clearances for truck loading docks.

The consensus among transport and traffic men interviewed is that 12 ft is a very desirable width for stalls or truck positions. Slightly narrower position widths can be utilized when necessary but should be avoided in order to reduce the possibility of damage to equipment and loss of time for jockeying into position. Also, as position width increases, the apron space required for maneuvering will decrease.

Trailer Dimensions Average dimensions of large trailers are shown in Fig. 2, along with recommended dimensions and clearances for dock structures.

Turning Radii of Tractor-Trucks

The turning radii of tractor-trucks have a definite bearing on the apron space required for maneuvering equipment. However, because of the variation in this dimension among trucks of different types, capacities and makes, a high average turning radius has been used in arriving at recommendations regarding space requirements.

The requirements of heavy-duty units with extremely long turning radii call for special consideration. If such equipment is a factor in any operation, a special study should be

made to determine the space required. Units utilizing cab-over-engine truck-tractors have somewhat shorter turning radii for the same lengths and consequently require less apron space than units with conventional tractors. Many of these tractor-trucks are in use, but few shippers can count on their exclusive use.

Apron Space Required

The apron space required to maneuver tractor-trailer units into or out of loading position in

one maneuver has been worked out in practical tests with standard equipment handled by experienced drivers. Inasmuch as a high average turning radius has been arbitrarily used to provide a margin for differences in equipment, the variable factors were overall length and position width. The apron space required is measured out from the outermost part of any vehicle or other possible obstruction in the area of the maneuver (Fig. 4).

In the case of a single-position unobstructed dock (Fig. 4a), the distance would be measured straight out from the dock. However, if a canopy or roof, supported by posts (Fig. 4b) should be present to protect the loading area, the distance would be measured out from the posts. If it is necessary to spot a trailer alongside another vehicle (Fig. 4c), the distance would be measured from the outermost point of the vehicle obstructing the maneuver. When a stall or driveway is involved (Fig. 4d), the distance would be measured from the outermost obstruction, such as a curb, pole, or vehicle, etc.

It is highly recommended that at least the minimum apron space be allowed and that it be kept clear for the approach and maneuvering of transport units.

In locations where the proper space is not available for parking in one maneuver, trailers can be jockeyed into position. This, however, is a time-wasting, costly, and unsatisfactory process for both commercial and private transport operators.

Overhead Clearance

Standard trailers vary in height up to 12½ ft. Consequently, it is recommended that 14-ft clearance be provided at docks or in yards, driveways, doors, stalls and interior roadways. Special transportation conditions such as delivery of large machinery may require greater clearance.

When designing for ramps, dips, or crowns in the terminal area, special care must be taken to provide clearance at the points indicated in the diagram. Actual dimensions must be obtained. Cab clearances are more critical when the combination is jackknifed. Landing gear height (A) may be as low as 10 in.

Fig. 3 Critical points for clearance.

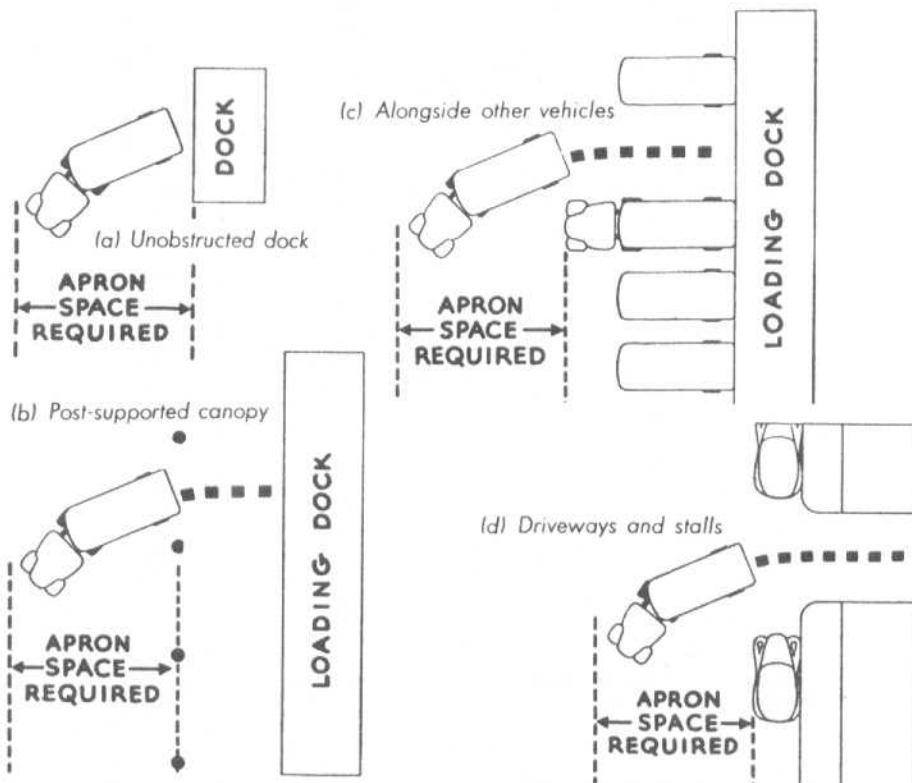

Fig. 4 Apron space required for various conditions.

Fig. 5 Turning clearance for driveway.

Drainage

Roofs or canopies over loading docks should be constructed so as to avoid drainage into the loading area. This precaution will reduce the hazards of mud and ice and the resulting loss of traction. It is particularly important to prevent ice formation on the pavement where tractor and trailer are coupled.

Traffic Congestion

So far as possible, loading areas and approaches should be free from general traffic

and obstructions. Railroad crossings, automobile traffic, parked vehicles, and material carelessly stored outside all contribute to delays in pick-up and delivery. If a right-angle turn must be negotiated in a narrow driveway, extra clear space should be provided on the inside of the turn to eliminate maneuvering.

For instance, in a driveway 12 to 14 ft wide, the triangular area, formed by the inside corner of the turn and the two points 24 ft on each side of the corner, should be left clear. This will allow proper clearance for the turning radius of the tractor-truck and the cut-in of trailer wheels.

Turning Clearance (see Fig. 5)

Site

Location: In selecting a site, consider the following factors:

1. Proximity to pickups, deliveries, and connecting carriers
2. Accessibility to main traffic arteries
3. Obstructions such as bridges, underpasses, and railroad crossings
4. Zoning
5. Urban and regional plans; future growth pattern of city
6. Transportation facilities for employees
7. Utilities

Grade: Site should be approximately level; maximum slope 3 percent; minimum slope for drainage, 1 percent. Storm drains recommended 60 to 75 ft on centers, 100 ft maximum.

Pavement: 6-in. concrete slab reinforced with 6 by 6 in. No. 8 gauge welded wire mesh; expansion joints 30 ft on centers.

Fence: 2-in. wire mesh No. 9 gauge, 7 ft high including several strands of barbed wire at the top. Protect the fence from damage by trucks by placing bumpers or 2-ft-high earth curbs 5 to 15 ft from the fence, depending upon the type of truck using the yard. In car parking areas place bumpers at least 3 ft from the fence.

Dock Building

Orientation: If possible, place the long dimension of the building parallel to the prevailing storm winds.

Column spacing: Depends upon stall width. Recommended stall width 12 ft, column spacing 24 ft.

Width of building varies from 45 to 70 ft, depending upon the type of operation: usual figure is 60 ft.

Height: Minimum clear interior height, 12 ft. **Roof overhang or canopy projection**—3 ft minimum, no maximum (the longer the better); usual figure, 12 ft.

End walls: May be extended a similar distance for better weather protection.

Doors: Overhead type, 8 to 10 ft wide by 8 to 9 ft 4 in. high; the larger sizes are more usual.

Floor: Reinforced concrete designed for a live load of 150 to 250 psf; nonslip finish (float or abrasive).

Bumpers: Wood usual; steel or rubber may be used.

Steps: Iron bar rungs set in concrete dock front are less expensive than stairs; provide one set of steps per four stalls.

Light: 15 footcandles recommended; skylights optional. Floodlights arranged to shine into truck or trailer bodies are required, also floodlights for the general yard area.

Heat: Required in northern areas; suspended unit heaters or radiant heat in floor slab may be used.

Ventilation: Mechanical ventilation required if fork-lift trucks are used.

Sprinklers: Recommended for entire dock area. (See Figs. 6 and 7.)

Offices

The office facilities may include any or all of the following:

- General office
- Message center
- Billing office
- Cashier
- Telephone room
- Foreman's office
- Office manager
- Terminal manager
- Operations manager
- Salesmen's room
- Record room
- Heater room
- Central checking
- Drivers' locker room
- Transportation department
- Dormitory
- Cafeteria
- Drivers' ready room

Other Facilities

- Maintenance shop
- Fueling area (near shop)
- Weighing area
- Truck and trailer parking area (two parking spaces per dock stall recommended)
- Employee and visitor parking area

DESIGN CONSIDERATIONS

Site Planning—Some Physical Design Guidelines

Planning specific building sites in industrial developments requires a number of considerations. These considerations include setback requirements, truck loading and maneuvering depths, vehicular parking needs, building coverage, and rail service requirements.

Building setbacks from the fronting street will vary between setting the building on the property line and therefore having a zero front yard, to a setback of 50 ft or more. If vehicular parking is placed in front of the buildings, and allowed on one side only, 40 to 45 ft should be provided for the driveway and parking stalls. If parking is allowed on both sides of the driveway, 60 to 65 ft should be provided. Side and rear building setbacks usually will be less than front setbacks. They typically range from no setback required to 15 ft. Truck and rail loading needs may control building setbacks along side and rear lot lines.

Truck loading and maneuvering depths from edge of dock to edge of maneuvering area are variable depending upon anticipated traffic. Successful warehousing operation can occur with as little as 85 ft of truck docking and maneuvering depths, whereas the recommended depth for trucking terminals for larger trucks (45-ft trailer length) is as much as 129 ft. (See Fig. 1.)

Vehicular parking needs will depend on building use. Warehousing generally will have fewer occupants which enables auto parking to be accommodated near the front end of the truck loading area. Higher densities will require devoting as much as one side of the building to vehicular parking. Seventy-five feet should be allowed for parking and landscaping if one aisle, and parking stalls on either side, are considered sufficient. The ratio of parking spaces required to building will relate to employee densities and to employee commuting habits. Keeping the area of pavement to the minimum required to accommodate parking needs will have significant effect on storm drainage design. The developer, users, and public agencies will be well advised to design parking standards with this objective in mind and to provide minimum parking with initial site development with provision for additional expansion as empirical studies indicate.¹

SOURCE: Industrial Development Handbook, ULI—The Urban Land Institute, Washington, D.C., 1975.

¹ *Special Traffic Generator Study—Industrial Generations*, Report no. 2 (Dover, Delaware: State of Delaware, Department of Highways and Transportation, 1973). This report prepared detailed analyses of 22 industrial users, the parking ratios ranged from 0.21 spaces per 1,000 square feet of floor area to 20 spaces per 1,000 square feet of floor area. The firm with the lower ratio manufactured chemical products; the firm with a higher ratio was a clothing manufacturer. Of the 22 industrial firms studied, 11 had ratios of less than one space per 1,000 square feet of floor area; six had ratios of less than two spaces per 1,000 square feet of floor area; and only five had over two spaces per 1,000 square feet of floor space and with the exception of the one with 20 spaces per 1,000 square feet of floor area, all of these were below a four-to-one ratio.

To provide maximum return on investment, building coverage which gives the highest percentage site coverage is generally desired by the developer. However, building coverage may be limited by zoning or by parking needs of the occupants. Building coverage above 50 percent often can be achieved for warehouses whereas offices and light manufacturing, with their sizable parking needs, may be in the 30 percent range of building coverage.

Rail service requires about 15 ft from the centerline of the spur track to the rear property line when the drill or lead track is centered on the property line. If, however, the rail drill track is in its own right of way, then inside building rail service is most economical of land and improvement costs if the building can be constructed to the property line. An allowance of 150 feet should be made for bringing the rail from the lead track to a point parallel with the building. This is important in planning the distance from the building to the side property line because rail spur geometrics will require an easement on the property next door if the building must be set near the side property line.

Building dimensions are variable; however, most structures fall within the square to two-to-one ratios of length to width.

Platting Techniques

A primary objective in preparing a preliminary plan for industrial development is to provide maximum flexibility. Because the needs of prospective users cannot be known in advance, the layout of streets and rail leads must be done to create a plan which provides lots of various depths. Lots 200 to 300 ft in depth are popular. Large lots

may range from 500 to 700 ft in depth. Establishing lots for such depths will permit later introduction of a short cul-de-sac street to break these deeper lots into two medium-depth parcels.

Cul-de-sac streets should end in a paved turnaround 100 ft in diameter. This diameter will accommodate larger trucks, including 45-ft trailers, and will allow a 180-degree turn without backing.

A further objective of lot layout should be to minimize the number of at-grade rail crossings of major roads within the development. In areas with high density uses, such vehicular traffic interruptions are particularly annoying; and automatic crossing protection is often required at the developer's expense.

Submittal of a preliminary plan to the community reviewing agency will establish a pattern for the orderly submittal of record plats. While practices vary, it is desirable to make a minimum initial commitment when filing a record plat of roads and parcels. This minimum commitment will retain flexibility and will provide control over the amount of funds paid in filing fees, when these fees are based on area recorded. (See Fig. 2.)

Rail Service

When rail service to industrial developments is contemplated, the developer should contact the railroad company's industrial development department as early as possible to determine which provisions are necessary for service. As ULI Industrial Council member O. G. Linde points out, such things as reciprocal switching limits, frequency of switching service, car supply, and general rate considerations, can be very important. He suggests, "A project might experience slow development simply because the development is located

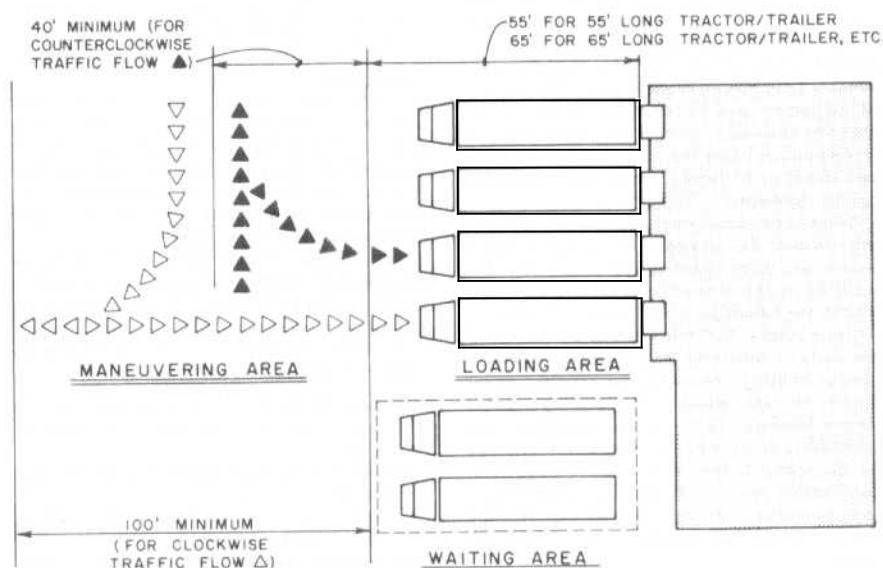

Fig. 1 Truck loading and maneuvering configuration.

Fig. 2 Utility and pavement relationship in an industrial park in St. Louis County, Missouri.

outside reciprocal switching limits, thereby making it unattractive for industries to locate at a local station on one railroad when a significant share of their rail traffic originates or is destined on other railroads."

Assuming the desirability of rail service has been determined and the mix of land to rail served versus nonrail has been determined by market studies, several engineering and design factors must be considered—including topography, soil conditions, drainage, existing improvements, right-of-way access, building setback requirements, operational requirements, elevation and alignment of existing tracks, desire for in-plant rail service, and most suitable point(s) of intersection with existing tracks. As ULI Industrial Council member Otto Pangrasc points out, "The location of rail access and the direction of that access from the main line must be discussed with the serving railroad since they may object to the point and direction of service that is most desirable for the developer."

While procedures vary, the cost of the lead track through the development is generally borne by the developer including the switch and spur track up to the property line of the individual tenant; the tenant generally pays for the remaining spur length. The railroad may participate in the costs of providing lead tracks to serve the several industrial sites within an industrial development through refunds to the developer based on car loadings. Switching tracks, sidings, and yards for storage may be necessary if required by the railroad. This additional trackage is of considerable value to the railroad since it facilitates operations. The developer should negotiate the cost of such additional trackage with the railroad.

Historically, the community has not been involved in the provision of rail service. It has been

the function of the developer to work with the railroads and share the costs based on mutual benefits. This function is in contrast to other onsite and offsite improvement such as streets and utilities. Frequently, communities have lent public powers such as improvement district financing in order to provide these facilities to further development of an employment and industrial tax base for the community [sic].

All rail service must conform to the requirements of the railroad company which will be operating over the facility. Also, rail service is subject to public service commission requirements. Many states have rules and regulations prescribed by lawful authority for clearances to or under adjacent buildings, structures, or physical obstruction of any kind.

Approval of railroad plans and construction is at the discretion of the railroad company. Close contact with railroad officials is desirable throughout all phases of planning, design, and construction. Agreements must be made between the railroad company and owner for operation and maintenance of private tracks.

The railroad company may furnish guidelines and standards for design. Every effort should be made to obtain the required information prior to any detailed layout.

For design purposes, the following information should be obtained from the railroad:

- maximum horizontal curvature and minimum tangent distances allowed for the type of layout,
- maximum grades allowed for transfer and storage,
- vertical curve requirements and maximum rate of change of grade,
- standard vertical and horizontal clearances—for lateral clearances, between centerlines of track and to fixed objects,

- turnout numbers to be used from the existing track and within the proposed layout,
- lead distances for the turnouts to be used,
- weight of rail for existing track and for proposed track,
- typical sections for roadbed width, slopes, ballast, ties, and rail configurations, and
- technical specifications.

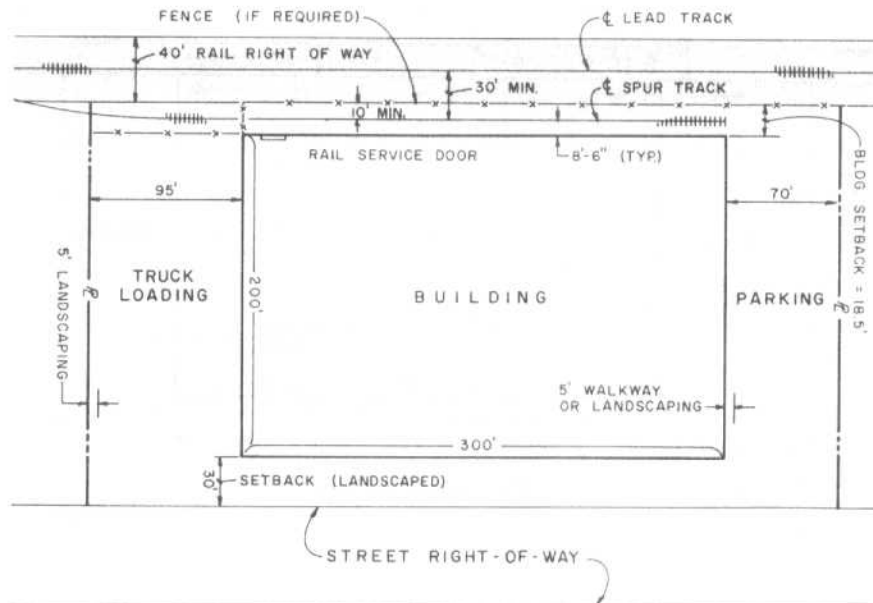

Track design standards, such as standard rail section, turnouts, guard rails, frogs, plank crossings, signals, and others, are available from the railroad company.

Other design considerations include drainage, earthwork, slope stability analysis, crossings, rights-of-way, and special conditions required for the project. (See Figs. 3 to 8.)

Whether done by the railroad or by the developer, the construction of all tracks and appurtenances should conform to the best construction practices as prescribed by the *Manual* of the American Railway Engineering Association (AREA).

As a rule-of-thumb, when a development is rail-served: (1) the rail lead track and nearby street elevations will generally approximate one another; (2) the minimum radius of curvature of the track will be between 350 and 400 ft; (3) maximum permissible gradients along spur tracks will be about 1½ to 2 percent; and (4) the dock height should be set from 3.5 to 4.0 ft above top of rail of the spur track.

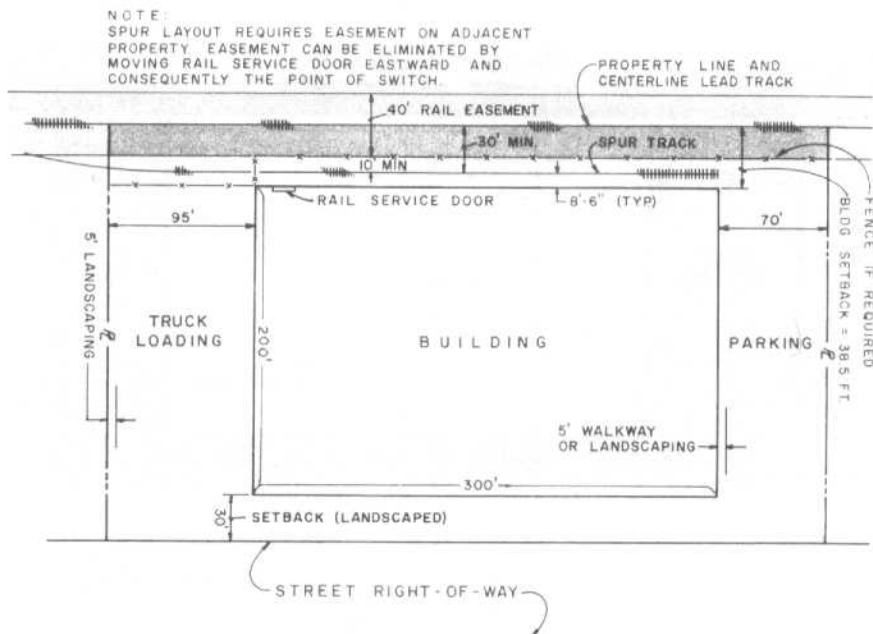

In deciding whether to provide rail service, and what portion of a development should be rail served, it is important to consider the amount of land in an industrial development which would be consumed by rail service. Admittedly, some of this land would be in required yard setbacks but this area could be used for parking, truck loading, or in some instances, structures—if not required for rail.

Traffic Generation

Understanding the nature and extent of traffic generated by various uses of land is important to the industrial land developer in providing for adequate roads. Small land developments may not in themselves generate sufficient traffic to create an overload of the existing road network. On the other hand, industrial plants often generate substantial traffic which must be accommodated by the road system. Standard values for the amount of traffic generated for various uses of land are not available; however, typical values, based upon experience, can be used. The traffic generated is generally expressed in terms of the number of trips per acre, or per 1,000 square feet of gross floor area.

In traffic generation studies for industrial areas, the principal measure of density is employees per acre. The operations with lowest employee density are highly automated industries or warehouses supporting fewer than 5 employees per acre. A second class is light service industry, generally located on small parcels and having 5 to 20 employees per acre. An industrial tract in a larger development with more intensive employment may have from 20 to 100 employees per acre. One of the most intensive industrial classes is office industry (research and development). An industrial site of this type may support more than 100 employees per acre. A fifth class is mixed industrial development which has a variable employee density. Traffic generation rates are indi-

cated in vehicle trips per acre and in vehicle trips per thousand square feet of floor area. (See Table 1.)

As a general rule, one lane of pavement will handle from 800 to 1,200 trips per hour within the development. The actual number of cars accommodated within these limits is a function of several parameters including street layout, traffic control at intersections, and adequacy of highways serving the site. Therefore, all complex traffic movement should be analyzed by a traffic engineer to assure adequate design.

By FRANCIS W. GENCORELLI, RA, AIA

ESTABLISHING LIAISON

In most building types, the initial step is site selection. In the new-plant project, a considerable amount of time must be spent in establishing liaison with the client's organization and explaining the relevant problems to the client's planning team. The fact that most plant construction will be done by corporate clients makes it imperative that the source of responsibility be clearly established. This will make it possible to avoid misunderstandings about the relation of the proposed type of plant to its site, to its output, and to the future potential of the business.

As the first step, an organization team consisting of responsible production and engineering people should be established. Qualified outside counsel should then be selected.

The team of internal production and engineering people should be freed from all routine duties so that they may concentrate on the new construction program. This is vitally important, since no one can do the kind of creative thinking and reacting to creative thinking that a new project calls for if he is surrounded with the routine that is a necessary feature of every management procedure.

An orientation period is necessary to tune everyone in to the right point of view. A general consensus about the project should prevail. Everyone should be made to realize that decisions on site selection and plant building design will have an immense influence on operating costs and plant maintenance. It is important that the internal organizational team set itself to gather all necessary *input information* concerning the company's past growth, so as to have available necessary documentation for the future steps in the design. (See Fig. 1.)

THE SECOND STEP—SELECTION OF PLANT SITE

To a larger degree than is readily apparent, the site has a direct influence on the ultimate efficiency of the plant through the effects of site factors on plant design and construction. The consultant should be selected before a site decision is made. In many cases management selects the plant site, pays for it, and then requests the outside consultant to design the plant. The outside consultant must then design around the site conditions. The owner and his internal organization, together with the outside consultant, have many factors to consider in the survey of possible sites: physical, economic, legal, social, site size, climate, land topography, soil conditions, availability of raw materials, etc. These are too numerous to consider in detail. They are provided for in the following Plant Site Analysis Input Sheets used by the author's firm in the past (see Table 1 and Fig. 2).

THE THIRD STEP—PREPARING THE FUNDAMENTAL LAYOUT

The design of an effective plant layout is a problem of defining and responding to the analysis.

It is a system of rational three-dimensional analysis and evaluation. From the input developed by the internal organization, the outside consultant can analyze the existing flow activity space requirements, primary and secondary adjacencies, etc. It is imperative that the outside consultant be made fully aware of the idiosyncrasies of a particular product and a number of products produced in similar processes. A plant can have a layout based on *production* or on a *process*. If a company produces a large quantity of a few products, then you function on a *product layout*. If a company produces a great number of products, each with relatively small runs but similar processes, then you design on a *process layout*. In developing a new-plant project, it is obviously very unwise to consider immediate needs only. The wise management will consider its needs on a long-range plan. The entire plant site should be laid out for at least a 25-year

period, with the particular building project built to serve only the needs of the next 5 years—all of which can only be projected from sales reports and anticipated markets. Expansion by growth can be a fairly accurate projection; however, expansion by acquisition cannot be easily determined. In one instance, a project increased by 300 percent during the construction period because product lines were added through company acquisitions.

The following is the initial breakdown of area allocations:

1. Administration
2. Employee facilities
3. Research and control
4. Manufacturing
5. Warehousing
6. Internal engineering
7. External engineering

Figure 3 shows area relationships.

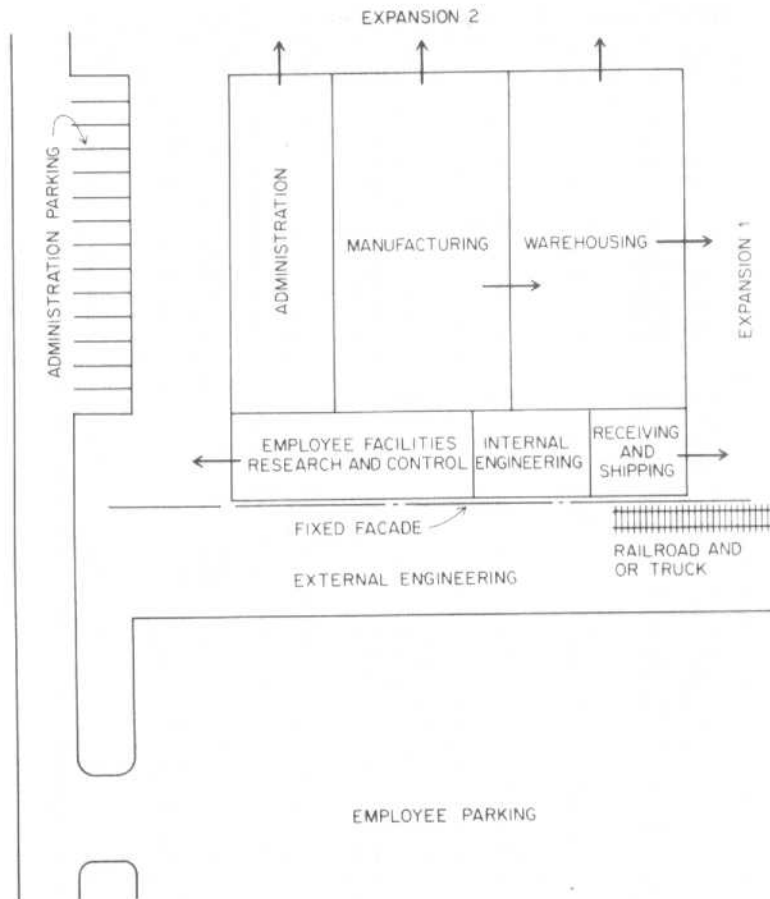

Fig. 3 Basic area relationships.

1. Administration

The following organizational relationships must be worked out before the planning of this area can be developed:

a. Reception Room

Number of seats

Receptionist—special or part of the general

office, extra duties (typing, etc.), equipment

b. Executive Area

Private Offices—number, occupant of each, size of each, furniture and equipment for each, closets

c. Departments and/or Divisions

Accounting, bookkeeping, production, etc.

d. Private Offices in Each Department

Number, occupant of each, size of each, furniture and equipment for each, closets

e. General Work Areas in Each Department

Personnel in each, equipment in each, storage requirements for each

f. Special-Purpose Rooms/Areas

Conference room

Library

Projection room

Mail and shipping

Reproduction room

Secretarial pools

Telephone equipment rooms

Hospital areas

PBX room—type of board

number of positions

IBM room

File room

Private toilets and showers

Stock and storage rooms

Rest rooms

g. General Information

Interrelationship of person and department

Clothing space

Time clocks

Water coolers

INDUSTRIAL BUILDINGS, GENERAL

Special lighting requirements
Plumbing requirements—special sinks,
etc.
Intercom requirements

Our experience has shown that a study of the requests for space by department heads in proposed administration areas has resulted in subjective judgments based on ego-oriented requirements for space rather than objective judgments of function. The space standards shown in Fig. 4 should be used in planning the administration facilities.

In order to develop plans as accurately as possible, the following program must be initiated:

1. Survey of existing personnel, furniture, and equipment
2. Determination of approximate square footage of each department
3. Space analysis interviews with department supervisory personnel to determine existing space problems, their views on future projections, and the functional adjacencies of the departments
4. Review of factors which would have an effect on both immediate and future departmental space requirements
5. Area standards recommended
6. Determination of square footage required for all departments with an itemized breakdown by type of space, i.e., private office space, general office space, and miscellaneous areas

The projected requirements developed are based on the assumption that present policies and procedures will continue to apply in the future. Obviously, the company will initiate new policies and procedures and introduce new methods of operation. However, the extent to which any such changes would affect the projected area requirements could only be conjectured. Therefore, to minimize arbitrary judgments which would tend to dilute the validity of a study, consideration should not be given to such possible eventualities.

2. Employee Facilities

Both the quantity and the quality of the product depend not only on the sequence, precision, and efficiency of the factories, tools, and machines but on the proficiency, pride, and fitness—both mental and physical—of the personnel. The development of factory design in recent years has become more and more concerned with creature comforts for the employees.

The facilities should be near the work space, so that no time is lost getting back and forth, but they should be sufficiently insulated from the sights and sounds of the work area itself so that a real change of scene is provided. If a pleasant outside view is available, it should obviously be used. (See Fig. 5.)

A clear distinction should be made between quiet lounging places and recreation and cafeteria areas. The problems are interesting, the solutions may be various, but the reigning criteria seem to be constant—cheerfulness, comfort, and durability.

The areas in this category include the following:

- Cafeteria and kitchen
- Coffee lounges
- Recreation areas (indoor and outdoor)
- Quiet lounges
- Factory men's and women's lockers and toilets
- Office men's and women's lockers and toilets
- Meeting rooms
- First Aid and nurses station

3. Manufacturing

The trend toward automation has had a profound effect on plant design. Automation reduces employee density while increasing output. In terms of building area required, manufacturing space has diminished by some 50 percent in the last 10 years for the same process. Needless to say, productivity has increased by close to 400 percent.

As discussed previously, a plant can be designed under two different concepts, depending on the product and the number of products. *Product layout* can be said to be linear while *process layout* is parallel. This can best be decided by a flow-activity study showing number of products and the quantities of each. (See Fig. 6.)

The importance of flexibility in internal construction cannot be stated strongly enough. Except in factories producing one product (e.g., automobile assembly plants), the need is mandatory. When a manufacturer is producing several products and one succeeds far in advance of the others, his plant must be flexible enough to handle this emphasis. The other product lines must be held back until an expansion program is begun.

The following is a list of criteria for production-line evaluation:

1. Ease of flow of materials
2. Degree of flexibility
3. Ease of expansion
4. Ease of personnel movement
5. Ease of supervision
6. Least initial investment

The outside consultant, working with the organizational team, can synthesize the above criteria to produce an effective plant layout. In any plant design, it is essential that the outside consultant have available the detail for the present and projected manufacturing machinery. From this, the experience, knowledge, and imagination of the designer will yield the dividends. As used in the design of the administration spaces, templates or space standards per machine must be established, arranged, and rearranged to produce the best organization of equipment and spaces.

4. Research and Central Facilities

In the modern plant areas for research (product development) and control, laboratories are a must. As the size of the plant—and, in turn, laboratory facilities—increases, a strong case can be made for separating the two, which are basically similar installations. In the case of chemical, pharmaceutical, and dermatological plants, adjacent to each research laboratory should be a pilot plant installation which can produce, on a smaller scale, simulated manufacturing processes. In extremely large manufacturing plants, the research and product development facility should be in a separate building.

Flexibility is mandatory in the layout of research and development facilities. Any research program can be maneuvered to concentrate on a particular channel once the manufacturing advantages of a particular area of research are promising. To effect this, all or most of the research personnel will be concentrated on this product development. An inflexible laboratory layout can preclude this possibility.

It is becoming more and more prevalent in industrial research and product development installations for a large company to take research contracts from smaller companies in

INDUSTRIAL BUILDINGS, GENERAL

Fig. 9 Location of external engineering.

the same industry. With the scarcity of professionally qualified research people, this may be the only way for a relatively small industrial firm to get the necessary research work done.

Control laboratories, on the other hand, must be immediately adjacent to the manufacturing space and in many instances located in the manufacturing area. Recent federal regulations place an inspector in the manufacturing area, and he, therefore, is readily available to the control facilities.

5. Warehousing

The warehouse is the first area to feel the growing pains and therefore must be designed to signal the anticipated expansion program. It must be compressible. As the raw materials and packaging materials supplier simplifies his materials handling problem, so he creates

a stocking problem for the manufacturer. Manufacturers, realizing the economies of carload or large-lot purchasing, are forced to make large capital investments in warehouse facilities in order to take advantage of these buying economies. There is, however, a point at which the law of diminishing returns steps in and no further economies can be expected.

With the increase in automation control of a warehouse, the concept of a public warehouse becomes more realistic. Where the product permits, a completely flexible warehousing operation should be used. Not all the buying is done at the same time, and it is possible that, as raw-material needs increase, the seasonal storage of finished products may be on the decline. A flexible warehousing concept would permit intermingling of raw materials and finished products and create an efficient though seemingly unordered warehouse.

This scheme has worked, especially in a preexpansion condition. The traditional warehouse location should also permit initial expansion of manufacturing into its area. Since warehousing is the least expensive capital construction, it is reasonable to build the warehouse after manufacturing has expanded. Rarely does the structural layout differ in manufacturing and warehousing.

6. Internal Engineering

The single greatest error made in plant design is the placement of the internal engineering facilities. Invariably the inexperienced designer will centralize the heating and air-conditioning plant. But what is today centralized may, tomorrow, be right smack in the middle of your expansion direction.

The centralization concept grows from a desire to cut down the service runs of this equipment. It is a false economy. In an earlier diagram the use of a fixed facade, where no expansion takes place was pointed out. The internal engineering facility should be placed in a linear relationship to this fixed facade, and preferably at its extremity. What is extreme at first construction is centralized in your future expansion.

In many industries the development of rooftop combination air-conditioning and heating units is the answer. However these units are not developed for highly sophisticated climate control and often prove too limiting. They should only be contemplated where comfort conditions (75° to 80° dry bulb, 40 to 50 percent relative humidity) are adequate. Where a boiler plant is required for process work, its dual use for heating should be carefully analyzed. A complete engineering feasibility study is required to determine what system or systems should be utilized. (See Figs. 7 and 8.)

It is most important to build internal engineering spaces 100 percent larger than initially required. Adequate space for mechanical and electrical installation is a prime and vital consideration in industrial design.

7. External Engineering

By *external engineering* I mean all the outside utilities and storage facilities required for a plant to operate properly. Parking, truck docks, tank farms, sewerage disposal plants, electrical transformer pads, pumping stations, water storage facilities for sprinkler systems, and industrial waste disposal plants are a few of these requirements. (See Fig. 9.)

Since these are by nature permanent and expensive installations, they should not be placed in the way of any possible expansion. As in the case of the internal engineering, this external engineering facility should be placed along the fixed facade.

By RICHARD MUTHER

Features most likely to be involved in a layout problem include:

- Special or general-purpose building
- Single or multistory construction
- Shape of building
- Basement or balcony
- Windows
- Floors
- Roofs and ceilings
- Walls and columns

In addition to these, features of the site on which the building stands often affect the layout. Where this is so, the layout engineer must of course include them in his planning. These site features include:

- Rail lines and siding
- Highways and roadways
- Canals or streams
- Bridges
- Yard areas for storing, parking, lawn, gardens
- Outbuildings, such as storage tanks, water tower, well, pump house, incinerator, dump or burning area
- Platforms, docks, ramps, pits, truck or rail wells

SPECIAL OR GENERAL-PURPOSE BUILDING

The layout engineer should decide right away whether he wants a building custom-made or "bought off the shelf." Special buildings generally cost more and are less negotiable. They also have a way of becoming out of date as the product and facilities grow or shrink or change with new conditions. Yet, for many industries special buildings are essential if the plant is to operate economically.

Plants having relatively simple forming, treating, or assembly operations, as is the case with most consumers' goods industries, favor the *general-purpose building*. Here is the general type of building that can produce several different products with equal ease. Generally, this building is more permanent than its equipment or layout. The initial cost is less because of standard designs, standard building materials, and regular construction methods. These buildings can incorporate—just as well as the special plant—the "standard" good features that an industrial building should have, regardless of the type of production. In addition, general-purpose buildings can be converted readily to new products and equipment, to changing production requirements, or to new owners. This adaptability and resale potential gives the multipurpose building the edge. This means: use a special building only when necessary. But layout men can check this decision by reviewing the following list:

Use *general-purpose, or multipurpose, building* when these following items are important:

- Initial cost
- Possibility of selling it later for profit, a better location, foreclosure

- Frequency of changes in products, materials, machinery and equipment, processes or methods
- Speed of getting the layout into production

SINGLE OR MULTISTORY CONSTRUCTION

Early factories were generally three or four stories high. Because of limited transportation facilities they had to be built in cities, where land costs were relatively high. Also, their builders who used brick had to make walls thick enough to stand up. Therefore, they reasoned, "Why not use this structure to support upper floors?"

With the coming of inexpensive and widespread transportation for employees and of steel reinforcing or supports for buildings, companies began to build out of town. Land values were lower and the plant could spread out. Today's trend toward large one-story buildings is thus a product of changing conditions.

This does not mean that every new plant should be one story high, as some industrialists advocate. Plants built around a higher-than-one-story process should certainly have upper floors. Manufacturers who decide the advertising value of a downtown plant is important will have to use several stories to utilize their land economically. And we cannot understate gravity, even though power costs may be low. Again, when products are small and relatively valuable, as in diamond cutting or watch-making, there is considerable saving by concentrating rather than spreading out.

Use *single-story construction*, possibly including balconies and/or a basement, when the following conditions exist:

- Product is large, heavy, or relatively inexpensive per pound
- Weight of equipment causes heavy floor loads
- Large, more or less unobstructed space is needed
- Land value is low
- Land is available for expansion

- Product is not adapted to gravity
- Erection time is limited
- Frequent changes in layout are anticipated

Perhaps the most universally economical plant today is the so-called one-and-a-half-story plant (see Fig. 1). This is basically one story but may include balconies or basement.

SHAPE OF BUILDING

Early buildings were narrow because they needed natural light. They expanded by extending their ends and by adding cross buildings in a rectangular fashion. Today artificial lighting is relatively less expensive. The number and frequency of production changes are greater. Therefore, emphasis today is on plants that are relatively square and not "honey-combed" or obstructed by walls. Such plants are built in rectangular sections, and expansion is by building additional sections onto the sides or end (see Fig. 2).

Where land is limited, as in river valleys—or where property lines run at curious angles—the building must suit the limitations of the land itself. Dirty, odorous, noisy or vibration-producing operations should be segregated in separate buildings. Hazardous operations with fire or explosion possibilities also fall in this class. And service buildings used for administration, sales, personnel offices, and power plant—buildings that do not directly participate in the flow of production—can also be set apart. Use the following lists to guide your decision in the matter of *building shape*.

Use a relatively *square building* when there are:

- Frequent changes in product design
- Frequent improvements in process
- Frequent rearrangement of layout
- Restrictions on building materials or savings desired in amount of materials used (see Fig. 3)

Use *other shapes or separate buildings* when there are:

- Physical limitations of the land
- Property lines at curious angles

Fig. 1 Features of the one-and-a-half story building: (a) Rail siding with car floor at level of plant floor. (b) Truck tailgate level with plant floor. (c) Shallow ramp down to basement; low ramp up to floor level. (d) Windows for basement lighting. (e) Balcony or mezzanine for supporting activities and/or production. (f) Two-story office building with entrance at ground level.

Fig. 2 Planned expansion of early and modern plant buildings.

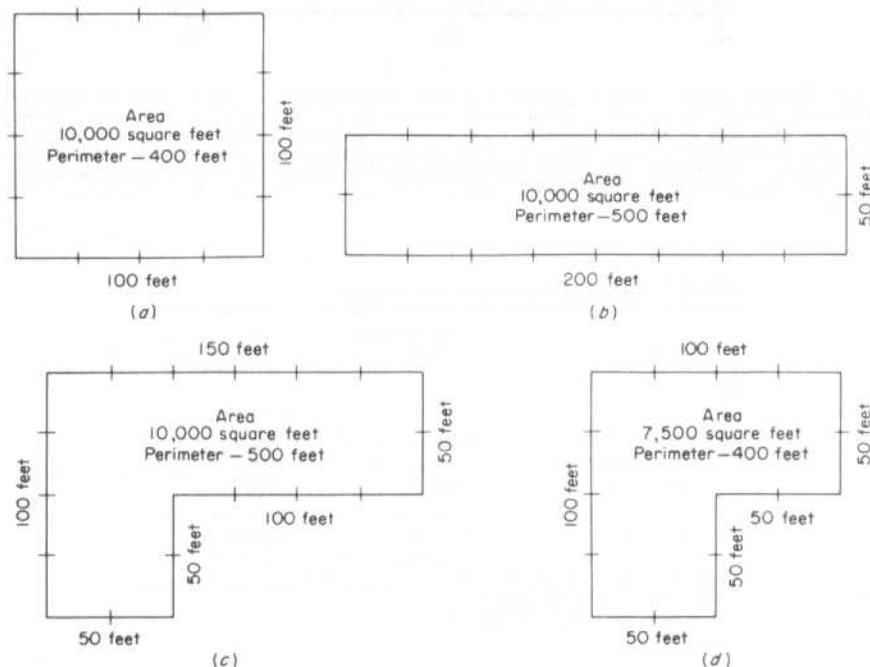

Fig. 3 Compare materials needed in the side walls of the four plans shown. Three plans, (a), (b), and (c), are for the same size plant, 10,000 sq ft. But of the three plans, plan (a) has the shortest perimeter wall and will use less materials than will plans (b) and (c). Plan (a) has one-third more floor space than plan (d), but the same wall area. Where material saving is of prime importance, the square plan should be advocated. (Factory Management & Maintenance.)

Fig. 4 Basic use and arrangement of basement and balcony.

- Buildings that house operations that cause dirt, odors, noise, vibration
- Buildings that house operations not part of production
- Buildings that house operations susceptible to fire or explosion

BASEMENT OR BALCONY

A plant can hardly avoid having a basement when it is built on land that slopes. And this has very practical advantages. Some plants are built on the side of a hill for the express purpose of having motor-vehicle entries to each floor. This offers the advantage of entry to two or more levels with a minimum of ramp construction, and it allows receiving at one level and shipping at another with flow through the plant in a U-shaped path in the vertical plane.

If you decide to have a basement, or if your new building has a basement, check to be sure it has these *desired basement features*:

- Ample headroom
- Good ventilation
- Sound foundations
- Ample lighting
- Waterproofed walls
- Floors free of groundwater seepage or flooding

Partial basements may be of real value when a basement for production purposes is not needed. Heating plant, compressors, pumps, and other auxiliary equipment are well suited to location off the production floor. This also applies to other services such as washrooms and locker rooms, toilets, transportation aisles for material handling or personnel, storage for slow-moving parts, overruns, inactive tools, dies, fixtures, patterns, and the like.

Certain processes may need a basement, as in large stamping-press work where special foundations are desirable and scrap collection is a big factor. It may be easier to excavate and build up machine foundations than to break out pits or install each foundation from floor level. Especially tall equipment may be placed in a basement so that its working level will be on the main floor. In fact, there are some plants whose main operating floor is little more than sheet-metal plates for machine tenders to stand on; all the machinery rests on a basement floor.

On the other hand, where ample headroom over equipment is required, the layout should not be confined in a basement. Extremes of this are in large equipment manufacturing or ship construction. Here cranes and large materials prohibit basement use. Yet these industries often make use of balconies for their smaller, lighter work (see Fig. 4)

Typical cases where balconies are used include:

- Subassembly operations with final assembly of large units on ground level
- Assembly operations with heavier forming machinery below
- Light-machine operations with heavier machines below
- Treating operations with forming operations and assembly of bulky units on ground level
- Supporting activities of all kinds to men, materials, or machinery—storage, washrooms or locker rooms, production offices, and the like—that can be kept off the production floor
- Operating or servicing upper parts of tall, high machinery
- Material storage and preparation area, including bulk material blending or packing-box making and distribution

WINDOWS

Old factories had to have small windows because of the cost of construction. The introduction of large, steel-sash windows brought their cost down. Today windows are often cheaper than walls. On the other hand, windows make buildings more subject to changes in outside temperature. Plants having products or processes especially subject to changes in temperature, light or humidity find it better to have no windows at all. Chocolate factories, for instance, have to watch temperatures. Many of these plants control this condition by ventilating and air conditioning. Their light is artificial. Other plants reject windows because of the dust they let in, even with slightly pressurized air inside.

The layout man who must contend with windows recognizes that they may both help and hinder his arrangement (see Fig. 5).

The following is a list of points to check where windows may affect the layout:

- Brightness or glare
- Angle of light—morning and evening, winter and summer
- Heat effects to personnel and/or materials from sun on windows
- Resistance to wind, shock, fire, acids, rust
- Drafts on personnel when opened
- Access for washing or repair

FLOORS

The levels and strengths of floors are the most important floor influence on layout. Adjoining buildings, and even those far removed that may someday be connected to the main plant, should have floors at the same level. Handling systems can then be tied in without ramps or elevators. As for floor strength, it should be checked with the architect.

Early factories had dirt or wood floors. Today, various combinations of steel and concrete give the least expensive floor. It wears well; it is strong and easy to clean. But workers who stand or walk a great deal object to the hardness of concrete floors. Also, certain materials dropped on concrete are likely to be damaged. Concrete is difficult to cut into to rearrange wiring or piping in the floor.

Workers' foot fatigue is overcome by providing wooden or rubber mats. The objections of damage to dropped parts and difficulty of rearrangement can be met by covering the concrete with wood block, wood flooring, or composition block or coating. The following list gives floor characteristics desired, though no floor will have them all:

- Various buildings at the same level
- Strong enough to carry machines and equipment
- Made from inexpensive materials
- Inexpensive to install
- Immediately ready for use
- Resistant to shock, abrasion, conducting heat, vibration
- Not slippery under any condition
- Noiseless and sound absorbing
- Attractive to the eye
- Numerous colors available
- Unaffected by changes in temperature and humidity, or by oils, acids, alkalies, salts, solvents, or water
- Odorless and sanitary
- Resilient enough to seem soft underfoot and to minimize damage to articles dropped on it

(a)

(b)

Fig. 5 Good natural lighting relates to both window and roof design. Windows in a monitor roof (a) give good uniformity and intensity. The use of roof lighting obviates the need for wall windows and is useful in large building areas and where there will be future expansion. The windows in a sawtooth roof give reasonably uniform light, especially when arched. But they cast shadows (b). At the left the worker stands in his own shadow; at the right his machine blocks the light. Nevertheless, where direct sunlight should be kept out, northerly directed windows of this type are not out of order. (From George Nelson: "Industrial Architecture of Albert Kahn, Inc.," Architectural Book Publishing Co.)

TABLE 1 Generally Recommended Ceiling Heights

Type of production	Without overhead installations*	With overhead installations†
Small-product assembly on benches; offices	9-14 ft	10-18 ft
Large-product assembly on floor or floor fixtures	Maximum height of product + 75%	Maximum height of product + 125%
Small-product forming	Height of machinery + 100%	Height of machinery + 150%
Large-product forming	Height of machinery + 125%	Height of machinery + 125%

* Other than lighting and sprinkler.

† Air ducts, unit heaters, conveyors, etc.

- Easy to fasten machines and equipment to
- Will dissipate static electricity and is non-sparking when struck
- Easily kept clean
- Large sections easily and quickly removed and replaced

ROOFS AND CEILINGS

Roofs and ceilings affect layouts chiefly by their height above the floor. Table 1 has some generally recommended heights for use as a rule of thumb.

Roofs and ceilings are also affected in many cases by the type of construction. Figure 6 shows the several types of roof construction most commonly used.

The usefulness of overhead space may be limited by what can be attached to the roof or ceiling. Very few plants hang their machinery from the roof or ceiling. But a great many suspend material-handling equipment, service pipes or wiring, and other equipment. Such considerations as natural light, heat conduction, and dust accumulation also relate to the type and condition of the roof.

WALLS AND COLUMNS

Unlike early plants which depended on thick stonework or masonry to hold up their walls and roofs, modern buildings place their load on beams and supporting structures, generally of steel or reinforced concrete. This way, the column carries the load and no wall is needed, except to keep out the elements. This is a great help to production for it means large, unobstructed working areas.

Inner walls today are only partitions. When certain operations must be segregated, partitions that are generally built up in standard sections can easily be installed or removed. They can be made as high as necessary to shield or protect the area or can be suspended from the ceiling. This latter type of baffle keeps the floor area free but holds fumes, noise, heat, and the like from circulating throughout the building.

One feature easy to overlook is the size of openings in walls. Doors that are too low or too narrow, for example, will limit the size of material-handling equipment.

Even without interior walls, there is still the obstruction of columns used for roof sup-

Fig. 6 Typical types of roof structures. (a) Truss. (b) Sawtooth. (c) Monitor. (d) Bowstring truss. (e) Concrete arch. (f) Three-bay, or high-low, gable. (g) High crane type. (h) Cantilever.

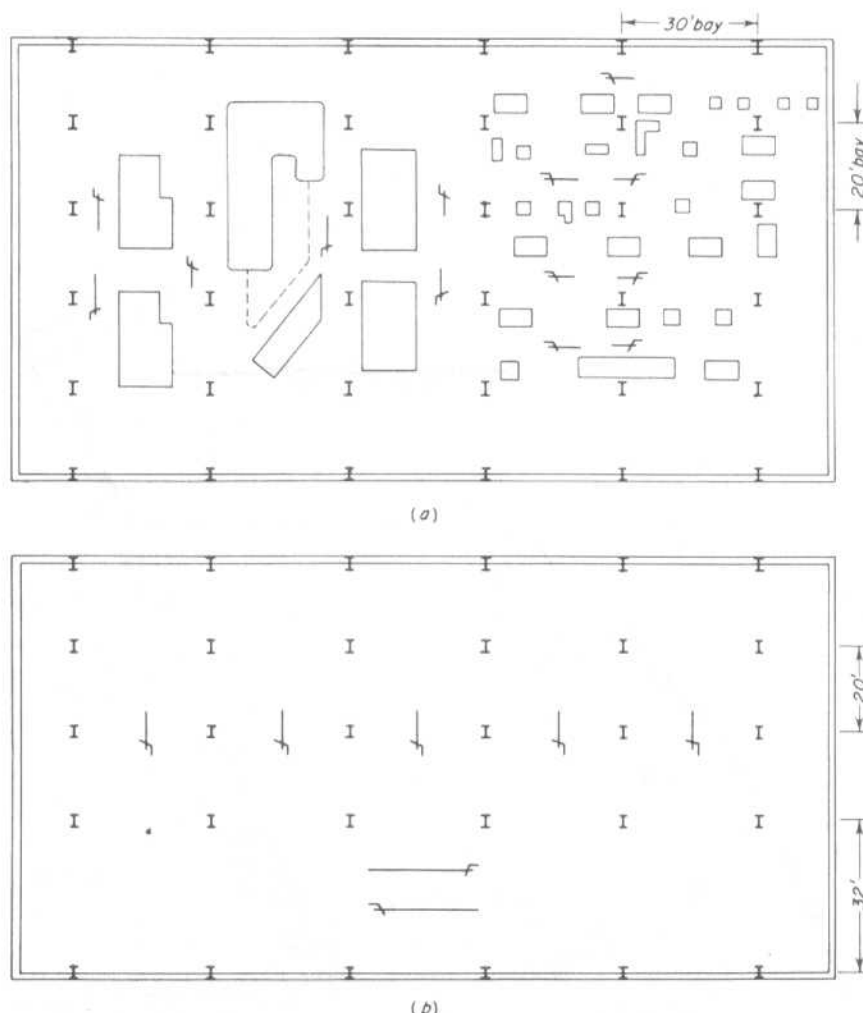

Fig. 7 Column spacing. (a) Large operations line up in wide bays; small operations in wide or narrow bays. (b) Combination of two different column spacings - to take advantage of flow lineup with wide bays.

port to plague the layout man. These columns interfere with spotting of machinery, aisles, storage areas, and overhead handling equipment. Columns cause two basic problems:

1. The way they line up tends to confine the basic flow patterns.

2. Their individual location limits the location of all facilities, especially large equipment.

The layout man will undoubtedly want to line up major aisles, stock shelves, and service lines with the columns. Large operations will lie lengthwise down through the bays with the wider spacing. Smaller materials and equipment will generally run in the narrowed spacing (see Fig. 7).

As for columns that act as obstructions to the spotting of individual machinery and equipment, the layout man must plan a column arrangement that will tie in with his layout. Yet a lot of unnecessary money can be put into a building that calls for too-wide column spacing. Some layout men admit they always consult their architect and then call for about 15 percent greater spacing than he feels is economically justified. Another layout problem is to take whatever column spacing and arrange-

ment is planned or already exists in the building and use it to best advantage. By experimenting with various alternative plans, it is often possible to juggle a neat arrangement of machinery, equipment, and supporting activities into the column layout. Then the layout man can often use the columns to advantage as follows:

- To support overhead handling equipment
- To brace up storage racks
- To fasten or fence in treating equipment
- To support balconies, catwalks, auxiliary service lines, instrument panelboards, and machinery itself

Since columns mean lost floor space, place against them and in between them other non-productive equipment that takes floor space (drinking fountains, drains, firefighting equipment, time clocks, and the like).

SITE FEATURES

Features of the site are important in any layout that involves expansion of buildings or a layout of more than one building. Rail lines and sid-

ings, roadways, canals, and outbuildings may have to be provided, or, if they exist, may limit the layout or may have to be moved or altered. For railroad car and highway truck dimensions that may affect building features, see the data in Tables 2 to 4.

The location of an underground storage tank will limit construction or heavy outside storage in that area; dust and smoke from a foundry building should blow away from the main administration building; rail siding curves can occupy an unusually large area. These and many features of the site may be involved in any layout other than those strictly within one building (see Fig. 8).

RAILROAD CLEARANCES AND FREIGHT CAR DIMENSIONS

Normal Clearances Nominal clearances are required as a matter of safety between locomotives and cars, and structures near tracks. These are averages for straight track—some companies and states require more as noted. The clearances are based on standard 4-ft 8½-in. track gauge. (See Figs. 9 and 10.)

Industrial

INDUSTRIAL PLANTS

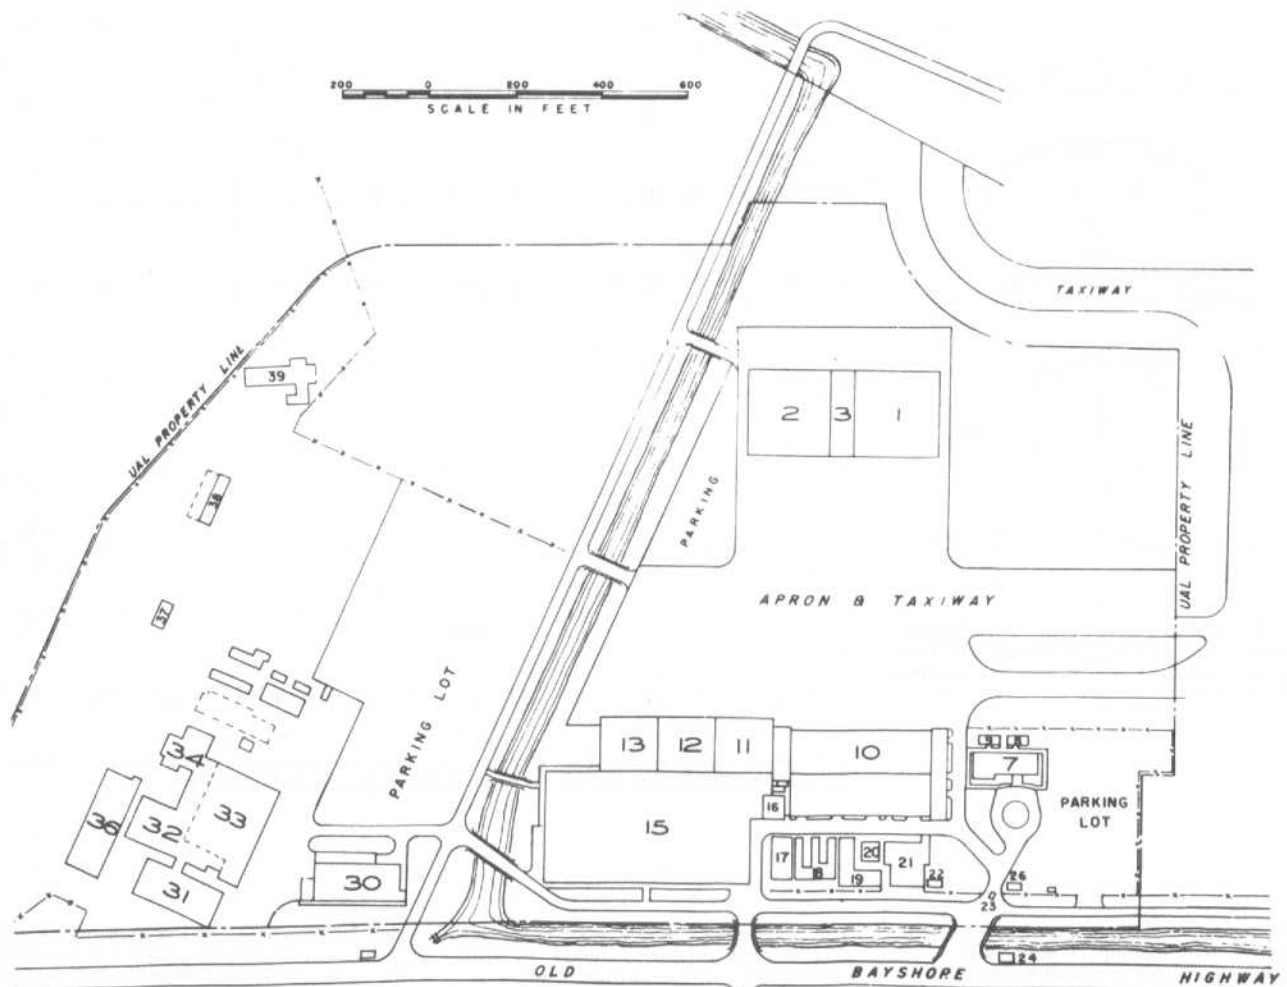

Fig. 8 External features such as highway, stream, roads, and property lines all influenced the arrangement of this site. This is the arrangement of the maintenance and repair facilities of an airline. (United Airlines.)

In planning the arrangement of buildings, they should be laid out in relation to the overall site just as the individual machine and equipment layout relate to the building. A long-range plan of development for the entire site should be obtained so that buildings can be properly integrated with each other.

TABLE 2 Freight Car Dimensions

Type of car	A Length over strickers, avg.	B Inside length		C Overall width, avg.	D Inside width		E Overall height, avg.	F Inside height		G Floor height, avg.	Level full capacity, avg. cu ft	Tare weight, avg. lb
		Min.	Max.		Min.	Max.		Min.	Max.			
Flat	53'-0"	36'-0"	60'-0"	10'-3"	8'-6"	10'-6"	8'-6"	4'-8" avg.	3'-11"	3'-11"	1,775	48,700

Largest and heaviest tandem-wheel, dual axle, semitrailers and full trailers	50-56

* From Modern Materials Handling.

TABLE 4 Highway Truck Dimensions

Type vehicle	Height	Length	Width
Medium trucks	9½ ft	34 ft	7 to 7½ ft
Large trucks and trailers	13 ft max.	45 ft	7½ ft to 8 ft

Fig. 10 Typical railroad car data.

Clearances for Curves Allowances must be made on curves, due to the increase in effective width of equipment. The increase inside curves depends on the distance between truck centers and the increase outside curves depends on length beyond trucks. Tilt of equipment toward inside of curve due to banking of rails must be included as well as any slewing action caused by tire wear and other lateral

play. As a rule, the front of a locomotive will govern effective width for a foot above top of the rail and the rear of the cab for the remainder of the height. For preliminary calculations of clearance outside curves, it will usually be ample to allow 1 in. per degree of curve plus 2 in. for all curves. For inside clearance, a general allowance of 1½ in. in addition to the middle ordinate distance for a 45-ft

chord will be sufficient.

In cases involving new construction, a sketch of clearances should be submitted to the railroad for approval.

Tracks Entering Building Some railroads permit special clearances when tracks enter coal tipples and buildings. Railroad company engineers can be contacted for requirements.

Classes of Research Facilities

The Public Health Service divides research facilities into four classes: *Class A Laboratories* are designed with maximum capability for conversion from one program use to another. These are primarily intended for research in the basic scientific disciplines of biology, chemistry, and some aspects of the physical sciences. The design criteria are intended to protect the integrity of individual research programs from interference by other research within the same structure and to reduce the possibility of infection or toxic hazards to personnel in present or future research projects.

Class B Laboratories are designed with limited capabilities for conversion. This laboratory class is suited for a narrow range of activities in such disciplines as the social sciences, psychiatry, public health work, or epidemiology and could not be used for research involving the basic disciplines of chemistry and biology without major alterations in the heating, air conditioning, ventilation, plumbing, and electric power systems. The original design provides for individual room temperature control.

Class C Facilities are designed for research support, including such structures as stock barns, animal pens and runways, storage sheds, and utility structures. This class is considered functional without utility services and does not require noncombustible construction.

Class D Facilities are designed for special research functions that require a specialized environment. Their structural provisions render them inherently unsuited for conversion. The design criteria must be determined for each project. This category includes biotron or betatron buildings, hyperbaric chambers, germ free animal production facilities, biohazard control facilities, and other research buildings with specialized functions.

Planning

A health research laboratory building must have the capability to satisfy research operational needs, allowing for variation both in research projects and in occupancy, for at least 10 years. Planners and designers must recognize that the structure will have to meet a variety of functional needs, rather than the specific requirements of a single group of occupants.

The most effective administrative device for planning a health research facility that will meet both current and future requirements is a written description of the total functional needs of the program(s) expected to operate in the building. Generally called the Program of Requirements (POR), this written description lists the functions and operations that will be housed in the structure, the design criteria

for those functions, and their space needs. It also provides information on the projected staffing and the equipment which will be needed in the building. This written Program of Requirements is most valuable if it is prepared before any drawings and preferably should precede the preparation of space function relationship diagrams.

Space Blocks Where the first full occupancy staff is available to advise on the functional requirements of the structure, planning and design can be directed to smaller units of space such as individual laboratory modules, suites, or departmental laboratories. Where only a small staff is available for planning the total long-range scientific research program and its space needs, the administrator must approach planning and design with a different philosophy.

In this situation, it may be best to consider the research programs in terms of functional space blocks ranging from 3,000 to 6,000 sq ft each. The size of the space planning blocks can be determined by using the POR to assess the anticipated programs and staffs that will occupy the building in the first phases of its occupancy. Generally, a space block is selected that will accommodate a group of two or three of the smaller programs, satisfy the moderately-sized programs and that, in multiples, will meet the needs of the proposed major operational units.

For example, if the POR indicates that 4,000 sq ft roughly equals the special needs of each of several functions, that there are a number of smaller functions requiring 1,000 and 2,000 sq ft each, and some larger functions with space requirements of 6,000, 8,000, 10,000, 12,000, and 16,000 sq ft, it is a reasonable approach to adapt a 4,000-sq-ft space block as a planning unit. The utility systems, the circulation systems, and supporting elements are planned to make each one of the 4,000-sq-ft space blocks self-sufficient. It is then possible to assign one medium-sized program element to a space block, assign multiple smaller units to a single space block, and use several space blocks for one major component.

Space planning strategy is associated with the development of space function bubble diagrams. These diagrams can be used to relate the individual space blocks functionally and to pool several space blocks to handle one major program.

Building Shapes Planners and designers sometimes try to meet laboratory functional needs with esoteric shapes and dimensions. Although circles, hexagons, and tall slim towers may have esthetic appeal, none of them are as efficient as, or have the capability of, rectangular designs. Rectilinear laboratory equipment and office furniture and the anticipated continual interplay between rooms call for utilitarian solutions. Buildings with simple rectangular configurations, commensurate with standard laboratory equipment and furniture, and with unrestricted accessibility to mechanical utility systems, are the easiest to adapt to the changing needs of research.

Flexibility and Capability The term *flexibility* is frequently used in discussing the design characteristics of research laboratory buildings. However, *flexibility* should be interpreted with caution because most research laboratory structures should be designed with the concept of capability in mind. The structure's capability to meet varying ventilation needs for different research functions, its ability for temperature control of varying heat loads, its capability to meet the needs for fume hood, air supply, and exhaust in different concentrations with time in various areas in the building are all critical. The ability to supply electric power in high concentrations to any localized area without the need to reposition electric distribution lines within the building is a measure of the facility's capability to meet the needs of the research program that will eventually occupy the building.

Flexibility is emphasized by considering the possible location and utilization of chemical fume hoods. Saying that the building can provide for 50 chemical fume hoods is meaningless unless it is specified whether only up to a maximum of 10 can be utilized on any one floor, or whether the design capability is such that all 50 can be installed and used on one floor. A more detailed examination of the building's capability might reveal that no more than two hoods could be installed in any one laboratory module due to the limitations on supplying and exhausting air in that particular room. This approach contrasts with the method of determining the location of hoods according to requests by the initial occupants of the building. Providing supply and exhaust hoods in specific areas or rooms according to desires of the first occupant limits the capability of the building for future occupants.

THE LABORATORY BUILDING¹

To a large extent the design of a laboratory building will be dictated by the heating, ventilating, and air-conditioning systems, and the utility distribution layout. If these factors are carefully planned first, the laboratory building design will be an efficient one, and it will still be possible to plan for structural flexibility and growth needs as well as for engineering capability.

The module plan is the most useful for the design of health research facilities. This section will briefly discuss how various groups have met some of the challenges of research laboratory design, using the module as the basis for a grid pattern. Experience with industrial and academic laboratories can prove instructive for those working with health-related facilities.

Planning for Flexibility and Growth

Architects have been trying to develop comprehensive systems which will relate the needs

¹Health Research Laboratory Design, National Institute of Health, U.S. Department of Health, Education, and Welfare, Washington, D.C., 1968.

¹This section is based on an article by Jonathan Barnett in *Architectural Record*, November 1965, volume 138.

RESEARCH LABORATORIES

of various departments and disciplines and provide ways of sharing certain facilities, such as lecture halls and teaching laboratories. In addition, such a system can provide an architectural recognition of the increasingly interdisciplinary nature of much scientific research: for example, by placing bio-physics between biology and physics, with the capability of expanding in either direction.

The system developed by Sir Leslie Martin (Fig. 1) consists of a *regular grid* derived from considerations of space, lighting, and an integrated system of structures and services. The grid forms 35-ft squares separated by 5-ft strips. Ducts and services can be introduced at any point within these strips. The system is also divided vertically, with large areas such as lecture halls, workshops, and special laboratories for heavy equipment at the lowest level, teaching laboratories above, and research areas on top. As shown in the drawings, the grid can be applied to a site, giving a rough indication of present areas and future expansion possibilities. Architectural development can go on in stages, in relation to the grid, forming segments of a larger system rather than single buildings.

Industrial Laboratories Industrial research facilities do not yet require such a comprehensive solution. Industrial laboratory space is likely to be more uniform than a university or government facility. The range of research is relatively narrow, and, as there is no strong tenure system, industry is less likely to design a laboratory around the requirements of a particular scientist. At present, therefore, industry tends to think of new laboratory space in terms of adding blocks of a set size and type. The long-range outlook, however, is probably toward the more flexible approach already employed by the universities.

University Laboratories The Chicago office of the architectural firm of Skidmore, Owings and Merrill has been working on the development of comprehensive laboratory grids for universities (Fig. 2). Such grids lend themselves to growth of almost any shape and in almost any direction.

Planning the Laboratory Complex

There are four basic areas in any laboratory complex: the area for research itself; the administrative offices; general support facilities, such as an auditorium or a cafeteria; and service facilities, such as shops and the boiler plant. The addition of teaching requirements does not change this pattern significantly. Elementary science courses are taught in special teaching laboratories and demonstration lecture halls; but more advanced students are quickly integrated into the research organization.

The chief difficulty with the nonresearch elements is to prevent them from interfering with the design of the research areas. A badly located auditorium or boiler plant can strangle expansion and interfere with efficient operation. The most comprehensive method of avoiding such difficulties is the overall planning grid.

A master plan must make provision for independent growth of all four of the basic elements of the laboratory complex, either through a campus type of development or through sufficient articulation and separation of each area.

Research Areas The research portion of the laboratory is itself divided into several basic elements. Most research areas require desk space as well as bench space; and many experiments require some sort of controlled environment, with closely regulated temperature and humidity, or the elimination of outside contamination. Controlled environment installations and other ancillary facilities frequently cannot be accommodated within the ordinary research areas. In addition, scientists frequently wish to have conference rooms directly associated with research, and there are usually some fairly extensive storage requirements.

Construction Factors Economy of construction can conflict with efficient operation. Bench areas and special installations require elaborate piping services and air conditioning; desk space, conference rooms, and storage areas do not. Bench space and special installations are usually fairly large areas; desk space, conference rooms, and storage form smaller units. In terms of economy, it makes sense to group like functions and like areas, and to separate desk space and conference rooms from research. Unfortunately, most scientists prefer desk space to be near their research, and special installations need to be associated with research as well.

The design of teaching laboratories provides an analogous situation, with less need for desk space but a requirement for preparation rooms. Resolving these contradictory requirements, while still providing for flexibility and growth, is perhaps the most difficult problem in designing a laboratory.

The possible solutions range from placing all desk space in a separate building to incorporating all offices within the laboratories. The degree of separation possible, and the ratio of one type of space to the other, varies from discipline to discipline. Figure 3 shows some of the possibilities, within a flexible space system which can be used for either purpose.

The comparative study of eight different teaching laboratory layouts (Fig. 4) assumes that all office space is located in a separate wing. Each method of organization is evaluated in terms of economy of construction and mechanical equipment, circulation, and flexibility.

A comparison of four basic types of industrial laboratories is shown in Fig. 5. The first one places the desk space within the laboratory itself. The second places the offices on one side of the corridor and the laboratories on the other. The third plan provides core laboratories and perimeter offices; the fourth provides a peripheral corridor and interior laboratories, with the desk space again incorporated in the research area. These four plans are representative of standard practice: most laboratories will be found to conform to one or another of these basic classifications.

There are, however, other possibilities. Eero Saarinen's design for the IBM Research Headquarters in Yorktown Heights places both laboratories and offices within a peripheral corridor system. If one accepts the concept that all working accommodation should be interior space, this is a highly efficient and consistent method of organization.

Some laboratories are organized as towers, rather than horizontally. Ulrich Franzen's laboratory tower at Cornell (Fig. 6) also provides interior accommodation, with laboratories that can be entered either directly from the corridor, or through the offices. Vincent G. Kling's science building at Barnard College is a tower, as are, of course, Louis I. Kahn's Richards Medical Laboratories at the University of Pennsylvania. Kahn's first towers provide completely undifferentiated space, which can be used as laboratories, offices, or corridors. The later towers have desk space around the periphery on some of the floors. The plans of both of these buildings are also illustrated in Fig. 6.

UTILITY DISTRIBUTION

General

Utility services within a research laboratory building require a great deal more emphasis than is customary in the design of the average building. Heating, ventilating, and air conditioning systems and the multiple pipes of the various laboratory services such as water, gas, vacuum, and oxygen create a demand for cubic space as well as floor space. In more recent designs, utility systems have taken a higher percentage of the gross area, with consequent reduction in net space. This special aspect of the research laboratory building sometimes comes as a surprise to architects and engineers whose experience has been mainly with commercial buildings, which need much less utility service capability. Associated with this need for additional space for utility services is the need to provide functional space for the unseen occupants of the building: maintenance and operating engineers, and the craftsmen who provide for the continual changes and adjustments in utility systems which mark an active research program.

Fig. 1 Studies by Sir Leslie Martin of a comprehensive planning grid for university laboratories and of the type of development that can be based upon it.

(a)

(b)

Fig. 2 (a) Laboratory planning grid by Skidmore, Owings and Merrill. A system of square bays which accepts either a diagonal or a rectilinear planning grid. Column clusters mark out circulation areas or service shafts. (b) A building unit in this system which employs a diagonal grid, and some laboratory arrangements that would be possible.

Selection of Systems

Selection of the utility distribution systems strongly influences the configuration, design, and cost of a research laboratory building. The type of utility system used should be selected as early as possible in the planning process, always before the room arrangement is fixed. Room arrangement and equipment location should follow the utility distribution pattern once this has been standardized. Arranging rooms and equipment according to the preferences of the first occupants usually results in costly, complicated utility distribution systems.

Planning a nonstandard room arrangement makes it difficult to visualize—without elaborate mockups—the configuration of space and equipment in the completed building. Then too, successive occupants are not always happy with the room arrangements selected by the first occupants. The rearrangement of plumbing and duct systems to meet preferences of successive occupants is usually costly unless these systems are installed on the standard repetitive pattern. Then a minimum of time and materials is required to rearrange the ventilation, lighting, and the plumbing and draining systems.

Standard Configuration

Utility services should be laid out with an identical configuration for every floor. This layout should be designed to meet the capability needs of the programs that will occupy the building over its life and with appropriate consideration of costs. Where it is not practical to provide an identical layout in each floor, a standard utility layout should be established for the floor which requires maximum utility services and this standard used for all the other floors, with deletions made where it is anticipated the services will not be needed for

a considerable time. The arrangement of utilities should be such that installation of missing portions of the plumbing and duct systems can be made with a minimum of labor and materials.

It may be difficult for the architect and the initial user to accept an arrangement of space based on a standard utility and mechanical system distribution system rather than on the preferences of the first occupants of the space. This is somewhat similar to installing water mains, gas lines, electric power lines along the streets of the city, and then building the houses on lots in such a way that they can be connected to the public utility systems. It would be uneconomical and exceedingly difficult to maintain adequate service in the future if the building utility supply mains were installed in the streets according to the needs of each individual house.

Types of Systems

Utility services are usually provided within a research laboratory building by either a horizontal or vertical distribution system or a combination of the two. Five systems are generally used to distribute laboratory utility services:

- The utility corridor system
- The multiple interior shaft system
- The multiple exterior shaft system
- The corridor ceiling with isolated vertical shafts
- The utility floor system

Utility Corridor System In the utility corridor design all service mains and ducts are brought to the various floor levels by means of a vertical central core which distributes the utilities by vertical mains, usually from a basement, sometimes from a roof mechanical room. The horizontal distribution of utilities from the central core may be at the ceiling and downward to individual casework or it can be directly along the floor through the wall in the pipe space behind the base cabinets.

This design provides access for maintenance and service personnel to the utility piping and duct work throughout the life of the structure. It has a high degree of flexibility for meeting the needs of changes in research program and has a high capability to meet a wide range of criteria with regard to environmental control and ventilation, temperature controls, lighting, electric power, etc. Its efficiency in terms of the net assignable area and the gross area is not high. It usually runs somewhere between 50 and 60 percent.

The utility corridor design is most applicable to multistory buildings—with a square rather than rectangular shape—and it should be used with reservation for laboratories with only one or two floors. This system results in functionally efficient laboratory buildings. It is extremely useful where future expansion, either horizontal or vertical, is planned and is particularly adaptable to those arrangements where offices with window exposure are separated from the interior laboratory units. In its simplest form the system provides for a single large room on each side of the utility corridor. The first refinement of this basic plan is the horse stall arrangement, which provides for partitions separating the various work areas but provides for no doorways or divisions from the circulation area around the perimeter. The refinement continues with the installation of walls and doors to separate the circulation perimeter from the laboratories.

1. Advantages

Excellent flexibility

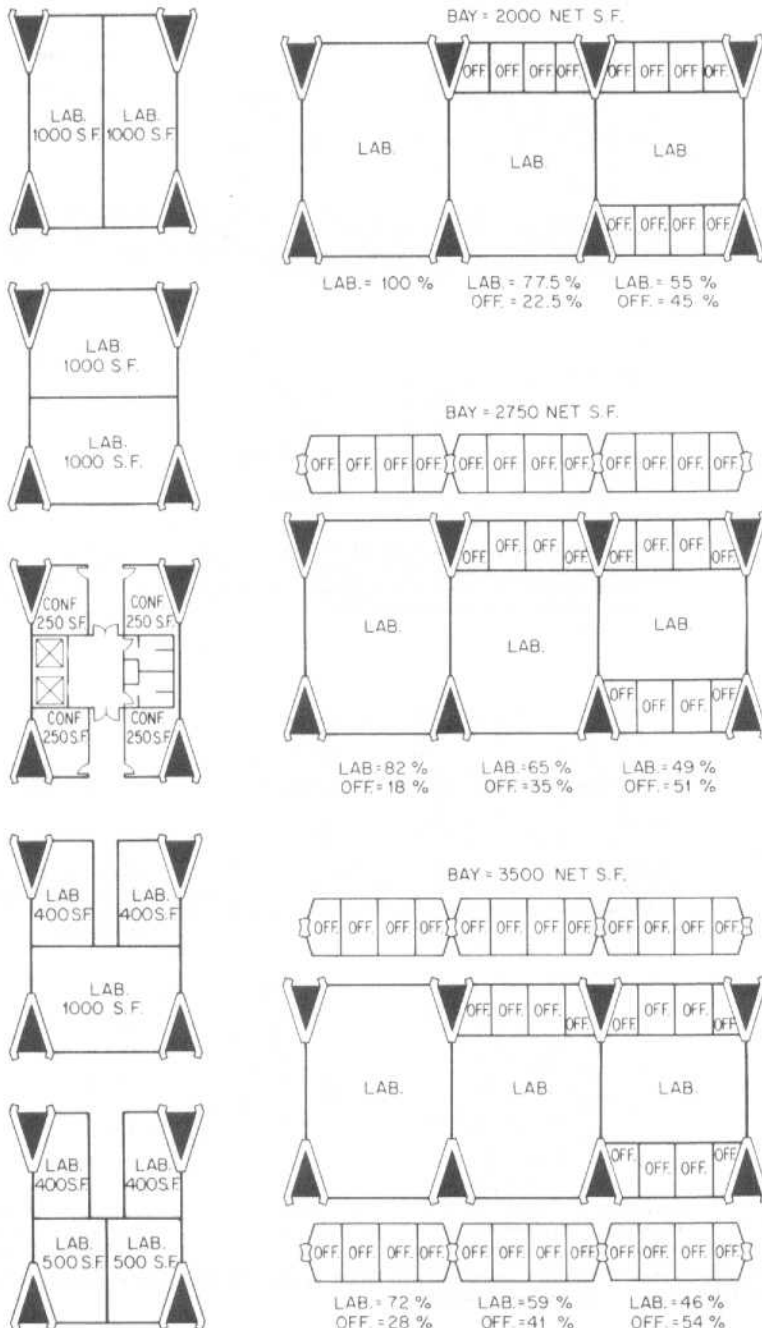

Fig. 3 A comparative study by Skidmore, Owings and Merrill of different ratios of office and laboratory space possible within a single, flexible system.

- Moderately high initial cost
- Low modification cost
- Low replacement cost
- Low cleaning (maintenance) cost
- Permits full utilization of walls
- Modifications do not interfere with conduct of work in adjacent modules
2. Disadvantages
 - Fair net to gross area efficiency which improves when units are located in parallel, thus saving one corridor
 - All rooms are "inside rooms"

Multiple Interior Shaft System This system provides for concealed utilities with duct work

and plumbing services in a series of regularly spaced shafts located either on both sides or on one side of a circulation corridor. All service mains and ducts are brought vertically to the various floor levels either upward or downward from the mechanical room. The shafts are located in each (or alternate) laboratory module or room on both sides of the central corridor. Distribution of utility services from the vertical shafts into the laboratory working areas is generally in the pipe space behind the laboratory benchwork. With the exception of the plumbing drains, in some designs the utility services are extended from the utility shaft below the ceiling in the laboratory and then

RESEARCH LABORATORIES

Feasibility: *Structural*: Compact plan may reduce cost. *Mechanical*: Although cores are separated, short mechanical runs reduce cost. *Circulation*: Double loaded corridors most economical. *Flexibility*: Changes may be made easily.

Feasibility: *Structural*: Economical arrangement. *Mechanical*: Very compact and economical. *Circulation*: Excessive corridors. *Flexibility*: Fair.

Feasibility: *Structural*: Compact plan. *Mechanical*: Separated cores and double runs of ducts, etc. may add to cost. *Circulation*: Doubling number of corridors is uneconomical. *Flexibility*: Rooms may be changed and added with ease.

Feasibility: *Structural*: Fairly economical. *Mechanical*: Very compact and economical. *Circulation*: Very economical corridor arrangement. *Flexibility*: Fair.

Feasibility: *Structural*: Compact plan may reduce cost. *Mechanical*: Compact system may reduce cost. *Circulation*: Double corridors uneconomical. *Flexibility*: Not as flexible as scheme above.

Feasibility: *Structural*: Economical arrangement. *Mechanical*: Very compact and economical. *Circulation*: Minimum length of corridors. *Flexibility*: Rooms changed and additions made easily.

Feasibility: *Structural*: Good form for economical structure. *Mechanical*: Very compact and economical. *Circulation*: Excessive corridors. *Flexibility*: Not too flexible.

Feasibility: *Structural*: Economical structure. *Mechanical*: Very compact and economical. *Circulation*: Excessive corridors. *Flexibility*: Not too flexible.

Fig. 4 Comparative study of different teaching laboratory layouts by Holmuth, Obata, and Kassabaum, with an evaluation of each in terms of economy and flexibility.

downward to the laboratory benches. The interior utility shaft system is not a good selection for buildings with only one or two stories; it is most efficient in multistory buildings and is frequently found in those with a long rectangular shape.

1. Advantages

- Good flexibility
- Moderate net to gross area efficiency
- Moderate initial cost
- Moderate modification cost
- Moderate replacement cost
- Easier to service than the exterior shaft system

2. Disadvantages

- More expensive and not as flexible as exposed systems
- Available space usually does not permit

individual supply and exhaust of fume hoods

Servicing interferes with traffic flow in corridors

The Multiple Exterior Shaft System This system brings service mains and ventilation duct work to the individual floor levels by a series of exterior wall vertical shafts located at each or alternate laboratory rooms or modules. Utility services are distributed from these exterior shafts into the laboratory rooms by means of the pipe space behind the base cabinets of the fixed equipment, or at the ceiling level. The multiple exterior utility shaft system generally should be considered only for multistory laboratories since its cost does not justify its use for one- or two-story buildings.

1. Advantages

- Good flexibility
- Moderate net to gross area efficiency
- Moderate initial cost
- Moderate modification cost
- Moderate replacement cost
- Low cleaning (maintenance) cost
- Permits full usage of walls
- Utilities are common with duct work and drainage systems
- Good appearance

2. Disadvantages

- More difficult to service or modify than other recommended systems
- Requires removal of one section of case work
- Modifications interfere with conduct of work in adjacent modules

More expensive and not as flexible as exposed systems

Available space usually does not permit individual supply and exhaust of fume hoods

The Corridor Ceiling Distribution In this system, utilities are located in the corridor ceiling and in some cases above the ceilings of the rooms on each side of the corridor and are supplied by one or two vertical pipe shafts. Distribution from the ceiling mains to the laboratory areas may be downward to the floor and upward through the floor above in order to supply two floors from one ceiling distribution arrangement. Generally, it is preferable to provide the distribution downward within each room to avoid perforation of the floor slab and consequent leaks and flooding due to accidents in later years.

This system is commonly used in research buildings with only one or two stories or where a single research floor is inserted in a multistory building primarily designed for other than research purposes. Designs employing exposed utilities are ideal for two-story or one-story-and-basement buildings where economy of construction is a major consideration.

1. Advantages

- Excellent flexibility
- Low first cost
- Low modification cost
- Low replacement cost
- High net to gross area efficiency
- Modifications do not interfere with conduct of work in adjacent modules

2. Disadvantages

- Requires increased ceiling height for same clearance
- Limits installation of wall cabinets
- Increased cleaning (maintenance) costs
- Requires independent type of air duct installation and drainage system
- Unsuitably

The Utility Floor Distribution System This system probably provides the maximum of flexibility and capability in research laboratory structures. Utilities, consisting of the duct work and the plumbing systems, are in separate floors. From the supply, the service mains and truck ventilation ducts are brought to each individual utility floor by means of a centrally located vertical shaft or tower. Then distribution is made laterally on each utility floor with final distribution made by penetrating the floor below or above to service the research laboratory areas. Although this system has almost unlimited flexibility, its cost is high and it has an extremely low net gross area of efficiency. This system is primarily suitable only to multistory buildings and is not a good selection for one or two stories.

1. Advantages

- Excellent flexibility to any portion of room
- Low modification cost
- Low replacement cost
- Modifications do not interfere with conduct of work in adjacent modules
- May be used with up-feed at every floor or may be combined with down-feed and located at every third floor

2. Disadvantages

- Very high first cost
- Low net to gross area efficiency

Plumbing Systems

A plumbing system for the health research laboratory should be suited to the type of utility distribution system selected.

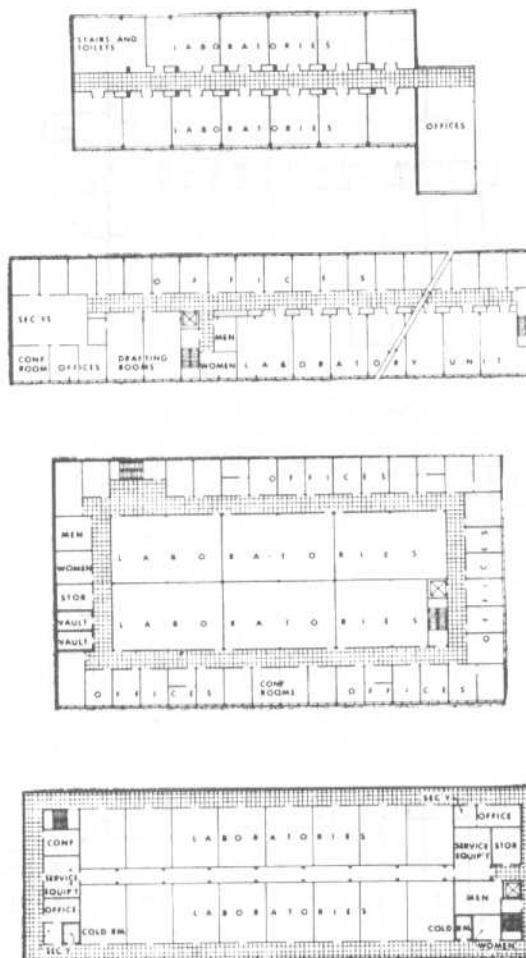

Fig. 5 Four plans by Walter Kidde Constructors, Inc. showing different basic methods of organizing an industrial laboratory.

Scope This discussion is limited to the piping systems within the laboratory building. Criteria for outside utility piping, water and sewage plants, and pumping stations are not included.

Flexibility and Capability Here again design incorporating long-term flexibility and capability is important. Focusing on the needs of individual laboratories or investigators leads to emphasis on the service piping or small services of various sinks and case work. Future revisions to such a system usually involve removal of the custom-provided service lines and either a relocation or resizing of the trunk mains in the building—a very expensive procedure.

The desirable approach is to determine plumbing service requirements either by floor or by large zones and to provide a trunk or a main distribution system that will reach all portions of the building. This should be supplemented by branch lines available to all rooms and spaces within the structure. Rooms and laboratory equipment can then be connected by small-size service piping to the nearest available branch drain bent or pressure service pipe.

As an example, plumbing stacks can be located to provide drainage capability within

10 ft of every square foot of the building, or plumbing vents and drains can be designed to provide drainage service within 20 ft of every square foot of the building.

Standardized laboratory services such as oxygen, vacuum, compressed air, hot and cold water, and gas should be designed so that the lines can be laid in parallel with a minimum of joints and elbows but appropriately equipped with valves to permit rearrangement of individual spaces without shutting off large areas of the building.

Code Requirements It is assumed that local governing codes will be followed. The following national codes may also be used for guidance: The American Insurance Association (formerly NBFU), The National Fire Protection Association, The American National Standards Association, The American Gas Association, The National Plumbing Code, and the American Water Works Association.

Functional Design Considerations

General The long-term capability and flexibility of the plumbing system requires special attention to the aspects discussed below. These considerations require that the piping follow a modular layout and, to a certain extent,

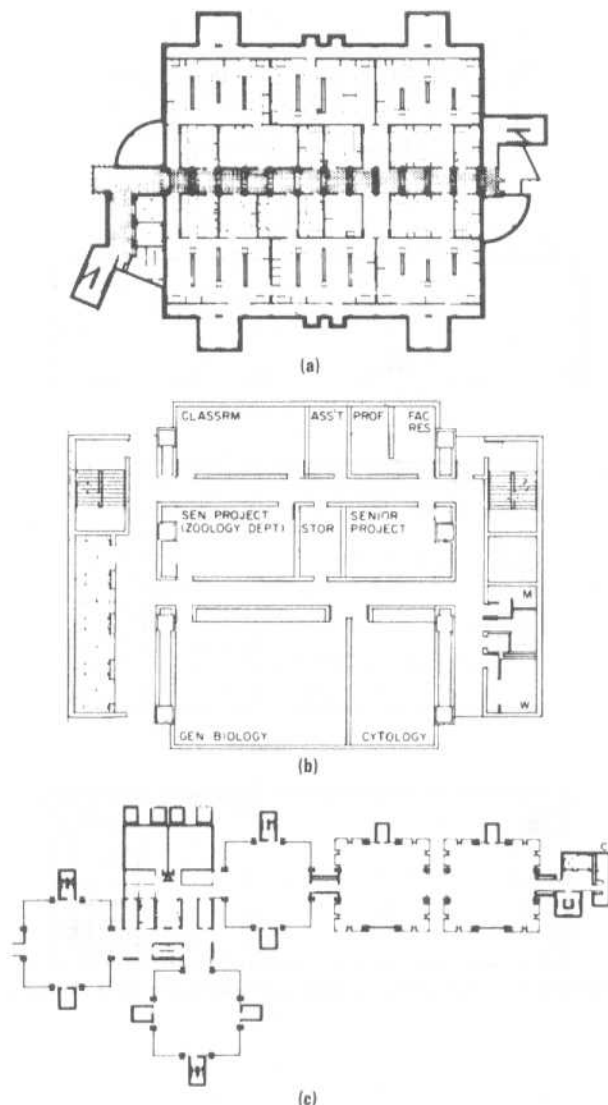

Fig. 6 Laboratory tower plans from (a) the Agronomy Building at Cornell University by Ulrich Franzen. (b) A projected science building at Barnard College by Vincent G. Kling. (c) Louis I. Kahn's Richards Laboratories.

limits the configuration and location of individual spaces as later defined by partitions.

1. Typical central services should be provided by means of vertical risers, horizontal mains, and individual room runouts, sizing the pipes in a manner which will permit, as far as possible, independent supply and control to various floors, zones, and/or individual rooms. This design approach should result in a repetitive and standardized (grid) arrangement of the risers, mains, and major branches.

2. Piped utilities should be accessible to permit extending the systems as required by future changes in research programs. Service pipe runouts (capped off when not used initially) at regular intervals in service shafts or cores will ensure maximum accessibility for future connections with a minimum of disruption to research programs in adjacent spaces.

3. To provide for future needs, the central service systems should include space for ducts and piping not initially required, pipe size which permits increased flows to meet larger demands, and adequate space to permit normal maintenance and repair.

4. Piping material should be selected on the basis of the properties required to maintain the quality of the flow material or to withstand corrosion or erosion by the various materials to be transported.

Horizontal Mains and Vertical Stacks Pipe mains and stacks may be run exposed or concealed in pipe chases or utility corridors. Pipe chases and utility corridors should have dimensions which will ensure properly spaced pipes and provide access for maintenance personnel. The chases and utility corridors will usually include air conditioning ducts and electrical conduits. The optimal arrangement of pipe spaces would provide utility mains adjacent to each health related space, so that the service to each laboratory would not be dependent on service to other spaces. The utility corridor located between rows of laboratory spaces would meet this criteria.

Pipe Runouts to Laboratory Space Satisfactory methods of installing runouts from vertical stacks and horizontal mains are overhead on exposed ceiling or behind laboratory case-

work and supported from the partition wall. Mains and risers located near nonlaboratory space should be provided with capped or plugged tees for ease of future connection.

Pipe Sizes in Mains and Risers The selected pipe sizes should include a factor for increased future use of the various gravity and pumped systems. For sanitary waste pipe, an anticipated increase of approximately 5 to 10 percent flow may be met by initially selecting the next larger size of pipe. Pumped services may meet future increased demand flows by an increase in pump head, while staying within acceptable pipe velocities.

Central Services Required Use of utility services will vary according to the department served. To provide greater flexibility, all laboratories should have air, vacuum, water, and gas services at all work areas.

Sanitary Piping System

Venting Each fixture should be back-vented into a circuit or loop vent in a manner prescribed by code. Locating plumbing fixtures in "peninsula" casework is not recommended, because of the difficulty in getting proper back-venting of the fixture.

Pipe Materials Ordinary galvanized iron or steel should not be used in waste pipe from laboratories intended for research in biology and chemistry, where concentrated acids may be accidentally or improperly discharged into the sanitary waste system. Acid-resisting piping materials should be used in all drainage systems serving laboratories in which acids will be used. A separate acid waste system may be necessary for areas of the building where large volumes of acids are used. This system should empty into a neutralization and dilution sump prior to discharge into the sewer.

Domestic Water Supply System

Sources of Water Supply Municipal or corporation supplies are usually preferred to other sources. A private supply of water is recommended only where public water is not available or it is impracticable to extend service to the site of the laboratory building.

Water Treatment A chemical analysis should always be obtained. Treatment of cold water supply is usually not necessary when the water is obtained from a municipality or from a utility corporation. Water softeners of the Zeolite type are recommended when the water has a temporary hardness of 10 or more grains per gallon, or a total hardness of 18 or more grains per gallon. Boiler feed water softeners are recommended if the temporary hardness is 4 or more grains per gallon.

Interior Water Piping

1. **Location of Mains** The water supply system should be distributed throughout the building and the mains should generally run near the ceiling of the lowest story.

2. **No Cross Connections** Cross connections between water supply piping and waste, drain vent, or sewer piping should be strictly prohibited, whether the connection is direct or indirect.

3. **Backflow Protection of Water Piping System** Water distribution systems must be protected against backflow [the flow of water or other liquids into the distributing pipes from any other source(s) other than its intended source]. Water supply connections or out-

RESEARCH LABORATORIES

lets to plumbing fixtures, tanks, receptacles, or equipment should be protected from backflow as follows:

a. The preferred method is by means of an approved air gap, as specified in American National Standard A40.4-1942.

b. Where it is not possible to provide a minimum air gap, the supply connection should be equipped with an accessibly located backflow preventer (nonpressure type vacuum breaker) installed beyond the last control valve in compliance with American National Standard A40.6-1943.

c. An alternate approved method is the use of an industrial water system to serve all laboratory work areas. This distribution system must be independent of the potable domestic system. This can be done by connecting the industrial water main to the building service line at the point of entry into the building, beyond the point of connection for the potable water and with a suitable backflow preventer inserted between the points of potable and industrial water system connections.

Distilled and Demineralized Water

Quality of Water The quality of the water required in health related spaces will determine whether distilled or demineralized water should be distributed through a central piped system. The analysis of local water characteristics will help determine if demineralization alone will produce water of the desired quality. Where demineralization alone will not suffice, distillation is required.

Size of System Stills and storage tanks should be large enough to assure an adequate daily volume of water. Still size can be determined on the basis of a continuous 24 hour operation of the still and the provision of adequate storage tank capacity. The system should be designed so that part of it can be shut down for servicing without cutting off the entire system.

Location of Stills Stills and demineralization equipment should be located at an elevation within the building sufficient to provide gravity flow to the outlets in the piping system. Mechanically pressurized systems are not recommended, since the pump and fittings may introduce impurities into the high quality water.

Materials of Construction "Block" tin (purity in excess of 99.9 percent tin) is recommended only when ultrapure water is required. Other materials which have been successfully used alone or as lining in tanks and piping are plastics, glass, aluminum, or stainless steel. The selection of a particular distribution piping and storage tank material must be based on water purity and contamination studies, previous experiences, and cost analysis.

Fire Protection

The requirements for standpipes and/or portable fire extinguishers are set forth in applicable local or national codes. Where the fire hazard in laboratories and ancillary spaces is above normal, an automatic sprinkler system or automatic detectors should be installed. Where the application of water by usual methods would be harmful or dangerous, an automatic or manual protective system should be installed, to suit the classification of fires from which protection is needed.

Gas Piping

Design All gas piping should be designed in accordance with NFPA Standard No. 54, Installation of Gas Appliances and Gas Piping. These lines should be sized to provide for expansion of the service and to maintain adequate pressure at the workbench. In general, gas piping should not be run in trenches, tunnels, furred ceilings, or other confined spaces where leaking gas might collect and cause an explosion.

Piping Materials Gas service pipe from the street to the building should conform to the regulations of the local gas company. Gas piping inside the building should be black steel with malleable-iron-banded fittings.

Valves Gas piping should have a shutoff valve just inside the building and at other points where it would be desirable to isolate certain sections.

Compressed Air and Vacuum Systems

Air Filters and Driers Compressed air must be of high quality—substantially free of oil, impurities, and water. Centrifugal compressors are ordinarily used to provide oil-free air. If a small amount of oil is acceptable at points of use, a main oil separator with additional separators at the using equipment will be adequate.

Air driers are required when moisture will create difficulty in laboratory instruments, or where compressed air piping may be exposed to freezing temperatures. Where laboratory requirements do not dictate dew points below 40°F, the dryness requirements can be achieved by the use of refrigerated water or direct expansion refrigeration in an aftercooler. The aftercooler may be air-cooled in the case of small compressors.

The pressure required at the workbench need not exceed 40 psig and flow requirements of 5 scfm at every station. The compressor pressure is based upon the needs of the equipment requiring the maximum pressure at point of use.

The vacuum requirements at the workbench are 5 cfm at 28 in. Hg at each service outlet. Receptor jars must be used between the equipment and the vacuum outlet, to prevent liquids and solids from entering the vacuum system. The air discharged from vacuum pumps should be exhausted outdoors, to prevent entry into the equipment room of toxic or flammable solvents.

Pipe material may be either copper or galvanized steel with threaded malleable-iron fittings.

HVAC Systems

Heating, ventilation, and air conditioning (HVAC) account for 25 percent to 50 percent of the cost of a health research facility. The design and functioning of the HVAC system should be considered very early in the planning process. Such early planning will avoid the extra expense and less satisfactory results obtained when HVAC engineering is limited to the inflexible confines of architectural design in progress.

The heating requirements of a health research facility do not differ significantly from those of a conventional commercial building, and have not been discussed here.

Electrical Supply

The power demand of laboratory instrumentation added to that of the building itself—for light, air conditioning, ventilating fans, etc.—makes the

provision of electric power, and its distribution, of key importance in the planning of a health research facility.

Flexibility and capability in this case means more than planning excess capacity for future needs. When electricity stops everything in the laboratory is affected. Emergency sources of power must be provided, and a system of priorities set up to determine which functions will have first call on the emergency power supplies.

LABORATORY PLANNING

Laboratory planning is generally regarded as one of the most difficult assignments with which an architect can be confronted. It involves the development of a layout to meet an exacting set of conditions, and the integration of complicated engineering services.

It is essential that the module and layout of the individual laboratories be considered in detail before even preliminary sketch plans are prepared. This can best be done in the following sequence.

Module

A module of 10 ft is recommended; this is the distance from center to center of two peninsular benches, and it is based on a bench width of 5 ft with a space of 5 ft between. In a one-module laboratory it is the distance between the center of one partition and the center of the next; it is based on a wall thickness of 4 in, a bench 2 ft 3 in wide on one side and a table 2 ft 6 in wide on the other—to give a space between of 4 ft 11 in. Generally an entirely satisfactory and clean-cut layout can be planned with the 10-ft module, but if it is necessary to have greater flexibility (i.e. rooms 15 and 25 ft wide), then a module of 5 ft must be used. Of course, the module is dependent on the width of the benches and the space between them. The most convenient metric equivalent is a 3-m module.

Width of Bench In chemistry laboratories, the generally accepted width of benches fitted with reagent shelves is 2 ft 6 in for wall benches and 5 ft for peninsular benches. In physics laboratories, widths of 3 ft and 6 ft are sometimes preferred, with a wide shelf for electronic equipment. In some laboratories, a bench width of 2 ft or 2 ft 3 in is adequate. Where solid timber tops are used, the consideration of width in relation to cost is relatively unimportant, but where sheets of some material are being used, the width should be considered in relation to sheet size so that waste is reduced to a minimum.

Space between Benches As building costs rise, it is to be expected that the distance between benches will receive closer scrutiny. Some research laboratory planners maintain that the increasing use of mobile equipment justifies the adoption of a 6-ft space. If it is adopted, then in a building 200 ft long it means the loss of one 2-module laboratory; conversely, a decrease from 5 ft to 4 ft 6 in means a gain of one 1-module laboratory.

The distance should be determined by considerations of convenience and safety, i.e., one person should be able to pass another (working at the bench) comfortably and without risk of collision

Reproduced from *Practical Laboratory Planning*, by W. R. Ferguson (1973), by Permission of Applied Science Publishers, London, England.

RESEARCH LABORATORIES

if the latter should step back unexpectedly. Experience has shown that 4 ft 6 in to 5 ft is ideal; 4 ft is cramped. It must be admitted that there are laboratories in which one man works between benches separated by as little as 3 ft 3 in, but such a small space should certainly not be thought of when planning a new laboratory.

In student and routine laboratories where there is less bench space per person and often two people will be working back to back immediately opposite each other, the space between the benches should be greater than 5 ft so that there is room for others to walk down the center.

Layout of Laboratory

Having established the module, it is now necessary to settle the size and position of laboratory offices, the depth of laboratories and the position of service laboratories, fume cupboards, and service ducts. All of these are vitally important in themselves, and of course they actually determine the type of layout which is to be adopted. Let us consider each of these items.

Laboratory Offices There are many scientists still alive today who have worked in laboratories where offices were not provided; the lucky ones had tables in the laboratory and the others just shifted some equipment off the bench to make space for report writing. For a number of years now, it has been standard practice to provide every scientist with an office; it is quite usual to provide individual offices for senior technical officers also, whilst laboratory assistants are expected to share offices or have writing spaces provided for them in the laboratories.

The best location for laboratory offices is always a controversial subject. Are they to be within the laboratory, adjoining the laboratory, on the opposite side of the corridor, or grouped in a separate part of the building? Is it essential for all offices to be on an external wall?

Some senior scientists consider an 8-ft by 6-ft office within the laboratory entirely satisfactory. These people spend most of their time actually working in the laboratory and the closeness outweighs the advantages of greater privacy and silence in a larger office across the corridor. In any case, for report writing it is much more satisfactory to use a carrell in the library. The internal office shown in Fig. 1 has a 6-ft by 2-ft 6-in table with bookshelves above and a filing cabinet beneath. This layout has the advantage that the full length of the building is available for laboratories and, with an off-center corridor, the service laboratories can be conveniently located along the opposite side.

Offices which adjoin laboratories also have the advantage of closeness and they can be larger than the internal office—one dimension is fixed by the module of 10 ft—but they do have the disadvantage that they use the more expensive serviced area. The alternative is to provide offices along the unserviced area on the opposite side of the corridor, but many scientists consider this separation from the laboratory undesirable, and the further the offices are from the laboratories, the more serious this becomes. In the case of offices grouped on another floor, the scientist may even think twice before making the effort to get to his laboratory.

Some scientists consider 10 ft by 10 ft an absolute minimum for an office, and others argue strongly for 10 ft by 12 ft, or even 10 ft by 14 ft. Certainly, when the offices are along one side of a corridor, a depth of 14 ft makes it possible

to get a more satisfactory layout for stairs, toilets, etc.

For large projects, it is necessary to consider laboratories on both sides of the corridor; in this case, offices must be either in (or adjoining) laboratories or grouped in a separate wing of the building. For still larger schemes, the double-width layout provides the best solution.

Details of the various positions of offices are shown in Figs. 2, 3, 4, and 5.

Depth of Laboratories Over the last 40 years, the depth of laboratories has increased from about 16 ft to 24 or 25 ft, with some going to 27 and even 30 ft. This has resulted in a better utilization of space and, as the span is within economic limits, the additional area is obtained

at a lower cost per square foot. For the standard type of peninsular bench layout, a clear depth of 24 ft is recommended.

Service Laboratories These laboratories are either planned to be integral with the laboratory and laboratory office unit or they are provided on the opposite side of the corridor; again, the various positions are shown in Figs. 2, 3, 4, and 5. Much of the equipment housed in these rooms is expensive and therefore it must be shared; it follows that this equipment must be located so that it is convenient to the maximum number of staff.

Fume Cupboards The risk of accident is greater in a fume cupboard [hood] than elsewhere in the

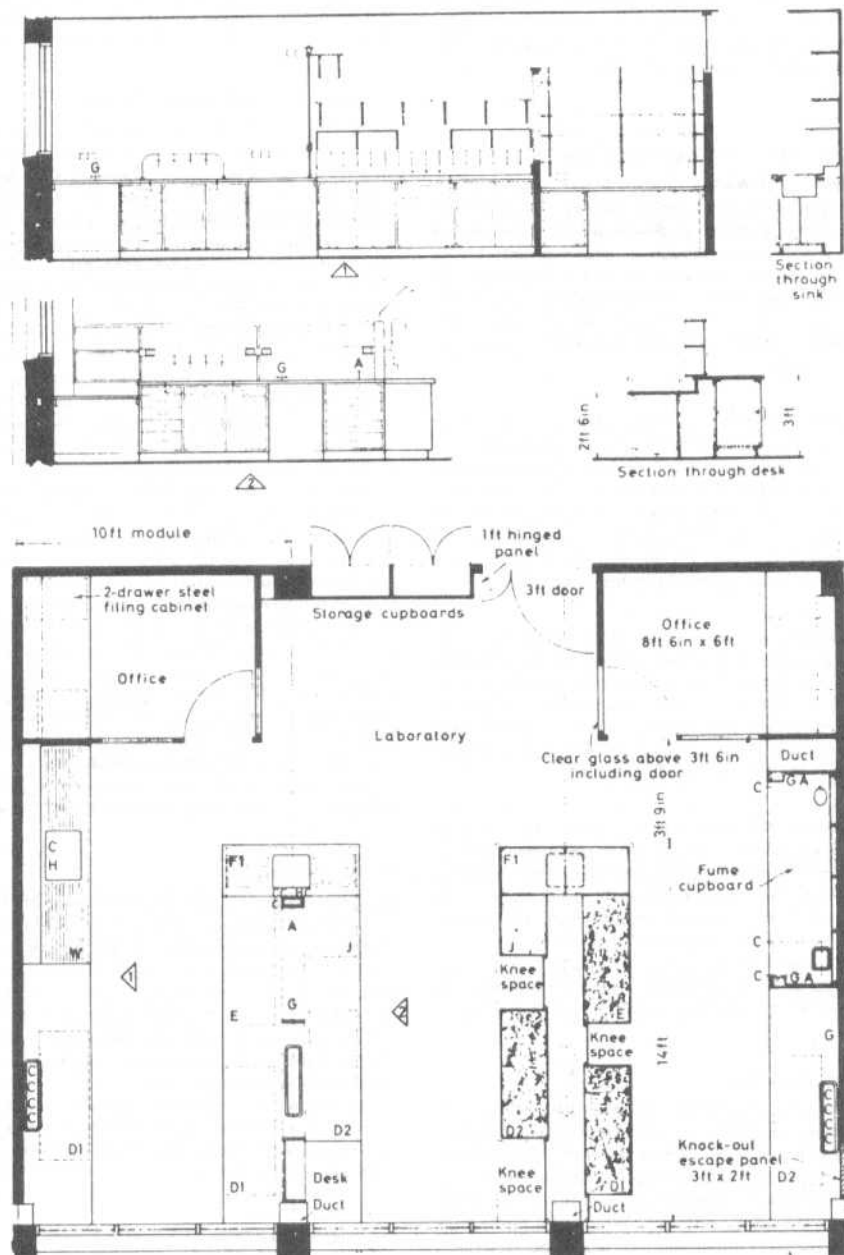

Fig. 1 Layout of a three-module, 30-ft by 24-ft laboratory.

RESEARCH LABORATORIES

laboratory; so, for reasons of safety, one should not be located where it will block an exit. Of course, if there is an alternative exit from the laboratory, this difficulty does not arise.

Fume cupboards require an exhaust duct with a diameter of from 8 to 12 in. Preferably the duct should connect from the top center of the cupboard and rise vertically to discharge the fumes above the roof. This does not present a problem in a single-story building—except, perhaps, when the architect insists on some symmetry in the positions of the outlets on the roof. However, in a three-story building, the position of the fume cupboards and the space required for exhaust ducts become more involved; if, in the preliminary planning stage, time is spent working out these details, it will obviate later troubles such as horizontal ducts which are too long or riser shafts which are too small.

The installation can be simplified by having the laboratories requiring the most fume cupboards on the top floor; quite often the entire ground-floor space can be allotted for rooms and laboratories without any fume cupboards.

Service Ducts The mechanical services are a major feature of any laboratory and, in order to achieve good design, location, and accessibility, they must be given a lot of thought. In some laboratories the installation will involve three or four pipes, and in others there might be six or more.

For benches serviced from the external wall, there should be horizontal and vertical ducts with removable covers. For benches serviced from the corridor wall, it is necessary to have a vertical duct accessible from the corridor. In some laboratories—especially if island benches are being used—the service pipes are reticulated in the space between the floor slab and the removable ceiling. This system does have the disadvantage that it requires many holes through the floor and, in the event of floods, these will cause trouble in the room below; also, repairs and alterations seriously disrupt work in the laboratory and, what is worse, it is somebody else's laboratory! Nevertheless, this system is preferable to the use of ducts in the floor because, even at high cost, it is quite difficult to get a cover which is removable, serviceable, rigid, neat in appearance, and perfectly flush.

For large projects where the double-width layout has been adopted, a service corridor is the obvious solution because it provides excellent accessibility to horizontal and vertical pipes and, in addition, space for fume cupboard exhaust ducts and miscellaneous laboratory equipment such as pumps.

Type of Bench There are three types of bench—peninsular, island, and wall. As the names imply, the peninsular bench projects from the wall and the island bench is free-standing.

With the greater depth of laboratories, the use of peninsular benches at right angles to the windows has become almost mandatory. They are preferable to island benches because the installation of services is easier and less costly, and there is minimum shadow when they are fitted with reagent shelves. Most laboratory workers will no longer argue that the extra space required to give access to four sides of an island bench is justified.

As a general rule, wall benches under windows should be avoided; facing the sun in front of windows on the east and west elevations makes working conditions quite intolerable. For windows

facing north, screening the low-angle sun in the winter is not always satisfactory; even with south-facing windows, glare can be a problem. Wall benches between peninsular benches create inaccessible pockets on either side and, for this reason also, they are not recommended.

Whether it be a one-, two-, or three-module laboratory, the combination of peninsular and wall bench at right angles to the external wall produces the simplest layout. The one-module laboratory provides the most wall space per unit area; the three-module laboratory has the widest application because in many cases it accommodates the optimum number of staff to share equipment and facilities.

Details of a layout which has been used quite extensively are shown in Fig. 1. This layout can be adapted to meet a wide range of conditions—for example, one or both of the offices can be omitted, the number and type of bench units and service outlets can be varied, the reagent shelves can be reduced in length or omitted, or one whole bench can be omitted to leave space for equipment or a rig for setting up apparatus.

Laboratory	Width of corridors	Length of building	Doors
Abbott	6 ft	224 ft	Single, 3 ft wide, opening out, serving rooms one side only
Battelle	7 ft 6 in	276 ft	Single, 3 ft 3 in wide, opening out
Bethlehem	7 ft	315 ft	Double, 2 ft 10 in + 1 ft wide, opening out from laboratory wall of service shaft at which point the corridor is 12 ft wide
Hoechst	6 ft 6 in	328 ft	Single, 3 ft 3 in wide, opening out from laboratory wall of service shaft at which point the corridor is 9 ft 9 in wide
National Bureau of Standards	7 ft	385 ft	Double, 3 ft + 1 ft 6 in wide, opening out from laboratory wall of service shaft at which point the corridor is 12 ft wide

Prototype Laboratory or Bench For large projects, it is a very good idea to have a prototype laboratory, and for small schemes at least a prototype bench. If these are to achieve their real purpose, they should be complete with services and accurate to the smallest detail. Most scientists can read plans very well; however, there are always some who can't visualize the finished product, and for them, and for the builder and his subcontractors, a prototype is a great help. Invariably, after examination and discussion, some improvements or economies are effected. Also, when a prototype is available for inspection by tenderers, its cost can be offset by more accurate estimating.

Windowless Laboratories and Offices Given a choice, most people would prefer to work in a laboratory which has windows; it is very pleasant to be able to look out on a garden or landscape, or even to get a glimpse of the sky. There is a prejudice against working in rooms without windows because it is thought that they create a sensation of being confined. The objection to this feeling of lack of contact with the outside world can be partially overcome if it is possible to 'look out if you want to'—for example, in some double-width laboratories, the door to the internal laboratory is opposite the door of the external office, and both are in line with the window; the doors have clear-glass top panels. In one windowless

laboratory I have visited, I was interested to see a brightly colored landscape hanging on the wall of an internal office; in another—a physics laboratory—many of the staff have worked quite happily for years in basement rooms; in yet another which has windowless laboratories and offices, the Director told me that, after 12 years' occupation, 'early apprehension that a closed-in feeling due to lack of outside windows would be a problem has not materialized.'

Laboratories without windows are shielded from the sun and external temperature variations, and it is possible to get much more accurate temperature control; another asset is more wall space. My impression is that windowless laboratories (and, to a lesser extent, windowless offices) are likely to be accepted more readily in the future.

Width of Corridors Factors which determine the width of corridors include the amount of traffic, the length of the building, and whether the doors open in or out; in overseas laboratories it is usual for doors to open into the corridors. Relevant details regarding five laboratories are:

There is very little traffic in the corridors of research laboratories, and in Australia, where the doors generally open into the laboratories, a width of 5 ft 6 in is adequate; furthermore, the narrower width helps to prevent the motley collection of refrigerators and cupboards which so often are lined up along one or both sides of the corridor. Nevertheless, 5 ft 6 in is an absolute minimum and assumes that there are no projecting columns; if the length of the building exceeds 200 ft, this width should be increased slightly to be visually acceptable.

Adoption of a Basic Laboratory Layout Every effort should be made to develop a basic layout which is standard throughout the building. This is not easy because on every job there is generally at least one scientist who, without any real justification, insists that his office or bench should be in a different position, and he will advance reasons why his idea of layout is necessary for some particular investigation. If he wins his argument and his laboratory layout is nonstandard, it so often happens that the project stops, or he leaves, and it is almost certain that his successor will require a different layout. On the other hand, there are some situations where it really is necessary to meet particular requirements, but these can and should be met by variations within the basic layout.

The establishment of a basic layout requires some firm decisions by the officer in charge, and these must be applied with a certain amount of ruthlessness if this proves necessary.

RESEARCH LABORATORIES

Fig. 2 Off-center corridor layouts, showing the relative positions of laboratories, service laboratories, and offices.

Layout of Building

Whilst the planning of each laboratory building has its individual problems, the range of layouts can be narrowed to a few which have been found satisfactory. Depending on the size of the project, the type of work, and the space available, any one of the following can be recommended.

Off-Center Corridor This layout has wide application for relatively small schemes—for instance, from a single-story building 100 ft long to several two- or three-story buildings about 200 ft in length. It has the great advantage that all the laboratories can have a south-facing aspect, and the two room depths provide flexibility in planning. Four variations of this layout are shown in Fig. 2.

Central Corridor This layout is more suitable for larger schemes. It has the advantage that the grouping of laboratories is more compact because they are on both sides of the corridor. Also, as the same width corridor is serving a wider building than in the case of the off-center layout, it provides a greater assignable space. However, it does mean that half the laboratories have a north-

facing aspect. Two variations of this layout are shown in Fig. 3.

Double Corridor This layout provides a good interrelationship between laboratory, laboratory office, and service laboratory, and it sometimes offers the best solution when the width of the building is fixed within certain limits. It has the advantage that, as the service laboratories are windowless, it is easier to obtain accurate temperature control; in many cases, the absence of natural light is an asset. (See Fig. 4.)

Service Corridor The double-width layout shown in Fig. 5 is especially suitable for large schemes. As laboratory services become more complex, and temperature control more critical, it is likely that this type of layout will be more widely accepted. The increased area at one level contributes to more efficient operation because the scientific staff are brought closer together and the sharing of equipment is facilitated.

Assignable Area The gross area is the overall area of the building, the assignable area is the actual area of usable space, and the difference is the combined area of entrance halls, corridors, stairs, toilets, ducts, and wall thicknesses. The 'use factor' is the ratio of assignable area to gross area, and it ranges from approximately 50 to 70 percent.

The best utilization of space is obtained by having one corridor serving rooms on both sides. For example, in the simplest type of three-story building with minimum entrance hall, a 5-ft 6-in corridor with 24-ft deep laboratories along one side and 14-ft deep service laboratories along the other:

Gross area	201 × 47		9447 ft ²
Assignable area			
Laboratories	196 × 24	4704	6762 ft ²
Service laboratories (allowing five modules for stairs, toilets, elevators, and ducts)	147 × 14	2058	
Use factor = $\frac{6762}{9447}$			71 %

Fig. 3 Central corridor layouts, showing the relative positions of laboratories, service laboratories, and offices.

Obviously, a corridor serving rooms on one side only, or two corridors serving three rooms, decreases the ratio of assignable to gross area and therefore increases the cost.

Floor Space per Person The space required by scientists varies greatly. Most require a laboratory, a laboratory office, and access to several service laboratories, but quite a number need additional facilities such as glass-houses, animal pens, or large areas for pilot-plant investigations or the preparation and storage of many hundreds of specimens. Then again, some scientists use equipment which is small and commercially available, whilst others must have large equipment which often has to be specially designed and fabricated in workshops on the site.

Bench Space per Person One measure of good laboratory accommodation is adequate bench space. The layout shown in Fig. 1 provides 62 lineal feet of bench; this represents 15 lineal feet per person for four (with a maximum of five) persons. A bench length of 12 to 15 ft per person is a generally accepted standard, and an uninterrupted length is preferable to several short lengths.

Fig. 4 Double-corridor layout, showing relative positions of laboratories, service laboratories, and offices.

Fig. 5 Double-width layout with service corridor, showing relative positions of laboratories, service laboratories, and offices.

WAREHOUSING AND STORAGE

Warehousing Warehousing is the receiving, storage, and delivery of goods.

Receiving Receiving is the acceptance of goods with a degree of accountability therefor.

Storage Storage is the safekeeping of goods in a warehouse or other depository.

Delivery Delivery is the transfer of goods to transportation carrier or customer.

Distribution Distribution is a function of warehousing which includes the preparation and delivery of goods according to plan or special order.

General History

Modern warehousing has progressed in recent years to a point where old warehouse structures are costly to operate. The old-type warehouse buildings usually do not have sufficient floor-load capacity in the upper floors and do not allow the adoption of economical storage methods in the receiving and shipping areas. The emphasis today is on the maximum use of the "cube" rather than the square foot of warehouse space, on distribution rather than storage, and on power handling equipment rather than hand labor.

The design of a warehouse should be based upon the most economical methods of materials handling. High stacking, with minimum use of aisles, is the keynote of maximum "cube" utilization. Modern warehouse design generally includes clear spans ranging from 60 to 100 ft, roof elevation sufficient to allow 18 to 20 ft (and higher) stacking height, and shipping and receiving areas located at box car or truck level.

Fundamentals of Modern Warehousing

One-Story-Type Building (Fig. 1) The study of multistory vs. one-story warehouses is complex and requires a complete engineering survey. The factors for consideration are partially listed herewith.

One Story:

1. Low-cost ground advisable
2. Availability of land for expansion
3. Less time for erection
4. Less area lost—sidewalls, columns, elevators, stairways, etc.
5. Adaptability to long-span construction
6. High floor loads
7. Greater flexibility for layout changes
8. Greater handling efficiency possible
9. Supervision easy and effective
10. Maximum use of daylight and natural ventilation
11. Hazardous areas easily isolated

Two (or More) Stories:

1. High cost of ground
2. Limited area for site
3. Natural topography may permit entrance at different levels
4. Ease of expansion if foreseen
5. Floor load may be limited in upper levels
6. Product stored and handling equipment should be light in weight or small in bulk
7. Handling distances reduced with gravity flow
8. In some locations, less dirt and better ventilation on upper floors
9. Lower heat loss through roof

In general, the overall economic evaluation of the one-story warehouse indicates a lower investment per cubic foot of storage space. The low-cost types of roof construction and the reduction of steel and masonry for additional floors are the significant cost-reduction items. Another major point of concern is the demand for increased floor-load capacities to support industrial truck equipment and heavier unit loads.

Flexibility of Layout and Equipment Flexibility of storage allocations is obtained by the installation of minimum permanent storage aids. This can be accomplished by providing bolted-up types of pallet racks, bins, or shelves. The use of pallets and pallet pattern selection guides should provide the maximum cube utilization as well as stability. The large-size pallets are usually economical for warehousing operations.

Shipping and receiving areas should be designed for two-way operation over the same platform where possible. The main aisles of transportation within the warehouse should allow the passage of materials handling equipment in both directions.

Efficient material movement is best obtained by wheeled vehicles in a warehouse of peak demands. Goods can be stored or accumulated prior to shipping during off-peak periods.

The versatility of the fork truck and package conveyor is responsible for their wide acceptance. Fork trucks are made especially adaptable with a variety of attachments for special purpose handling.

Selection of Warehouse Materials Handling Equipment The proper selection and use of materials handling equipment is an important factor to initiate and maintain warehouse operation efficiency. Warehouse design is often evolved around a well-engineered handling technique.

Typical handling methods include the following:

1. Tow conveyor (dragline conveyor)
2. Pallet systems (skids, bins, racks, unit loads, etc.)
3. Tractor trailer and fork truck (wheeled vehicles)
4. Overhead systems (monorail, bridge crane, stacker crane, etc.)
5. Conveyors (vertical and horizontal movement)

Considerable emphasis has been placed on narrow-aisle handling during recent years. The

narrow-aisle straddle fork truck with 100 percent selectivity of goods in stock on pallet racks has been much used. Space savings have been particularly attractive with small pallets where right-angle stacking aisles have been reduced in some cases to 6 ft. The aisle-space savings of the straddle fork truck are usually offset by increased operating cost due to the slow speeds in stacking and transporting inherent in the equipment. Increased side clearance between pallet stacks and the decreased stability of the truck chassis for high stacking heights are also items to be considered for overall evaluation.

When selectivity is not a prerequisite and bulk storage is possible, the straddle-type truck is less desirable on account of the clearance required between storage rows. A later design of the narrow-aisle type industrial truck provides forks which retract the pallet load within the wheelbase of the vehicle. Normal pallet side clearances can be maintained comparable to the standard fork truck. The front-wheel diameter has been increased to reduce floor wear experienced with the straddle fork truck with small steel wheels. The limitations of narrow-aisle equipment as listed above should not be overlooked in any warehouse operation where high turnover of inventory is required.

Tow conveyor systems have been installed in many warehouses and truck terminals where order makeup or sorting operations require maximum flexibility.

Tractor-trailer trains have been utilized to advantage where long horizontal movements are required. With a fork truck loading pallets on trailers and a second fork truck unloading pallets at the delivery point, maximum utilization of equipment is obtained. In this way, heavy tonnage can be handled in minimum time, or a tractor-train schedule can be set up for repetitive delivery to various points.

Overhead bridge cranes require no aisle space if the goods to be stored are handled with special lifting devices. Paper rolls and other large units are warehoused in this manner. Monorail systems are used as a general purpose method of handling bulky, extra long, or heavy loads in congested areas.

The stacker crane is recommended for evaluation when selectivity of pallets or unit loads is required in narrow-aisle operation. Maximum storage heights may be attained in safety for maximum vertical-height utilization. The hoisting mechanism is suspended from the overhead traveling bridge. Recent comparisons in warehouse floor-space requirements indicate that the stacker crane is more efficient than the straddle fork truck.

Fixed-route package conveyors are usually designed to handle a constant flow of material of similar products. Cases, boxes, drums, bags, etc., can be conveyed from production line, through warehouse, to shipping platform with minimum handling. Conveyors are usually engineered for a specific size and weight of product. A thorough study is required to select the most suitable and economical handling system.

William Staniar, M.E., Editor-in-Chief, *Plant Engineering Handbook*, 2d ed., McGraw-Hill Book Company, New York, 1959.

Utilizing centrally located short-lot and bin-storage operation, coordinated by use of dragline conveyors

This bin layout emphasizes a direct-flow replenishment and stock selection operation

Fig. 1 Typical large warehouse layout.

Effective Warehouse and Storage Layout

The overall receiving, storage, and shipping costs can be classified generally as follows:

1. Occupancy or fixed overhead charges
2. Labor or handling expense

The principles of space utilization can be described as operating in three dimensions. The percent effectiveness (volumetric efficiency) may be calculated from the following:

$$\begin{aligned} \text{Space utilization (\%)} &= \text{area utilization} \\ &\quad \times \text{vertical-height utilization} \\ &= \frac{\text{net storage area}}{\text{gross storage area}} \\ &\quad \times \frac{\text{height utilized}}{\text{usable vertical height}} \times 100 \end{aligned}$$

Area utilization (Fig. 2) requires the proper analysis of alternate materials handling methods. Emphasis is placed on the study of the floor plan to provide a maximum ratio of net usable area to gross floor area. The net storage area is the floor space actually occupied by goods. The gross storage area is the usable area plus adequate operating aisles for handling facilities and traffic needs.

Additional area is usually required for miscellaneous functions. Examples are listed herewith:

1. Space for empty pallets
2. Special packaging or makeup areas
3. Irregularities due to columns, odd corners, etc.
4. Space for offices, equipment, etc.
5. Shipping and receiving areas
6. Odd lots and balances

Vertical-height utilization usually necessitates packaging evaluations plus the consideration of safety and special equipment. The maximum stack height allowable is limited by the crushing strength of the bottom package. Non-

Fig. 2 Space utilization - a three-dimension operation.

stackable or fragile loads are tiered one above the other with the use of pallet racks or other storage aids. Usable vertical height (in space utilization formula) is the distance from floor to underside of sprinkler system nozzles. Fire underwriters allow a 10 percent reduction in rates when a minimum of 18 in. is left clear under the sprinkler heads (Fig. 3).

The occupancy cost of warehouse buildings includes the investment of the structure itself with corresponding fixed depreciation and maintenance expense. A vertical stacking height of 18 to 20 ft is usually found to be most economical from a cubage cost estimate review. Avoid the false concept of economy of ground-level floor construction for new buildings which in many instances results in costly "in" and "out" handling in the shipping and receiving areas. Warehouses are designed as a

rule for floor-level operation for both rail cars and trucks:

1. Rail cars—3 ft 7 in. above top of rail
2. Trucks—4 ft 4 in. (average) above ground

Doors 8 to 12 ft wide and 10 ft high are usually ample for use with high-stacking equipment. Door spacings for box cars can be set at 45 ft for standard 40-ft rail equipment. Truck delivery doors should be set at 15 ft center to center. Buildings with long-span construction are desirable to eliminate waste space and provide increased flexibility for handling operations. Spans up to 100 ft are not uncommon with little or no extra construction cost.

Effective storage layout includes careful analysis of the following:

1. Activity of item warehoused (turnover)
2. Bulk and weight of package or unit load

Industrial WAREHOUSES

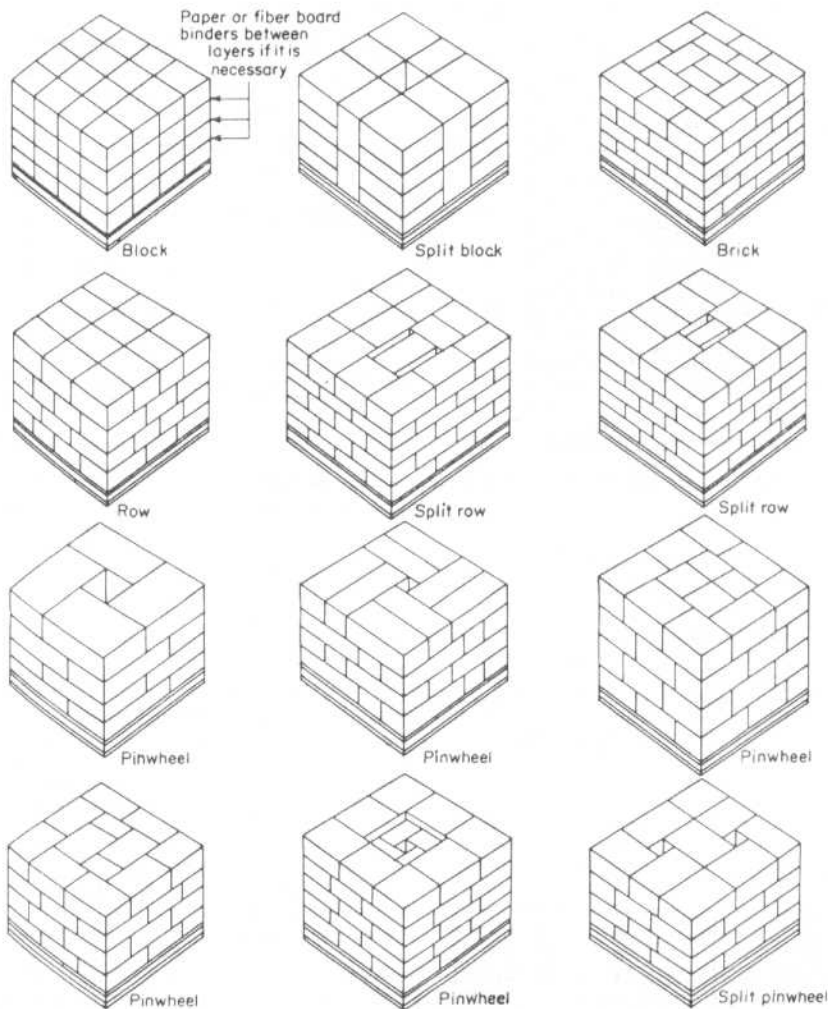

Fig. 3 Standard pallet patterns.

3. Number of items and quantity of each

4. Shape, value, hazard, or other special considerations

The application of the "ton-mile" principle can serve to reduce handling costs when a floor plan is designed for the storage of a large variety of items, lots, batches, etc. The items to be stored are located within the warehouse by popularity or special groupings. Logically the most popular items are stored closest to the shipping dock to reduce the length of travel of materials handling equipment or crews. Any storage system or layout which minimizes the movement of warehouse operations reduces the ton-miles or pound-feet of work performed.

The physical characteristics of a warehouse determine the capacity factors of storage layout, namely:

1. Floor-load capacity
2. Ceiling height and allowable stack height
3. Location of doors, loading facilities, elevators, firewalls, etc.
4. Column location, size, and spacing between centers
5. Location of aisles for operating space, access to stock, and protective equipment.

The cost of handling "in" and "out" of

storage is an operating expense which can never be recovered. The overall cost per unit weight or volume is thus the prime consideration of efficient warehousing and quite often is the only expense that can be reduced by improved materials handling methods.

Straight-Line Flow or Assembly-Line Principle Straight-line flow is inherently efficient and usually is adopted in warehouses adjacent to production areas. Conveyors and pallet systems illustrate typical methods of efficient handling.

Order pick lines in a grocery warehouse are characterized by the assembly-line principle.

Shipping and Receiving Areas The receiving area of a warehouse should be located adjacent to incoming rail or truck facilities and as convenient as possible to the storage area. The receiving dock is usually separated from the shipping area if possible to minimize cross traffic and possible confusion. The number of unloading positions required is dependent upon the volume of receipts or the maximum number of cars or trucks spotted at the same time. The light weight of portable aluminum or magnesium dockboards is desirable when power equipment is not available for positioning units of conventional steel construction.

Weather protection at the unloading positions permits continuous handling operations. Loading platforms located outside the warehouse building can be designed for one-way or two-way traffic where required.

The proper control, checking, and sorting of inbound materials is important for the prompt and efficient delivery of outbound shipments. The size of the receiving area is determined by the analysis of the temporary storage lag needed to perform the necessary inbound handling and inventory control operations.

A shipping area (or dock) receives materials for outbound shipment after selection and transfer from storage. The preassembly of orders according to plan requires sufficient room to perform packing, packaging, or preparation operations prior to shipment.

The size of the shipping area is dependent on the makeup time of filling orders and the quantity of simultaneous loading operations during peak periods.

Calculation of Storage Space (Area Utilization)

Gross

warehouse area = inside total square footage of warehouse

Net

storage area = actual area occupied by inventory, not including aisles plus space for empty pallets plus shipping and receiving areas plus allowance for "honeycombing" plus special inventory (inspection, etc.)

Interference = irregularities due to columns, odd corners, etc.

Miscellaneous = space for offices, equipment, etc.

Gross

warehouse area = net storage area plus aisles plus interference plus miscellaneous

Rule of thumb (for general package warehousing):

$$\frac{\text{gross warehouse area}}{\text{net storage area}} = \frac{3}{2}$$

or Net storage area + (50% net storage area) = gross warehouse area

This rule is accurate for average warehouses, but actual analysis of the layout is recommended.

"Honeycombing" is a warehouse term used when space is not fully occupied because of partial withdrawal of inventory. Maximum honeycombing factors are in the range of 75 to 90 percent of maximum capacity, depending upon the activity, number, and quantity of items stored.

WAREHOUSES—WATERFRONT

Warehouses will vary considerably in different ports because of various types of cargo handled, climate, local stevedore practices, economics of various building materials, types of land transportation serving the facility, etc. The warehouse to be discussed herein is one used for the long-time storage of goods as opposed to transit sheds that receive, handle, and discharge sundry cargoes "in transit." For purposes of this study, only warehouses connected with maritime commerce, handling cargoes to and from ships will be considered.

This means a building constructed in the general vicinity of a ship berth where cargo to be shipped out or which has come in by ship can be assembled and which requires comparatively long-time storage.

For reasons of economy of operation, the distance from the operating berth should be kept to a minimum to cut down travel time for stevedore equipment and provide for the rapid loading or unloading of the ship. This distance, however, should not be so close to an operating berth that the warehouse could be used as a transit shed, thus changing its true function. Generally speaking, this would mean that a warehouse should not be closer to an operating berth than the length of the berth. Cargoes scheduled for long-time storage could then be economically transported to the warehouse.

General Dimensions

The over-all dimensions of a warehouse are quite often limited by the available space. However, where space restrictions do not occur, the size can be best established by the use to which the warehouse is to be put.

Warehouses to be used in conjunction with transit sheds should be comparable in size. This means a warehouse with a gross area of 70,000 to 90,000 square feet. The width and length can then be determined from the dimensions of the site and the space required for access roads and railroad sidings.

To maintain good fire protection, the building should be divided into compartments separated by fire walls equipped with fire doors. The type of cargo to be stored will sometimes regulate the allowable area in these compartments and also the vertical clearance under the structural framework. At least 2 ft must be provided between cargo stacks and automatic sprinklers. A clear height of 22 to 24 ft would be ample to allow for automatic sprinklers and pendant electric lights.

Service Facilities

Where space permits, it is particularly desirable to provide loading platforms at truck bed eleva-

tion at each side of the warehouse, and also railroad tracks for direct transfer of goods from rail car to warehouse or vice versa.

To accommodate trucks that may wish to drive into warehouses where a center aisle is provided, it is necessary to construct ramps at the ends of the building connecting the depressed areas to the regular floor level. In this way, trucks can be unloaded inside the warehouse with lift trucks.

In localities where considerable rainfall occurs, it is very desirable to have protective canopies built out over the loading platforms.

Loading platforms should be wide enough to allow for easy maneuvering of mechanized equipment during loading and unloading operations.

Column Spacing

The advisability of interior columns in warehouses is a disputed question—warehousemen contend that columns interfere with the movement of cargo. There is no doubt that a wide spacing of columns is an advantage.

Whether one row of columns along the centerline is preferable to two rows at the third points is largely a matter of opinion. One row causes less interference to cargo handling and stacking, and allows two side aisles for trucks. On the other hand, two rows allow a center truck aisle which is adequate for most conditions. The width of the building will in many cases be the deciding factor in regard to selecting the most economical span for the roof system. Clear span construction is without doubt more desirable from an operating standpoint, but the additional cost may rule it out.

The spacing of the column bays is another controversial subject. The type of roof construction in many cases will determine the economical span for roof purlins and joists. Bay spacing of 20 to 40 ft appears to be common practice.

Foundations

Foundations are either pile supported or spread footings. Careful analysis of the soil by means of borings should be made previous to design unless previously obtained data on soil characteristics is available.

When soil conditions are questionable, load tests, test pile driving and pile load tests may be required.

Where soil conditions show adequate stability, spread footings can be used. Even where areas are freshly filled, it is often possible to obtain adequate compaction with the use of mechanical compactors. The degree of compaction must be carefully measured in the field by established tests.

Structural Frame

Steel Frames Structural steel shapes are quite often used for warehouse framing because of easy availability, economy, and simplicity.

A great many steel companies are now produc-

ing "prefab" buildings of lightweight steel shapes. They come in a variety of spans and bay spacing and offer a choice of truss, arch, or rigid frame. These buildings generally require interior columns, and if the spacing of columns is such as not to interfere with the functional use of the building, they offer an economical solution to certain specific warehouse requirements.

Timber Frames Wherever timber is readily available and competitive with steel or other materials, it may be more economical to construct a warehouse using heavy mill construction. This type of structure is considered a better fire risk than unprotected steel.

The use of glued laminated wood members is also becoming quite popular. They have the decided advantage of a reduction in shrinkage and provide greater strength for a given size member.

A recent development in the Southwest is the pole-frame type of construction. Basically, it is a building with its main columns made up of treated timber poles with simple wood trusses and wood roof beams. The roof is either built up over a wood deck or of corrugated steel or aluminum supported by wood purlins. Walls are usually wood framing with corrugated metal siding. Relatively close spacing of columns is required with this type of construction which results in reduced maneuvering space for mechanical equipment.

Reinforced Concrete There are many advantages to be obtained by using reinforced concrete wall construction, such as low maintenance cost, long life, ability to withstand rough treatment by heavy stevedore equipment and high resistance to fire. Tilt-up concrete wall construction has been used considerably in recent years to great advantage. In either case, these types of wall construction are usually combined with steel or wood trusses and conventional roof decks.

An all-concrete construction method can be obtained by the use of prestressed concrete beams and columns, and in recent years thin shell barrel arches of prestressed concrete have been successfully used.

Wall Framing and Sheathing When corrugated steel or aluminum wall sheathing or one of the various new patterns of rolled metal sheathing is used, it is generally secured to steel girts and studs for steel-framed buildings and wood girts and studs for timber construction. In either case the exact spacing of girts and studs is determined largely by local building codes, wind loads, column spacing, and the gage of the metal used.

Obviously the used of reinforced or tilt-up concrete walls eliminates the need for girts and studs and provides the necessary sheathing. Concrete walls, however, do add a greater weight to foundations and increase the building cost. Offsetting this is the more permanent construction obtained

WAREHOUSES—WATERFRONT

and the ability to withstand rough treatment from heavy cargo-handling equipment.

As a compromise between these two systems, some warehouses are constructed with a concrete wall built up to a height of 4 or 5 ft with the lighter wall construction using girts and corrugated metal extending up to the eaves or parapet. One disadvantage of corrugated siding is its susceptibility to damage. This can be partially remedied at a moderate increase in cost by applying solid sheathing, either 1-in shiplap or the cheaper grades of plywood, secured to the girt system. This method not only protects the metal siding, but it also provides additional strength to the building to resist wind forces, and has some insulating qualities which may be desirable.

The gage of the sheet-metal siding or roofing is important. Although the standard gages are more economical and easier to procure, there are other factors which may warrant the selection of heavier gages. In areas of high winds a heavier gage than standard would be desirable, and where warehouses are located near the waterfront and subject to frequent fog and damp air conditions, heavier gage metal would be a distinct advantage to offset corrosion.

Regardless of the gage selected, it is of prime importance to use galvanized sheets to resist corrosion. The standard 1 1/4-oz coating is generally used, but here again the longer life obtained by using 2-oz coating may justify the additional cost. Although many warehouses are left unpainted there seems to be a trend toward more attractive buildings utilizing bright colors or contrasting panels. Prefabricated panels of aluminum or porcelain-enamelled steel in various attractive colors are now available but the added cost has acted as a deterrent for most low-cost commercial projects unless offices are incorporated into the plan, in which case some distinctive design can be justified. Aluminum panels, doors, or windows used in locations that are exposed to industrial or sea-coast corrosive atmospheres should be of an alloy that will resist corrosion. Alloy 6063-T5 has been successfully used in these locations.

Roof Framing, Sheathing Corrugated aluminum or galvanized steel is frequently used for roof construction. It is generally supported on steel purlins that in turn rest on steel trusses. Where the spans are not excessive, wood joists supported on steel purlins can be used. One-half-inch-thick plywood diaphragm roof sheathing is laid over the joists and a built-up composition roof applied on top. This type of construction has the advantage of providing a good bracing system in the plane of the top chord, thus taking care of wind loads and other horizontal stresses.

Two-inch-thick T & G roof sheathing is sometimes used nailed to timbers resting on the steel purlins. This type of construction also has good diaphragm qualities and, being of mill type construction, has a good fire insurance rating.

There is an endless variety of built-up composition roofs available to choose from, but a substantial watertight roof is essential and consequently nothing less than a "20-year" bonded roof should be considered.

Poured-in-place concrete and lightweight concrete, poured-in-place gypsum, and vermiculite are other materials frequently used for roof construction. The initial cost and the additional weight that must be carried by the framing system and foundation are factors that should be considered in selecting these materials, and the advantages and disadvantages carefully analyzed in

relation to the overall anticipated life of the entire structure.

Floors

Floors are either portland cement concrete or asphaltic cement concrete. The final finish on portland cement concrete floors is important. Steel trowel finishes are inclined to be slippery, particularly if water or oil accumulates on the surface. A light broom finish is more desirable providing an adequate nonskid surface.

Asphaltic cement concrete makes a good wearing surface either when applied over a concrete slab or crushed-rock base. Various degrees of roughness can be obtained to provide sufficient traction for mechanized equipment. Although it is susceptible to disintegration due to oil and gasoline drippings, it is easily patched and there are various "sealers" that can be applied which alleviate this situation.

It is important that floors be given a sufficient slope to drain properly. Opinions vary as to how much this slope should be, but range between 1/8-in and 1/4-in per foot.

At doorways, in order to prevent rain from driving in under the doors, this slope is sometimes steepened for approximately 5 ft inside the opening. Lift trucks can negotiate this slight ramp smoothly. Another more positive method is to install a continuous drainage trough under each door equipped with a suitable grating set flush with the paved surface.

Appurtenances

Doors The finest type of door used on warehouses is the vertical rolling steel door, a door constructed of many interlocking steel slats all connected together and secured by guides on both sides of the opening. The door curtain slides vertically up the guides and is rolled up on a steel pipe barrel. The operating mechanism for this type of door is either an endless chain which turns a sprocket and train of gears connected to the pipe barrel, or by crank, bevel gears, and steel shafting. The weight of the steel curtain is counterbalanced by helical steel-spring tensioning devices. Large doors are generally motor operated, the open and closed positions being controlled by limit switches.

This type of door can also be used as a fire door, in which case the spring tension is adjusted to close the door automatically when a lever is tripped by the melting of a fusible link.

There are many "overhead" type doors on the market that are very competitive with the vertical rolling steel door. They may be metal or wood and have a large variety of operating procedures. The so-called "up and over" type is raised as a unit by means of cantilever arms and tension springs, similar to residential garage doors, and in the open position lies above and inside the door opening. A variation of this door is one in which the door folds in two leaves before assuming a horizontal position above the door opening, the advantage being that the projection into the building is reduced.

An overhead type of door composed of several horizontal sections hinged together that slides vertically in tracks at each side and above the door opening has become quite popular in recent warehouse construction. It can be constructed of wood or metal (quite often aluminum), and can be manually operated in comparatively large sizes, although it is adaptable to motor operation. In the open position, it too, lies above and inside the door opening.

All these previously described doors require a

moderate amount of headroom between the door head and ceiling or roof construction, and with the exception of the vertical rolling steel door, all can be equipped with windows to provide additional day lighting.

If the eave height of the warehouse is not less than one and one-half times the door height, two-section counterbalanced vertical-lift doors can be installed, either manual or motor operated. These doors are easily and quickly opened.

The conventional one- or two-unit horizontal sliding door, although virtually foolproof, is, nevertheless, unwieldy and requires large blank wall spaces to house it in the open position. For this reason it limits the number and location of doors to the detriment of the overall design.

The spacing of doors is largely determined by the type of cargo to be stored and the frequency of loading or unloading of the stored material. Warehouses constructed for a specific commodity can have the doors located to provide the minimum travel distance for loading or unloading operations. However, most warehouses adjacent to the waterfront would accommodate a variety of cargo. It would be better to have an excess of doors rather than an insufficient number, as cargo can always be stacked in front of a closed door. It is important, however, to have doors on each side of the building opposite each other, and also to have doors on the ends so that trucks can enter or leave by means of a center aisle. Symmetrical spacing of doors allows for an efficient traffic pattern throughout the building.

The selection of door sizes should be determined by the size and type of equipment and cargo that will be used. Lift trucks, straddle carriers, and even individual cargo packages are getting larger and larger, and for safe operation require wide doorways. Doors 16 ft wide and 16 ft high are commonly used, and even doors 18 or 20 ft wide and 18 ft high. Larger size doors should preferably be motor operated for more rapid opening and closing.

Ventilators Ventilators through the roof should be provided that comply with local requirements. Ventilators are either continuous ridge type or individual round types distributed over the roof area. Some rotary types are available that are activated by the wind, and in cases where large changes of air are necessary, mechanical forced-air systems are used.

Offices and Washrooms When warehouses are located near transit sheds or other marine buildings, there is seldom any need for offices or washrooms. This is particularly true if various operators use the warehouse. In the event that one operator leases the entire facility, it may be advantageous to incorporate offices and washrooms.

Protection Devices Structural columns in the interior of the warehouse should be protected from damage caused by collision with vehicles by enclosing the lower 4 to 6 ft in concrete or by setting heavy steel pipe guards around them. Likewise, main switchboards should have protective barricades, either pipe railings or concrete-filled steel posts, set about 3 ft out in front to act as a protection against motorized handling equipment.

Sprinkler risers, valves, and control mechanisms should be enclosed in a structural-steel framework covered with heavy diamond mesh screening. This will prevent any stored material from accidentally falling on the sprinkler equipment and causing it to be damaged or rendered inoperable.

WAREHOUSES—WATERFRONT

Painting

Warehouses constructed of reinforced concrete need not have the enclosing walls painted. However, metal doors, windows, coping, and flashings should be painted with a good grade of exterior paint. There are several new paints on the market now that provide remarkable protection against corrosion even in the saline atmosphere of the seacoast.

Corrugated sheet-metal buildings are definitely improved in appearance by the application of paint, and the useful life of the metal is extended.

Painting the inside of warehouses improves the general lighting effect, and makes working conditions safer.

Fire-hose racks and automatic-sprinkler risers should be painted a brilliant red for ready identification. Overhead signs designating the location of electric panel boards, exit doors, and other facilities are an added convenience. Lines painted on the floor defining main aisles, cross aisles and storage areas, and "Keep Clear" areas are helpful when stacking cargo. In many warehouses smoking is prohibited, in which case "No Smoking" signs should be prominently displayed.

Fire Protection

Warehouses should be protected with a complete automatic-sprinkler system meeting the requirements of the National Board of Fire Underwriters. Wherever possible, a supervisory fire-alarm circuit connected to the local fire department alarm circuits should be provided so that in case of fire the fire department is immediately informed.

Auxiliary fire equipment such as hose racks and chemical fire extinguishers should be located at several locations in the building and be clearly designated by being painted bright red. Stacking

of cargo should be so arranged that all fire equipment is easily accessible at all times.

Lighting

Natural Lighting The best source of light for a warehouse during the daytime is natural light or sunlight. There are two methods available: (1) roof lighting and (2) sidewall lighting.

Roof lighting can be accomplished by means of (a) monitors, (b) skylights, or (c) sawtooth construction.

A combination of monitors and sawtooth construction provides very good lighting and has long been an accepted method of design. Skylights, if symmetrically spaced and a sufficient number installed, give equal distribution of light throughout the building. Skylights are sometimes a source of roof leakage and should be carefully designed and installed to insure a weathertight condition. In recent years plastic dome-type skylights have become quite popular. They come in various shapes and sizes and are readily installed on composition-type roofs and are easily made weathertight.

To maintain the desired transmission of light, all roof lighting, whether monitor or skylight, should be hosed off frequently to maintain a clean surface.

Windows can be installed in the side walls to provide additional light and in buildings using corrugated Fiberglas panels, either clear or translucent, that will member with the siding and provide a continuous band of light on each side of the building. All forms of side-wall lighting are subject to being blanked off by the high stacking of cargo and consequently should not be depended upon entirely to provide the desired day lighting.

Artificial Lighting For night operation and to supplement natural light during the daytime, electric illumination should be provided. The light level should not be less than 10 foot-candles. The spacing of lights is very important and should be designed to provide adequate lighting in the aisles at all times even when cargo is stacked high. Sufficient switches should be provided to allow lights to be switched on only in certain areas where work is being done. If watchman service is maintained or when only minimum illumination is desired, separate light circuits should be installed with control switches conveniently located near entrance doors.

Type of Fixtures The fixtures that can be used are (1) incandescent, (2) fluorescent, and (3) mercury vapor. There are advantages and disadvantages in each type.

Incandescent lamps need replacing frequently, and the convection currents set up by the hot globe cause the reflector and the light globe to become coated with dust, reducing the illumination considerably.

Fluorescent-tube lighting is becoming more popular since high-output fluorescent lamps have been developed which produce the increased illumination desired. Upkeep is still a problem with them as tubes become blackened with resultant loss of efficiency.

Mercury-vapor lighting is the most efficient, provided that sufficient mounting height can be obtained. Mercury-vapor lights require time to warm up before full illumination, so they cannot be turned on and off as readily as incandescent or fluorescent lights. In warehouses where different color codes are used on the stored cargo it is very important to use color corrected mercury

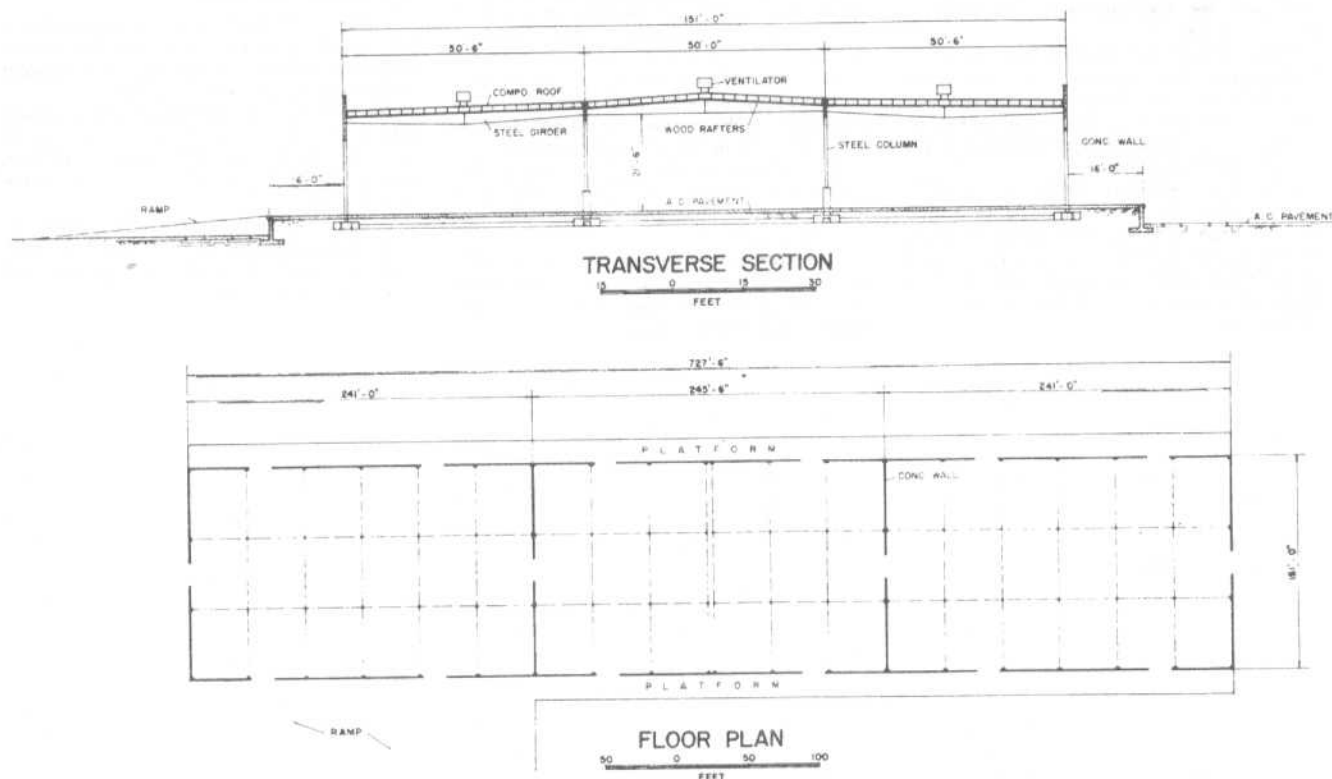

Fig. 1 Typical warehouse, Port of Long Beach, California.

WAREHOUSES—WATERFRONT

vapor lamps in order to be able to read the various color codes.

When any truck loading is accomplished at night, outside floodlighting of the area is essential. For safe operation, the intensity of illumination should be at least 1 foot-candle and preferably 2 foot-candles. Mercury-vapor lighting lends itself ideally for this situation as high-intensity lights can be mounted on steel poles to provide even illumination. At loading platforms lights can be mounted over doorways or on the building parapet to illuminate the platform and the trucks or railroad cars.

Wiring Before designing the electrical wiring system, the public utility company supplying the electric current should be consulted in order to determine the various systems available. The standard 120/240-volt three-wire system is adaptable to all three types of lighting. If considerable power for motors or heating is required, the 208/120-volt three-phase system would be desirable. The 480/277-volt four-wire system is adaptable to either mercury-vapor or fluorescent lighting, and considerable reductions in wire size, conduit size, and panel boards can be effected by its use. For large buildings this could mean a considerable saving in cost of the electric system. If small 120-volt single-phase loads are required, dry-type step-down transformers can be located adjacent to the sub-panel board.

Port of Long Beach, California

A plan and cross section of a warehouse at the Port of Long Beach is shown in Fig. 1.

The building is 151 ft wide and 727.5 ft long with a gross area of 109,852 sq ft. It is divided into three separate and approximately equal storage areas by 12-in-thick precast reinforced concrete transverse fire walls. Columns at the exterior walls and fire walls are reinforced concrete, poured-in-place.

Interior columns are structural steel spaced 50 ft apart, and column bays are spaced 40 ft apart.

Roof trusses and girders are of steel and support a system of 2-in by 10-in wood roof joists, ½-in plywood diaphragm roof sheathing and a built-up composition roof.

The side and end walls contain a total of 14 vertical rolling steel doors measuring 16 ft wide by 16 ft high. Openings through the fire walls on the centerline of the building are protected by automatic self-closing vertical rolling steel fire doors 16 ft wide and 16 ft high on each side of the wall.

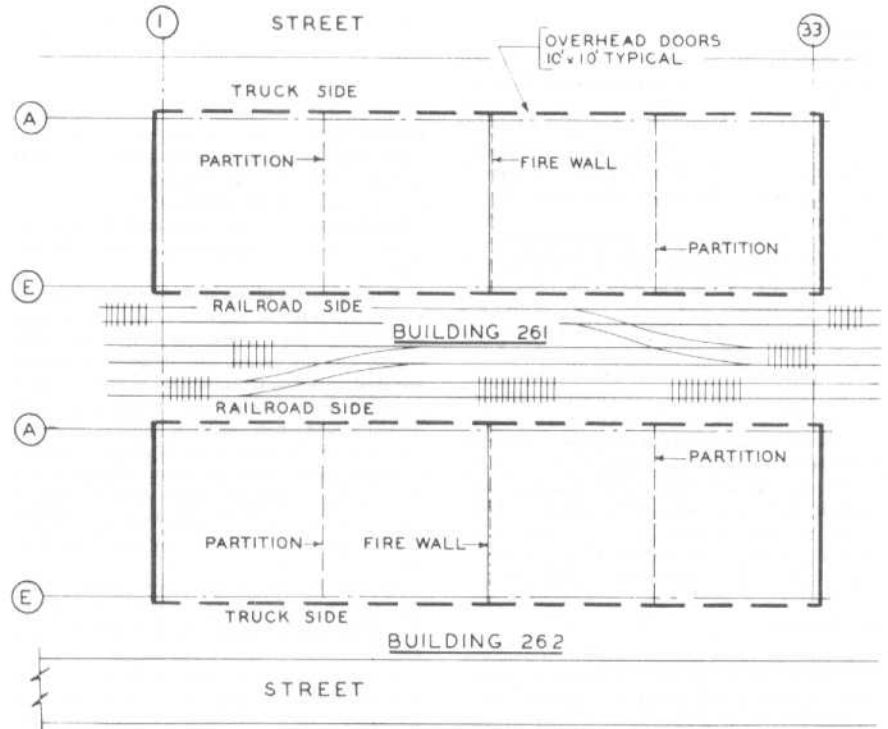

Fig. 2 Port Newark, New Jersey. Typical warehouse layout for efficient utilization of rail and truck service, cargo distribution buildings.

Truck and rail loading platforms 16 ft wide are on each side of the building with one-third of one side ramped to permit direct access into the building by vehicles.

There are no skylights or monitors on the roof or windows in the side walls. Distributed symmetrically over the roof area are 54 circular ventilators that provide the required air changes.

Artificial lighting of the interior is accomplished by 400-watt mercury vapor fixtures. All exterior loading areas are floodlighted with 400-watt mercury vapor lights.

A complete automatic sprinkler system with supervisory electric circuits is installed throughout the building, and in addition hose reels are mounted at convenient locations.

Port Newark—New Jersey

The plan in Fig. 2 illustrates typical warehouse layout utilizing modern rail and truck service. The warehouse floors are at truck and rail-car heights to facilitate easier cargo handling.

The buildings are 160 ft wide and vary from 640 ft to 960 ft long. The column spacing is 40 ft with bents every 20 ft, and the minimum interior clear height is 20 ft. The roof slope is on a 2½ on 12.

Buildings have been constructed of either structural steel or structural timber frames with aluminum roofing and siding. Plastic skylights are used to provide natural light.

PHYSICAL PLANNING

Coordination in the Preparation of the Airport Layout Plan

If the airport is considered a suitable location for an airport industrial park, the industrial park's location and land requirements should be taken into account during the preparation of the airport layout plan.

Economy of layout and operations requires that the airport industrial park be one contiguous area. In order to achieve this contiguity, careful study of the other airport land requirements must be made. It is advisable to free the maximum amount of land for industrial development consistent with retaining full expansion capability for essential airport uses such as aircraft movement areas, passenger and freight terminals, aircraft parking aprons, navigation aids, automobile parking areas, and aircraft maintenance areas.

Location on the Airport

The land available for development for an airport industrial park should be located so as to take full advantage of its airport situation.

A location which often is a good choice for the industrial park is on the side of the runway opposite the terminal. This is particularly true at airports used by air carriers, where diversion of industrial traffic from the terminal traffic boulevard is advisable. Also, in this area, airport supporting services are not competing for land to use for activities such as terminal auto parking and commercial concessions. (See Fig. 1.)

A location in the vicinity of the general aviation area has the advantage of being close to the area where the aircraft will be stored and maintained. This location keeps ground taxi time at a minimum. (See Fig. 2.)

Taxiway Access

The taxiway system connecting the aircraft movement areas with the individual units of the industrial park should be decided upon in the early stages of planning. The access routes are a determining factor in the development pattern. Proper planning of these traffic lanes will conserve land valuable for other uses—uses more productive of revenue. Determination must be made at an early stage of the proportion of the tract to be served by taxiways to the aircraft movement area of the airport. The airport owner reserves the right to establish a user charge for the privilege of access through these taxiways to the common use landing area.

Opinion is divided as to the necessity of providing taxiway access to each lot because of the relatively large amount of land this requires. In most cases a compromise can be reached by providing access to those lots

closest to the aircraft movement areas. A 50-ft service taxiway within a 150-ft right of way is generally sufficient for business aircraft. To minimize conflict with the street system, it is recommended that the taxiway right-of-way be located at the rear of the lots served and that the blocks be long and narrow to reduce the number of intersections between streets and taxiways. (See Fig. 1.)

Two interesting variations for providing access to the aircraft movement areas are:

1. A taxiway provided to those lots directly abutting the aircraft movement areas. (See Fig. 3.)
2. A taxiway into an aircraft parking apron which is surrounded by industrial lots. (See Fig. 4.)

In projects where no taxiway into the airport industrial park is provided, reasonable accessibility can be had by locating the industrial area in close proximity to the general aviation apron. (See Fig. 5.)

Railroad Access

If rail service is available to the site, a 20-ft right-of-way is sufficient for a single track spur. Determination should be made in advance of the proportion of the lots to receive rail service. The rail service right-of-way should be located on the opposite end of the lots from the vehicular right-of-way.

Contact with the railroad serving the area should be made to assure construction that will meet the railroad's standards. In most cases, cost of the railroad spur will have to be paid for by the management of the industrial park, but there are instances when the railroad has paid the cost of the spur track. Usually, if the railroad spur is paid for by the railroad, title to the right-of-way will have to be passed to the railroad.

Street System

The widths of the right-of-way and the pavement depend on the anticipated traffic demand. Excessive pavement width, in addition to its high cost, has the tendency to encourage on-street parking which creates traffic problems. Minimum pavement widths and strict enforcement of on-street parking prohibitions are recommended.

Curbs and gutters rather than drainage ditches are recommended in order to keep the right-of-way width to a minimum; these will facilitate drainage of the site and also assure a cleaner, more attractive site.

Airport industrial parks surveyed show considerable variation in the widths of pavements and rights of way selected. With enforcement of on-street parking prohibitions and the use of curbs and gutters, the right-of-way should be a minimum of 40 ft for a 24-ft (2-lane) pavement. These dimensions are sufficient for secondary streets. Additional lanes are required in larger developments to add capacity to meet peak hour demands. For larger developments, on streets which will have a substantial number of industrial installations, a 60-ft

right-of-way is recommended so that two additional lanes of traffic can be added when the demand warrants.

For primary feeder streets, a minimum of 48 ft of pavement within a 60-ft right-of-way is recommended.

Street intersections should have a curb radius of at least 40 ft to accommodate tractor-trailer vehicles.

It is recommended that the number of entrances into the industrial park be as few as possible to discourage use of the circulation system by traffic which is not directly related to the park. The entrances should be from a public thoroughfare with at least equivalent capacity and be separate from the airport entrance road in order to avoid traffic mix with those vehicles serving or visiting the airport.

Off-Street Parking and Loading

Off-Street Parking This should be provided for all vehicles which come into the airport industrial park. Parking spaces should be provided for employees, visitors, company vehicles and all trucks.

Employee Parking In airport industrial parks virtually all employees drive to work. Consideration should be given to overlapping requirements of successive shifts. Provision should be made for one parking space for every 1.3 employees on the combined shifts. Allowance of 300 square feet should be made for maneuvering and parking each vehicle.

Visitor Parking Parking space for visitors should be provided at the rate of one parking space for every 15 employees on the main shift.

Company Vehicles Provision of one parking space for each company vehicle is recommended.

Truck Loading Docks Loading docks should accommodate truck trailers and local pickup trucks. To accommodate truck trailers, berths should be 14 ft wide by 60 ft deep with an additional depth of 60 ft for maneuvering. For local pickup trucks, berths 10 ft wide by 20 ft deep are sufficient with a 20-ft additional depth for maneuvering. Loading docks should not be located on the street side of the building.

Entrance Driveways Entrance driveways for truck access should be offset from the truck parking ramp to prevent trucks from backing from the street into a loading dock. Curb radii of 25 ft minimum are recommended for truck access drives. Driveways for automobiles should have minimum curb radii of 15 ft.

Building Setbacks

The airport industrial parks surveyed indicate a variety of setback standards which are generally related to the size of the lots in the particular developments. Aesthetic considera-

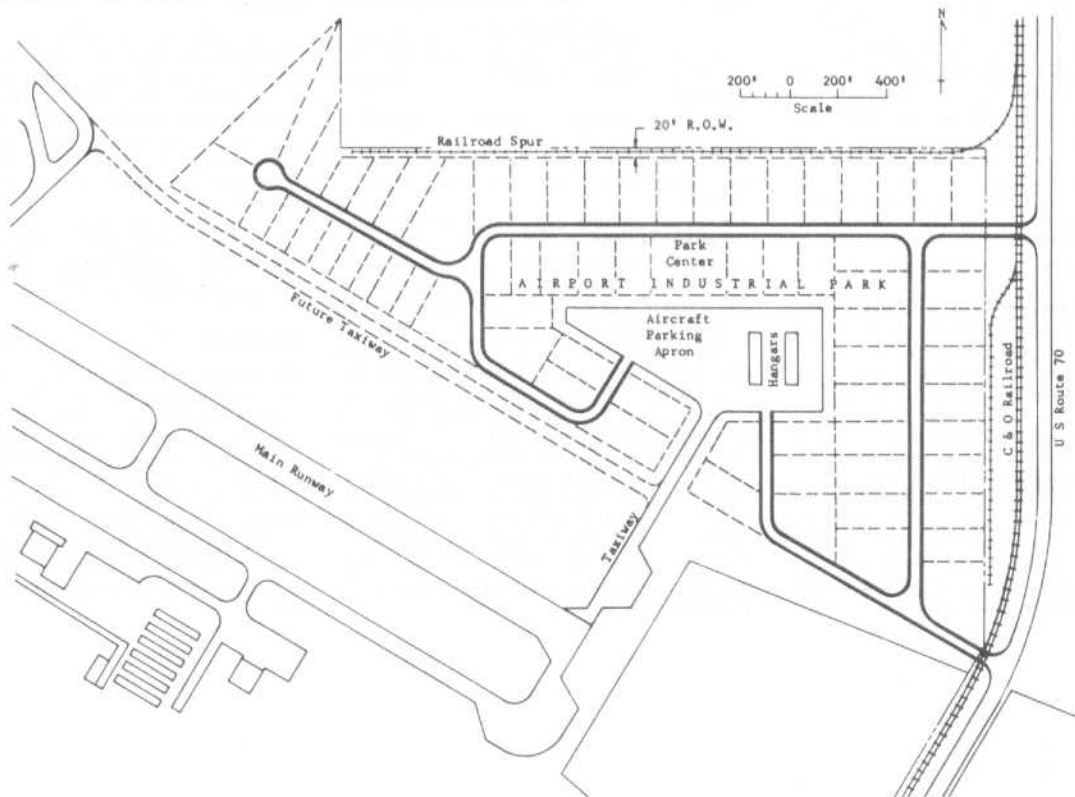

Fig. 4 Industrial park with taxiway into aircraft parking apron surrounded by industrial lots.

AIRPORT INDUSTRIAL PARK

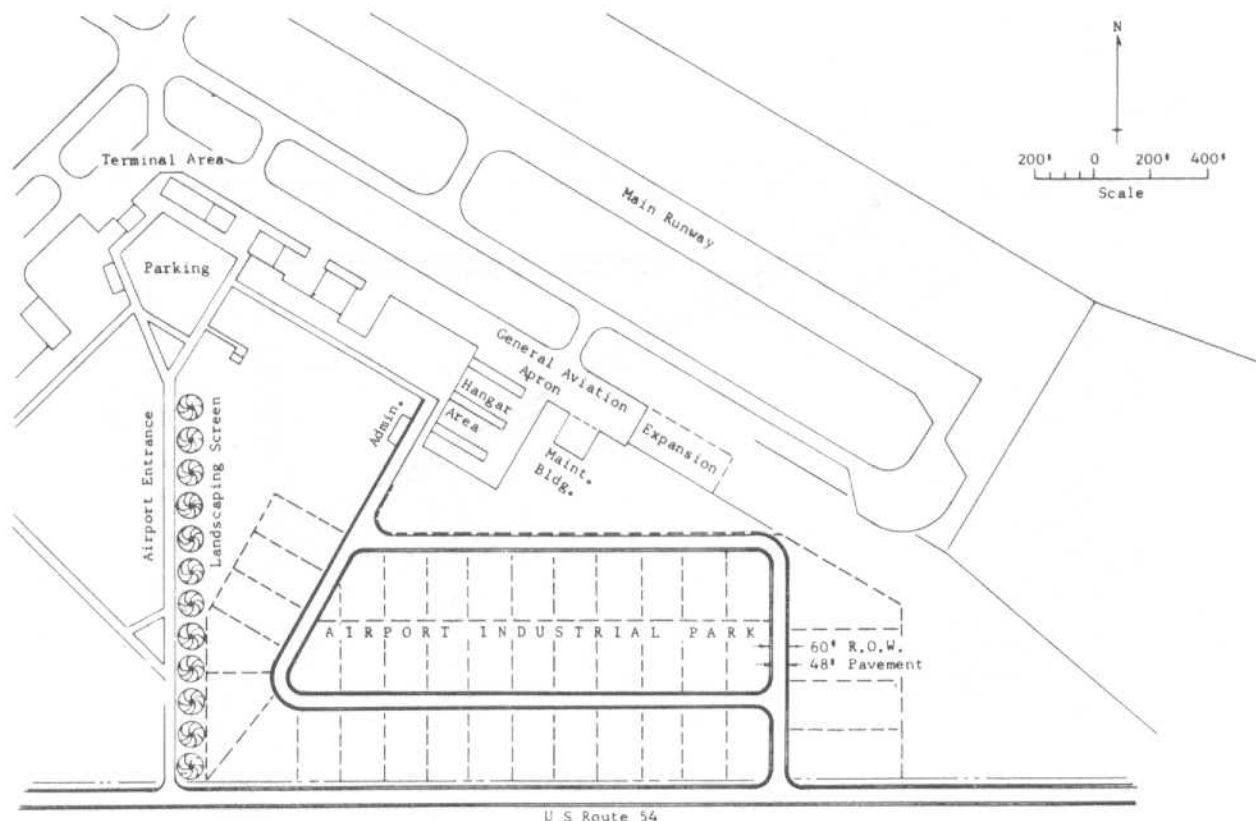

Fig. 5 Industrial park without taxiway access located adjacent to the general aviation area.

tions are significant and no single set of standards will be applicable to all airport industrial parks. The main goal is to retain a feeling of open space in the development. In addition, setbacks may be related to the topography, rougher terrain generally requiring greater setbacks to minimize the amount of site work to the developer and to neighboring tenants. On most airports, the land developed for industry will be relatively flat, which would permit setbacks to be the minimum required for aesthetic considerations, free movement of fire apparatus around structures and meeting the requirements of local ordinances.

A 30-ft front setback from the property line, using the street rights-of-way previously discussed, will allow approximately 36 to 48 ft from the edge of the street pavement. This should be sufficient in projects where the smallest lots are $\frac{1}{2}$ acre or less.

Side and rear setbacks of at least 25 ft are recommended for fire safety separation, aircraft clearance and architectural harmony.

A further measure that is recommended for assuring the parklike quality of the development is to limit the amount of each site permitted to be occupied by structures. Site coverage of 60 percent should be a maximum although 50 percent is preferable.

Site Layout

An airport industrial park should be at least 50 acres to justify the management effort required for planning, promotion, and continuing operation.

Block dimensions are determined in part by the depths established for groups of lots. Within the block it is then possible to adjust lot widths to suit the needs of individual tenants.

A variety of block sizes based on lot depths of 150 ft up to 500 ft allows for inclusion in the project of sites varying from about $\frac{1}{2}$ of an acre to 10 acres. Minimum lot width should be about 100 ft in order to provide buildable sites for small industries.

It is recommended that blocks be as long as practicable to reduce the costs incurred in the construction of cross streets. Within the industrial park, there is little need for lot-to-lot circulation because most traffic is to and from destinations outside the industrial park.

Stage construction usually is a necessity because of flexibility and cost considerations. Sections that are opened for development should be improved so that lots offered for lease or sale are developed lots rather than raw land. Streets and utilities should be provided ready for use at the sites.

Utilities

Utilities that are essential are water, sanitary sewer system, electric power, gas distribution, fire hydrants and storm sewers adequate for drainage on and off site. Utilities are provided by the sponsor through his own resources, or by arrangement with the local utility companies, so that the tenant is only required to connect his installation to existing systems.

Utility easements may be provided in the rights-of-way reserved for streets or rail spurs. Underground utilities may be provided in aircraft taxiway rights-of-way.

Park Center

Reservation of an area for a park center should be made in larger projects. This center would include the offices of the park management and maintenance functions. Facilities for the common use of park tenants could be offered, such as restaurant, banking facilities, small shops for sale of sundries and, possibly, motel facilities for the accommodation of overnight guests. Other commercial services and personal conveniences could be provided at the discretion of the park management in the park center.

DESIGN OF FACILITIES

Site Selection

Amid the many other factors influencing the choice of an industrial plant site, that of employee parking should not be overlooked. Site requirements, in some cases, may be prescribed by equal areas each for factory, storage, and parking. But parking needs frequently are affected by the type of location, since the demand for parking often may be less in locations where land costs are highest. The influences of transit service, walk-to-work trips, or drop-off trips, which are likely to be related to area type, are suggested in the table on this page.

The example shows that parking area needs for 1,600 employees may vary by as much as three acres. The total cost for employee parking may be equal or less at the rural site, however, because of lower land costs.

When land costs are high, it becomes more economical to build a second level over existing parking than to construct new surface lots. Other economic factors, such as proximity to markets or to rail service, may overcome the disadvantages of high parking costs in urban areas. Roof parking or remote parking with shuttle bus service are other solutions to meeting parking demand at confined plant sites.

Another principal traffic factor influencing site selection is the capacity of street systems to absorb peak hour loads at shift changes. While a concern primarily of public agencies, plant management is also concerned in terms of labor market accessibility as well as the ease of transporting incoming materials and outgoing products.

Design Elements

Several principles control the design of industrial plant parking facilities. First, the unique characteristics of employee parking must be taken into account. Unlike parking at shopping centers, airports and many commercial lots, industrial plant parking is characterized by long-term parking, nearly simultaneous large volumes of arrivals and departures, and brief periods of vehicle-pedestrian conflict.

Design provisions should, therefore, satisfy the following requirements:

1. Stall size that accommodates current vehicle models
2. Stall arrangements that make judicious use of the area available
3. Access to individual stalls that is safe, convenient and without delay
4. Entrances and exits that minimize delays
5. Parking locations that are close to working areas
6. Security and aesthetic treatments that meet plant and public needs

Stall Size Vehicle dimensions are the principal determinant of stall sizes. Many current models of automobiles measure 80 in. in width and 218 in. in overall length. Door-opening characteristics are another factor. As two-door models, which have larger doors than four-door models, become even more popular, there is an increasing need for wider stalls in parking facilities.

The 1959 ITE Recommended Practice on Industrial Plant Parking recommended 8-ft 6-in. stalls, which under present conditions may allow only 22 in. between vehicles for door opening. Current prevalent practice is to employ 9-ft stalls, with 10-ft stalls in some 90° visitor parking layouts. The effects of increasing stall width from 8 ft 6 in. to 9 ft, considering a 500-ft bay are as follows: with 90° parking, a reduction of from 58 to 55 spaces; with 60° parking, from 50 to 47 spaces.

When stall widths are less than 9 ft, double lines between stalls will assure better positioning of vehicles and minimize the possibility of wasted spaces due to improper parking.

Stall lengths must be at least 18 ft to accommodate current vehicle models. If "drive-through" parking is employed, stall length may be increased to 19 ft to allow for some clearance between vehicles.

Clearance from walls, fences, roadways or walkways can be maintained by using curbs or wheel-stops properly positioned within the stall area. A front overhang of 3 ft and a rear overhang of 5 ft are typical values to be accommodated.

Stall Arrangements Decisions about the choice of angle and the layout of aisles must be based on individual site conditions. The placement and number of entrances and exits, and the site shape and contour are the major controls. At large plants, blocks of parking by groups of three to five hundred cars are preferable to larger aggregations. Pedestrian-vehicle conflicts can be reduced, and assigned parking for different shifts and employment groups can be better controlled, through the use of such relatively small blocks.

The following general practices are desirable: use natural grades to facilitate drainage; provide for counterclockwise traffic aisle flow, since left turns are easier than right turns for drivers; have parked vehicles face downhill rather than uphill, to allow for stalled vehicles or winter weather conditions.

This report includes layout details for only one type of parking. Figure 1 illustrates a stall arrangement and an aisle design that have not been widely published—the drive-through double stall pattern, usable in either 90° or acute angle parking layouts.

In general, angle parking is preferred for large industrial parking facilities. First, properly designed angle parking can employ space as effectively as right-angle parking. Second, it virtually forces one-way movements, thereby simplifying control, reducing conflicts, and ensuring that daily parking practices conform to the established design. Third, it provides for easier turning movements into and out of stalls.

Drive-through angle parking design offers the further advantages of minimizing backing out of stalls and directing all aisle travel in the same direction. It conserves space more effectively than other angle parking designs. Typically, the angled drive-through layout requires 36 ft for the double stall and an 18-ft aisle (to permit passing stalled vehicles), for a unit parking depth of 54 ft. Compared with 90° parking, the space loss along the length of the bay—eight spaces in 500 ft according to the example—will be compensated for by the reduction in unit parking depth, from 62 or 64 ft to 54 ft, if enough bays can be used.

The disadvantage of this design of drive-through parking is that it increases the travel distance and time of a search pattern if the lot is nearly full. It also is imperative to keep the end circulation aisles two-way so that a driver will not be forced out of the lot in order to return to another parking aisle.

The drawing also gives dimensions for angle parking at 53° 8', an angle which has the layout convenience of being a 3-4-5 triangle. Other angles commonly used for parking are 45, 55, or 60°. However, any angle smaller than the 3-4-5 configuration tends to be wasteful of space, without offering any significant advantage.

Where two-way aisle flow may be desirable, as in visitor parking lots, 90° parking is more appropriate. Site dimensions sometimes may be such that 90° unit parking depths are most appropriate regardless of other circumstances. The minimum 90° parking depth reported to Committee 6T was 61 ft, with preferences expressed for 62-64 ft as desirable dimensions. When unit parking depths are less than desirable, shortened stall lines (10-15 ft long) may encourage drivers to pull all the way into stalls.

Hypothetical Relationship of Parking Area Requirements to Location

Location	No. of employees at peak shift overlap	Percent as drivers or auto psgrs.	Number of autos to be parked*	Approx. site, sq ft	Area, acres
Urban	1,600	60	740	222	5.0
Suburban	1,600	80	990	297	6.8
Rural	1,600	95	1,180	354	8.0

* Assuming car occupancy of 1.3 persons per car.

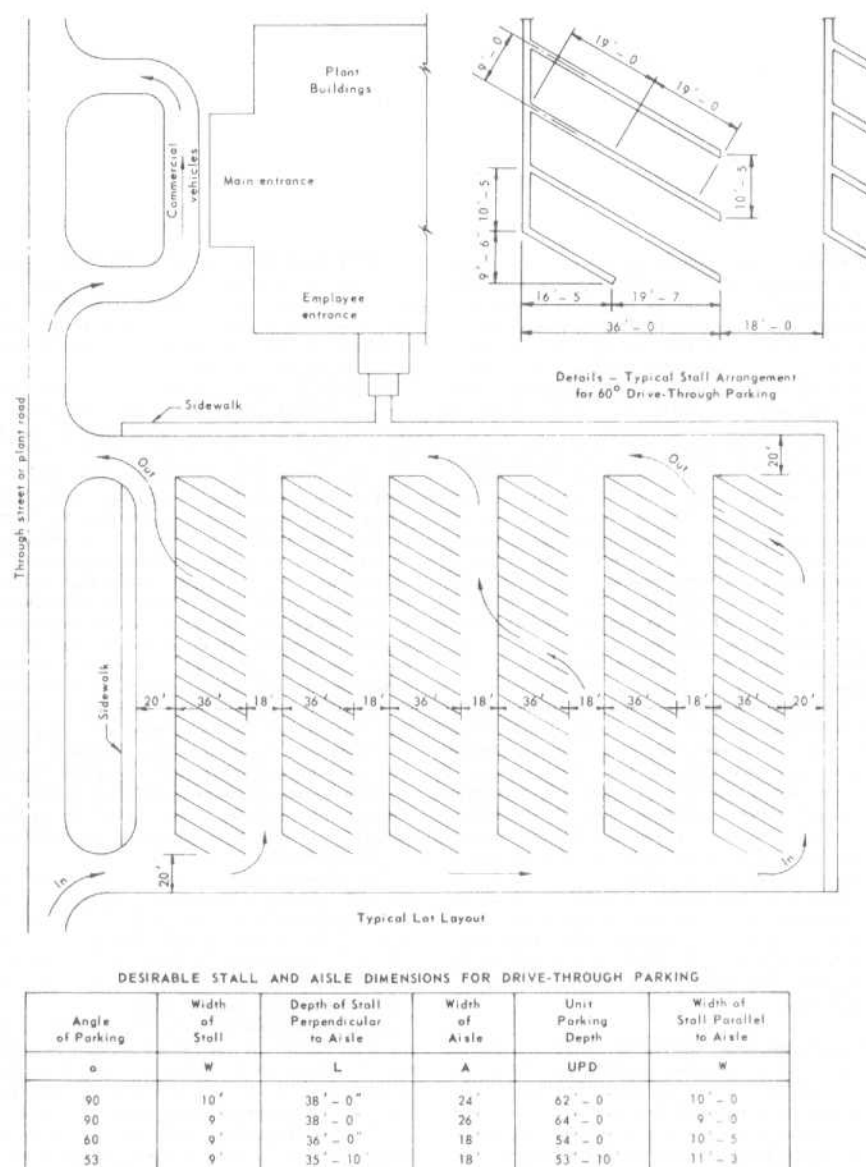

Fig. 1 Drive-through lot layout.

Service Roads Many large plants require service roads between plant entrances and parking areas. Several design factors may be noted:

1. Proper control can best be achieved if service roadway lanes are clearly marked for one- or two-way operation.
2. To permit passing of a stalled vehicle, one-way, single-lane service roads must be at least 18 ft wide.
3. Incoming shift vehicles should be separated from truck deliveries and outgoing shift vehicles.
4. Service roads that permit drivers to reach those plant exits most suitable for their subsequent travel direction will minimize conflicts and capacity reduction at plant exits.
5. Pedestrian conflicts can be minimized by locating the entrances from service roads in parking areas at the end opposite to work areas.

6. Exits from parking areas to service roads will minimize conflicts if they are placed away from the main stream of pedestrians leaving work.

Plant Entrances and Exits The number and location of gates is a function of both the external roadway system and internal circulation. It may be desirable, or even necessary, to distribute peak-hour volumes among several streets to avoid overtaxing the capacity of nearby intersections. In the case of overlapping shift arrivals and departures, both internal and external conditions will dictate to a large degree the number and location of gates. Because exit peaks generally are of shorter duration, greater exit than entrance capacity usually will be required. Exit turning movements also may be less efficient, in vehicles cleared per hour, than entrance movements.

The total number of exits will be determined

by the number of lanes available at individual exits, what turns may be prohibited, and the allowable length of time for discharging peak period volumes. Observed exit rates for left- and right-turning lanes range up to 1,500 vehicles per lane per hour of green time.¹ Obviously, nearby highway intersections must provide adequate capacity to meet exit volumes in addition to nonplant traffic. A traffic engineering analysis employing the type of procedures outlined in the Highway Capacity Manual may be necessary to ensure the most effective location and design. Such an analysis certainly should be undertaken when traffic signals are contemplated, or when volumes reach magnitudes for which grade separation may need to be considered.

Where two-way flow is to be accommodated, the roadway width at gates should be at least 26 ft to facilitate turning movements to or from a major highway. The American Association of State Highway Officials design policies may be consulted for turning radii details.² Where guards stop incoming vehicles, checkpoints should be far enough from the highway to prevent queues forming on the highway.

Pedestrian Needs

Pedestrian-vehicle conflicts are almost inevitable, but with minimum walking distances such conflicts can be reduced. Several methods can be followed to lessen the inefficiency, congestion and safety hazards inherent in such conflicts.

1. Parking space allocations can be oriented to specific buildings.
2. Parking areas may be designed to focus on major walkways, which should be fenced or marked.
3. Where pedestrians must cross service roads or access roads to reach parking areas, crosswalks should be clearly designated by pavement markings, signs, flashing lights, or even traffic signals operated by plant security personnel. Crosswalk surfaces may be raised slightly to designate them to drivers, unless drainage problems would result.
4. Walkways may be provided under cover of buildings between parking and work areas.
5. Wherever possible, parking aisles should lead directly to the plant. This will minimize inbound problems, since close-in spaces will be taken first and later arrivals will park farther away. Pedestrians can walk past parked cars rather than crossing aisles with cars arriving and being parked.

The best means of separating pedestrians and vehicles is by constructing underpasses or overpasses at key points. Grade separation may be essential to prevent long delays and time losses, as where freight must be handled, to avoid exposure to hazardous plant operations. It may be necessary where parking facilities and plant buildings are on opposite sides of major highways. If intersection capacity problems preclude provision of a pedestrian phase in nearby traffic signals, grade-separated pedestrian crossings will be essential.

Provisions for Commercial Vehicles

Receiving and shipping needs of many industrial plants are accommodated by motor trans-

¹ Highway Research Board, "Highway Capacity Manual," Special Report #87, 1965, page 137, Washington, D.C.

² American Association of State Highway Officials, "A Policy on Arterial Highways in Urban Areas," Washington, D.C., 1957.

INDUSTRIAL PLANTS, PARKING

port vehicles, ranging from pickup trucks to five-axle tractor-trailer units. While the major movements involve raw materials, supplies, and finished products, a measurable amount of truck traffic is generated also by canteens, cafeterias, laboratories, or other service needs.

Unless an industrial plant is under strict security measures, motor transport vehicles normally use the same entrance and exit facilities used by employee vehicles. Where security is a question, separate truck gates may be provided with each inbound and outbound truck being checked by a guard. Gates used by trucks require two lanes, each 12 ft in width, clearly posted as to use. Controls may be required to eliminate possible conflict between trucks and other traffic, especially at periods of major employee shift arrivals and departures. The most effective control at periods of peak demand is prohibition of all commercial vehicles.

Within plant premises, it is desirable to route commercial vehicles around the periphery of the plant to loading areas and to prohibit direct access through employee parking lots. The width of driveway lanes should be not less than 10 ft nor more than 12 ft, in order to discourage illegal parking. Turning radii should be adequate for the largest vehicle anticipated, and signs and markings should conform to accepted standards.

This report does not treat the design of loading docks in detail, but the following informational comments are offered. The width of apron space or maneuvering area in front of loading docks is dependent upon the overall length of servicing vehicles, the turning radii of the

equipment and the width of truck berths. Generally, the distance from the edge of the loading dock to the opposite curb, outside edge of opposite truck berths, or near edge of any physical obstruction, should equal not less than twice the overall length of the longest service vehicle. Where receiving or shipping operations necessitate an accumulation or storage of trailer units in excess of available dock apron space, a marginal area should be provided for waiting or for trailer storage separate from the apron space or any parking lot. Apron areas should be free of any passenger car parking and physically separated from any portion of the parking lots. The surface should be well paved with a dustless and durable material, graded for drainage and of sufficient bearing strength to support concentrated axle loads.

Amenities

Both employee and community relations may require that some consideration be given to parking area amenities. Much depends on location. A steel mill surrounded by steel mills will not be concerned in the same way that an electronics plant next to suburban residential areas need be.

Landscaping can be an important element in the appearance and effective use of parking areas. It can serve functionally by designating separate parking areas: aesthetically by breaking the bleakness of great expanses of asphalt.

Utilities often can be placed in landscaped areas. Some plants take landscaping amenities

so seriously that preferred parking layouts may be rejected because of insufficient landscaping. There are several drawbacks to be considered, however. Improperly located shrubs may seriously reduce driver sight distances. High plantings that completely screen employee vehicles may encourage vandalism and pilferage. Deciduous trees may create trouble with sap droppings; falling leaves increase maintenance costs and also may obstruct drainage structures. In colder climates, landscaping may impede snow removal.

Noise control is sometimes an important factor. Plant noise may be materially reduced by proper location of loading docks and parking areas, although even the quietest truck is disturbing at night. Depending on terrain, noise may be buffered by fences or planting.

Lot surfacing may be an amenity factor. All lots should be properly graded for drainage and should be dust-free. Higher type surfaces, with pavement markings to designate spaces and reserved areas, may be warranted in high-land-cost areas, and at activities attracting many visitors. A more efficient as well as a more attractive site will result.

Some amenities may help to reduce the total number of parking spaces required. Covered or shielded transit waiting areas, within close walking distance of buildings, may encourage a higher level of transit usage. Alternatively, shuttle buses might be operated between transit stops and plant areas. Providing turnout bays where auto passengers may be dropped off and picked up may mean that otherwise necessary parking space can be put to a more productive use.

General

Playlots should be provided for preschool children up to 6 years of age primarily in conjunction with multifamily (townhouse and apartment) developments and in single-family neighborhoods remote from elementary schools. They are a necessary element of such developments to complement common open-space areas. Playlots may include (1) an enclosed area for play equipment and such special facilities as a sand area and a spray pool; (2) an open, turfed area for active play; and (3) a shaded area for quiet activities.

Location of Playlots

Playlots should be included as an integral part of the housing area design, and are desirably located within 300 to 400 ft of each living unit served. A playlot should be accessible without crossing any street, and the walkways thereto should have an easy gradient for pushing strollers and carriages. Playlots may be included in playgrounds close to housing areas to serve the preschool age group in the adjoining neighborhood.

Size of Playlots

The enclosed area for play equipment and special facilities should be based on a minimum of 70 sq ft per child, which is equivalent to 21 sq ft per family on the average basis of 0.3 preschool child per family. A minimum enclosed area of approximately 2,000 sq ft will serve some 30 preschool children (about 100 families). Such a size will accommodate only a limited selection of play equipment. To accommodate a full range of equipment and special facilities, including a spray pool, the minimum enclosed area should be about 4,000 sq ft, which would serve up to 50 preschool children (about 165 families). Additional space is required to accommodate the elements of the playlot outside of the enclosed area, as listed in the next paragraph. A turfed area at least 40 ft square should be provided for active games.

Playlot Activity Spaces and Elements

A playlot should comprise the following basic activity spaces and elements:

1. An enclosed area with play equipment and special facilities including
 - a. Play equipment such as climbers, slides, swing sets, playwalls and playhouses, and play sculpture
 - b. A sand area
 - c. A spray pool
2. An open, turfed area for running and active play
3. A shaded area for quiet activities
4. Miscellaneous elements, including benches for supervising parents; walks and other paved areas wide enough for strollers, carriages, tricycles, wagons, etc.; play space dividers (fences, walks, trees, shrubs), a step-up drinking fountain, trash containers, and landscape planting.

Layout of Playlots

The specific layout and shape of each playlot will be governed by the existing site conditions and the facilities to be provided. General principles of layout are described as follows:

1. The intensively used part of the playlot with play equipment and special facilities should be surrounded by a low enclosure with supplemental planting, and provided with one entrance-exit. This design will discourage intrusion by animals or older children, provide adequate and safe control over the children, and prevent the area from becoming a thoroughfare. Adequate drainage should be provided.

2. Equipment should be selected and arranged with adequate surrounding space in small, natural play groups. Traffic flow should be planned to encourage movement throughout the playlot in a safe, orderly manner. This traffic flow may be facilitated with walks, plantings, low walls and benches.

3. Equipment which enables large numbers of children to play without taking turns (climbers, play sculpture) should be located near the entrance, yet positioned so that it will not cause congestion. With such an arrangement, children will tend to move more slowly to equipment that limits participation and requires turns (swings, slides), thereby modifying the load factor and reducing conflicts.

4. Sand areas, play walls, playhouses, and play sculpture should be located away from such pieces of equipment as swings and slides for safety and to promote a creative atmosphere for the child's world of make believe. Artificial or natural shade is desirable over the sedentary play pieces, where children will play on hot days without immediate supervision. Play sculpture may be placed in the sand area to enhance its value by providing a greater variety of play opportunities. A portion of the area should be maintained free of equipment for general sand play that is not in conflict with traffic flow.

5. Swings or other moving equipment should be located near the outside of the equipment area, and should be sufficiently separated by walls or fences to discourage children from walking into them while they are moving. Swings should be oriented toward the best view and away from the sun. Sliding equipment should preferably face north away from the summer sun. Equipment with metal surfaces should be located in available shade.

6. Spray pools should be centrally located, and step-up drinking fountains strategically placed for convenience and economy in relation to water supply and waste disposal lines.

7. The open, turfed area for running and active play, and the shaded area for such quiet activities as reading and storytelling, should be closely related to the enclosed equipment area and serve as buffer space around it.

8. Nonmovable benches should be conveniently located to assure good visibility and protection of the children at play. Durable trash containers should be provided and conveniently located to maintain a neat, orderly appearance.

Playground Characteristics

1. The playground is the chief center of outdoor play for kindergarten and school age children from 5 to 12 years of age. It also offers some opportunities for recreation for young people and adults.

2. The playground at every elementary school should be of sufficient size and design, and properly maintained, to serve both the elementary educational program and the recreational needs of all age groups in the neighborhood. Since education and recreation programs complement each other in many ways, unnecessary duplication of essential outdoor recreational facilities should be avoided. Only where this joint function is not feasible should a separate playground be developed.

3. A playground may include (a) a playlot for preschool children, (b) an enclosed playground equipment area for elementary school children, (c) an open, turfed area for active games, (d) shaded areas for quiet activities, (e) a paved, multipurpose area, (f) an area for field games, and (g) circulation and buffer space.

Location of Playground

A playground is an integral part of a complete elementary school development. School playgrounds and other playgrounds should be readily accessible from and conveniently related to the housing area served. A playground should be within $\frac{1}{4}$ to $\frac{1}{2}$ mile of every family housing unit.

Size and Number of Playgrounds

Recommended size of a playground is a minimum of 6 to 8 acres, which would serve approximately 1,000 to 1,500 families. The smallest playground that will accommodate essential activity spaces is about 3 acres, serving approximately 250 families (about 110 elementary school children). This minimum area should be increased at the rate of 0.2 to 0.4 acres for each additional 50 families. More than one playground should be provided where (1) a complete school playground is not feasible, (2) the population to be served exceeds 1,500 families, or (3) the distance from the housing units is too great.

Playground Activity Spaces and Elements

A playground should contain the following basic activity spaces and elements:

1. A playlot, as described in the preceding section, with equipment and surfacing as recommended.

2. An enclosed playground equipment area with supplemental planting for elementary school children, and with equipment as recommended.

3. An open, turfed area for informal active games for elementary school children.

4. Shaded areas for quiet activities such as reading, storytelling, quiet games, handicrafts, picnicking and horseshoe pitching for both children and adults.

5. A paved and well-lighted, multipurpose

PLAYLOTS AND PLAYGROUNDS

area large enough for (a) activities such as roller skating, dancing, hopscotch, four square, and captain ball, and (b) games requiring specific courts, such as basketball, volleyball, tennis, handball, badminton, paddle tennis, and shuffleboard.

6. An area for field games, preferably well-lighted, (including softball, junior baseball, touch or flag football, soccer, track and field activities, and other games), which will also serve for informal play of field sports and kite flying, and be used occasionally for pageants, field days, and other community activities.

7. Miscellaneous elements such as public shelter, storage space, toilet facilities, drinking fountains, walks, benches, trash containers, and buffer zones with planting.

Layout of Playgrounds

The layout of a playground will vary according to size of available area, its topography, and the specific activities desired. It should fit the site with maximum preservation of the existing terrain and such natural site features as large shade trees, interesting ground forms, rock outcrops and streams. These features should be integrated into the layout to the maximum extent feasible for appropriate activity spaces, as natural divisions of various use areas, and for landscape interest. Grading should be kept to a minimum consistent with activity needs, adequate drainage and erosion control. General principles of layout are described as follows:

1. The playlot and the playground equipment area should be located adjacent to the school and to each other.

2. An open, turf area for informal active play should be located close to the playlot and the playground equipment area for convenient use by all elementary school children.

3. Areas for quiet activities for children and adults should be somewhat removed from active play spaces and should be close to tree-shaded areas and other natural features of the site.

4. The paved multipurpose area should be set off from other areas by planting and so located near the school gymnasium that it may be used for physical education without disturbing other school classes. All posts or net supports required on the courts should be constructed with sleeves and caps which will permit removal of the posts and their supports.

5. The area for field games should be located on fairly level, well-drained land with finished grades not in excess of 2.5 percent; a minimum grade of 1 percent is acceptable on pervious soils having good percolation for proper drainage.

6. In general, the area of a playground may be divided as follows: (a) Approximately half of the area should be parklike, including the open, turf areas for active play, the shaded areas for quiet activities, and the miscellaneous elements as described in 7 below; (b) the other half of the area should include $\frac{1}{4}$ to 1 acre for the playlot, playground equipment area, and the paved, multipurpose area, and $\frac{1}{4}$ to 1 acre (for softball) to 4 acres (for baseball) for the field games area.

7. The playground site should be fully developed with landscape planting for activity control and traffic control, and for attractiveness. This site also should have accessible public shelter, storage for maintenance and recreation equipment, toilet facilities, drinking fountains, walks wide enough for strollers and carriages, bicycle paths, benches for adults and children, and trash containers.

General Equipment Selection Factors

The following general factors should be considered in selecting equipment for playlots and playgrounds.

Developmental and Recreational Values All equipment should contribute to the healthy growth and recreational enjoyment of the child, so that he learns to coordinate, cooperate, compete, create, enjoy, and acquire confidence. Play equipment should:

1. Develop strength, agility, coordination, balance, and courage.
2. Stimulate the child to learn social skills of sharing and playing with others, and to compete in a spirit of fair play.
3. Encourage each child to be creative and have play experiences which are meaningful to him.
4. Permit the child to have fun and a sense of complete enjoyment.
5. Assist the child in making the transition from playlot to playground.

Child Preference and Capacity Play equipment, to be selected with due regard to the child's changing preference, maturity, and capacity, should:

1. Be scaled and proportioned to meet the child's physical and emotional capacities at different age levels.
2. Permit the child to do some things alone without direct adult supervision or assistance.
3. Provide a wide variety of play opportunities to accommodate changing interests of the child.
4. Free the child's imagination.
5. Meet a variety of interests, abilities, and aptitudes.

Safety of Participants All play equipment should be designed and built for safety of the participants, and:

1. Be free of all sharp protruding surfaces caused by welds, rivets, bolts, or joints.
2. Have sufficient structural strength to withstand the expected loads.
3. Be designed to discourage incorrect use and to minimize accidents; examples are seats that discourage children from standing in swings, slides that require children to sit down before sliding, and steps or ladders that discourage more than one participant at a time.
4. Have hand or safety rails on all steps and ladders, and nonskid treads on all steps.
5. Be installed in accordance with the specific directions of the manufacturer.
6. Be placed over suitable surfaces that will reduce the danger of injury or abrasions in the event a child falls from the climbing, moving or sliding equipment. (A safe landing surface should be provided at the end of a slide chute.)

Durability of Equipment Equipment that is durable should be selected. It should be made of materials which are of sufficient strength and quality to withstand normal play wear. Wood should be used only where metal or plastics have serious disadvantages. All metal parts should be galvanized or manufactured of corrosion-resistant metals. All movable bearings should be of an oilless type. Equipment should be designed as vandal-resistant as possible (for example, wire-reinforced seats for swings).

Equipment with Eye Appeal All play equipment should be designed and selected for function, for visual appeal to stimulate the child's imagination, with pleasing proportions and

with colors in harmonious contrast to each other and the surroundings. Play equipment may have a central theme, to reflect historical significance of the area, a storybook land, a nautical motif or a space flight motif. The theme may be carried out by constructing retaining or separation walls to resemble a corral, ship, or airplane, and by appropriate design of such elements as paving, benches, and trash cans.

Ease of Maintenance Equipment should be selected which requires a minimum of maintenance. Purchased equipment should be products of established manufacturers who can provide a standard parts list. Equipment parts which are subject to wear should be replaceable. Color should be impregnated into the material, if feasible, to avoid repainting. Sand areas should be surrounded by a retaining wall and be maintained regularly to remove foreign objects and loosen the sand as a suitable play medium.

Supervision Equipment should be selected that requires a minimum of direct supervision.

Basic Play Equipment

General Play equipment may include swings, slides, and merry-go-rounds; various types of climbers; balancing equipment such as balance beams, conduit, leaping posts, and boxes; hanging equipment such as parallel bars, horizontal bars, and ladders; play walls and playhouses; and a variety of play sculpture forms. Different types of play equipment should be provided for preschool children and for elementary school children to meet the developmental and recreational needs of the two age groups.

Playlot Equipment for Preschool Children The following table indicates types, quantities, and minimum play space requirements for various types of equipment totaling about 2,800 sq ft; this area, plus additional space for circulation and play space dividers, will accommodate a full range of playlot equipment serving a neighborhood containing approximately 50 preschool children (about 165 families).

Equipment	Number of pieces	Play space requirements, ft
Climber	1	10 x 25
Junior swing set (4 swings)	1	16 x 32
Play sculpture	1	10 x 10
Play wall or playhouse	1	15 x 15
Sand area	1	15 x 15
Slide	1	10 x 25
Spray pool (including deck)	1	36 x 36

Smaller playlots may be developed to serve a neighborhood containing some 30 children (about 100 families), using a limited selection of equipment with play space requirements totaling about 1,200 sq ft; this area, plus additional space for circulation and play space dividers, should consider the following desirable priorities: (1) a sand area; (2) a climbing device such as a climber, a play wall or a piece of play sculpture; (3) a slide, and (4) a swing set. Where several playlots are provided, the equipment selections should be complementary, rather than all being the same type. For example, one playlot may include play walls or a playhouse, while another playlot may provide a piece of play sculpture. Also, such a costly but popular item as a spray pool may be justified in only one out of every two or three playlots provided.

Playground Equipment for Elementary School Children
The following table indicates types, quantities, and minimum play space requirements totaling about 6,600 sq ft; this area, plus additional space for circulation, miscellaneous elements, and buffer zones, will accommodate a full range of playground equipment serving approximately 50 children at one time.

Equipment	Number of pieces	Play space requirements, ft
Balance beam	1	15 x 30
Climbers	3	21 x 50
Climbing poles	3	10 x 20
Horizontal bars	3	15 x 30
Horizontal ladder	1	15 x 30
Merry-go-round	1	40 x 40
Parallel bars	1	15 x 30
Senior swing set (6 swings)	1	30 x 45
Slide	1	12 x 35

Surfacing

General Selection of suitable surfacing materials for each type of play area and for circulation paths or walks, roads, and parking areas, should be based on the following considerations:

1. **Function** The surface should suit the purpose and the specific function of the area (such as surfaces for court games or field games, and surfaces under play equipment). The surface should also be considered from the basis of whether the area is multipurpose or single-purpose, and for seasonal or year-round usage.

2. **Economy** The factors of economy are the initial cost, replacement cost, and maintenance cost. Often an initially more expensive surfacing is the least expensive in the long run because of reduced maintenance.

3. **Durability** The durability of the surface should be evaluated in light of its resistance to the general wear caused by the participants, and resistance to extended periods of outdoor

weathering such as sunlight, rain, freezing, sand, and dust.

4. **Cleanliness** The surface should be clean and attractive to participants, it should not attract or harbor insects or rodents, and it should not track into adjacent buildings or cause discoloration to children's clothing.

5. **Maintenance** Maintenance must be evaluated not only in light of the cost, but also of the time when the facility is not available for use due to repair or upkeep.

6. **Safety** The safety of the participants is a primary consideration in selecting a play surface and should not be compromised for the sake of economy.

7. **Appearance** A surface which has an attractive appearance and harmonizes with its surroundings is very desirable. Surfacing materials should encourage optimum use and enjoyment by all participants, and channel the activities in an orderly manner by providing visual contrasts.

Evaluation of Surfacing Materials

1. **Turf** This material is generally considered to be the best surface for many of the recreation activities carried on at playlots and playgrounds. Although turf is not feasible for play areas having heavy participant use, most park and recreation authorities recommend using turf wherever practicable. Underground irrigation sprinkler systems with rubber top valves should be specified in areas with inadequate seasonal rainfall to maintain a turf cover. Major reasons for using turf are that it is relatively soft, providing greater safety than other surfaces, and it has a pleasing, restful appearance with great appeal to participants. A turf surface is especially suitable for open and informal play areas for younger children, and the large field game areas for sports and general recreation use.

2. **Bituminous Concrete** This flexible paving material is the most generally used

material for paving play areas. The designer should note that various asphalt grades and mixes are available, as well as color-coatings to improve appearance and maintenance. A suitable mix and careful grade control should be used to obtain a smooth, even surface, economical construction, and little or no maintenance. Bituminous concrete pavement is especially useful for paved, multipurpose areas, for tennis, basketball, and volleyball courts, roller skating and ice skating rinks, and for walks, roads, and parking areas.

3. **Portland Cement Concrete** This rigid paving material is the most favored type of surface for use in specialized areas where permanence is desired, and to provide uniformity, maximum durability, and little or no maintenance. A Portland cement concrete surface is especially useful for court games requiring a true, even surface, such as tennis and handball, for shuffleboard courts, roller skating and ice skating rinks, and for walks, curbs, roads, and parking areas.¹

4. **Synthetic Materials** Synthetic materials that have a cushioning effect are being used by some school, park and recreation departments, primarily for safety, under play equipment. Several companies have developed successful resilient materials which provide excellent safety surfaces; these have been more expensive than the other materials discussed.

5. **Miscellaneous Materials** Materials used for specific areas include sand, sawdust, tan-bark, or wood chips around and under play equipment, earth on baseball diamond infields, and brick, flagstone, or tile on walks and terraces.

¹NOTE: Portland cement concrete and bituminous concrete surfaces are generally considered for many of the same uses. Selection of either one should include appropriateness for the purpose intended, the initial cost, and long-term cost, at each location.

PLAYLOTS AND PLAYGROUNDS

AREAS & EQUIPMENT

Desirable standards for recreation facilities have been set up by the National Recreation Association and are generally recognized. Absolute standardization is impossible because of variable factors: climatic conditions; population or institutional needs, habits or preferences; and available land or money. Information on these pages may be used in planning and space allocation.

Basic general standard for public areas is 1 acre of open space per 100 total population, of which 40 to 50 per cent should be devoted to games or other active recreation. (See also recommendations in section on "Apartments.") No set formula has been established for institutions such as churches, schools, colleges. Local conditions, such as extent of participation in organized athletics, available money, etc., should govern the choice; however, playfields for elementary and grammar schools may follow schemes outlined below.

Game areas and layouts contained in the drawings are based on practice of the New York City Department of Parks. Where games are subject to official rules, consult publications of athletic organizations or other governing bodies.

Types of public recreational areas have been set up by the National Recreation Association, based on age groups and urban or suburban needs.

Surfacing of play areas influences utility, extent and cost of upkeep, and extent of playing season. Local materials, climate, soil, intensity of use and tradition influence choice of surfacing. In general all areas require effective surface or subsurface drainage or both.

THE PLAYLOT

Playlots are intended for children of preschool age and are commonly provided in densely populated areas as a substitute for backyard play. They are also provided in interiors of large blocks in neighborhood or housing developments, often for nursery schools.

Size may vary from 6,000 to 10,000 sq ft for each 100 preschool children.

Location should be centered among population served, and accessible without crossing traffic arteries. Interior of a block is ideal if one block only is served. If available space is limited, a corner of children's playground may be used.

Plan elements include: (1) central grass plot; (2) areas with shade trees, in which apparatus and benches are set; (3) hard-surfaced walkway for wheel toys, veloci-

Table 1. Playlots

Type of Equipment or Area	Area per Unit (Sq. Ft.)	Capacity in Children	Suggested Number Included
Apparatus			
Junglegym, Jr.	180	10	1
Low Slide	170	6	1-2
Low Swing	150	1	4-8
Low See-saw	100	2	4-8
Miscellaneous			
Open Space	48-50 per child	Varies with pop. to be served	
Block Bldg. Platform	20 per child 150 per platform	7-8 per platform	1
Sand Box	18-20 per child 300 per box	15	1-2
Benches & Tables	Optional	Varies

Flag Pole			1
Bird Bath	In open area		1
Drinking Fountain			1

* Sand boxes should be located so as to receive direct sunlight part of each day for reasons of sanitation.

pedes, etc.; (4) surrounding low fence or hedge. Distribution of area may vary with topography, apparatus included and child population served. Minimum recommendations of National Recreation Association are given in Table 1.

CHILDREN'S PLAYGROUNDS

These are intended for children 5 to 15 years old. A subdivision of this type, characterized by smaller area and fewer facilities, is called the *Junior* or *Primary* Playground, and is intended for children up to 10 or 11 years.

Size of children's playgrounds ranges from 3 acres (minimum) to 7 acres. General recommendation is 1 acre per 1,000 total population. Two small playgrounds are usually more satisfactory than one of excessive size when population served requires a large acreage.

Location is usually in an area developed for this particular use, adjoining a grade school, in a neighborhood or large park, or a portion of a neighborhood playfield. Maximum radius of area to be served should preferably not exceed one-half mile; in areas of dense population or subject to heavy traffic, one-quarter mile.

Plan elements may be subdivided into apparatus section, specialized sports area, landscaping, and miscellaneous activities. Areas required are given in Table 2. Selection and distribution of areas and equip-

(a) Minimum desirable.

(b) One or all of these units may be omitted if playground is not used in conjunction with a school.

(c) May be omitted if sanitary facilities are supplied elsewhere.

(d) May be omitted if space is limited.

ment should be based on local preference, space and money available, and topography. Guides to selection of individual game areas or equipment are included in the footnotes to Table 2 where practicable.

In addition to the usual playground equipment listed on this page, some special equipment intended to stimulate imaginative play is now widely used. The examples following were pioneering efforts in this field, developed by the New York City Housing Authority in the late 1940's. A play boat and a play airplane, included in the original line of equipment, proved to be too expensive and too hazardous and are no longer used. A wide variety of imaginative playground equipment has been developed in recent years and is available from several commercial sources.

BADMINTON

ISOMETRIC SHOWING NET

Fig. 1 Badminton court. All measurements for court markings are to the outside of lines except for those involving the center service line which is equally divided between right and left service courts. All court markings to be 1½" wide and preferably white or in color. Minimum distance between sides of parallel courts to be 5'-0". For net post details see Fig. 51. For surfacing details see Figs. 58 to 61.

Recommended Area Ground space is 1620 sq ft minimum to edge of pavement.

Size and Dimension Singles court is 17' × 44', doubles court is 20' × 44' with a 5'-0" minimum unobstructed area on all sides.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating for permanent installation. Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft.

Badminton may be played on a turf court for general recreation use, with surface drainage as described above at a minimum slope of 2% and adequate underdrainage.

COURT LAYOUT

Material on pp. 1064-1117 from *Outdoor Sports Facilities*, Departments of the Army, Navy, and Air Force, Washington, D.C., 1975.

Fig. 2 AAU basketball court. All dimensions are to inside edge of lines except as noted. All lines to be .05 m (2") wide. Backboard shall be of any rigid weather-resistant material. The front shall be flat and painted white unless it is transparent. If the backboard is transparent, it shall be marked with a .05-m-wide white line around the border and a .45 × .59-m target area bounded with a .05-m-wide white line.

Recommended Area Ground space is 448 m² minimum to 540 m² recommended, including clear space.

Size and Dimension Playing court is 14×26 m with an unobstructed space of 1 m minimum to 2 m recommended on all sides.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating. Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 0.02 m in 3.05 m (1 m. in 10 ft.). See Figs. 59 and 61.

Special Considerations Safety—Backboard is to be 1.65 m from support post. Post may be padded.

BASKETBALL (NCAA)

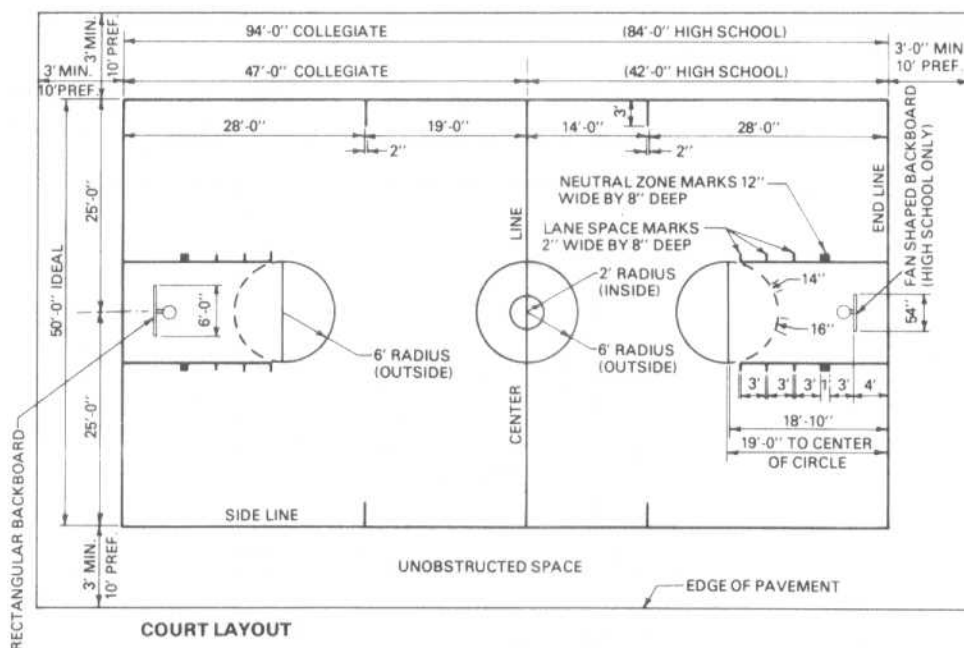

Fig. 3 NCAA basketball. The color of the lane space marks and neutral zone marks shall contrast with the color of the bounding lines. The midcourt marks shall be the same color as the bounding lines. All lines shall be 2 in wide (neutral zone excluded). All dimensions are to inside edge of lines except as noted. Backboard shall be of any rigid weather-resistant material. The front surface shall be flat and painted white unless it is transparent. If the backboard is transparent, it shall be marked with a 3-in wide white line around the border and an 18 × 24-in target area. If the backboard is transparent, it shall be marked with a 3-in wide white line around the border and an 18 × 24-in target area bounded with a 2-in wide white line.

Recommended Area *High School:* ground space is 5040 sq ft minimum to 7280 sq ft maximum. *Collegiate:* ground space is 5600 sq ft minimum to 7980 sq ft maximum.

Size and Dimension High school recommended court is 84 × 50 ft with a 10-ft unobstructed space on all sides (3 ft minimum). Collegiate recommended court is 94 × 50 ft with a 10-ft unobstructed space on all sides (3 ft minimum).

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating. (See Figs. 59 and 61.) Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft.

Special Considerations *Safety*—Backboard and goal support should have a minimum 32-in overhang and post may be padded if desired. Bottom edge and lower sides of rectangular backboard must be padded.

BIDDY BASKETBALL**COURT LAYOUT**

Fig. 4 Biddy basketball. All dimensions are to inside edge of lines except as noted. All lines shall be 2 in wide. For surfacing details see Figs. 59 and 61.

Recommended Area Ground space is 2,400 to 3,036 sq ft, including clear space.

Size and Dimension Playing court is 46'-0" to 50'-0" wide and 84'-0" long with an unobstructed space of at least 3 ft recommended on all sides.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating. Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft.

Special Considerations Safety—Backboard support standard is to be a minimum of 2 ft, preferably 4 ft, outside of the court area. Post may be padded.

GOAL-HI BASKETBALL

Fig. 5 Goal-Hi basketball. All court markings to be 2 in wide. For surfacing details see Figs. 59 and 61. Goal-Hi standard may be permanently mounted, removable flush mounted, or portable as shown.

Recommended Area Ground space minimum is 1256 sq ft; maximum is 2827 sq ft.

Size and Dimension Playing court is to be an Outer Court circle with a minimum radius of 20'-0" and a maximum radius of 30'-0", surrounding an Inner Court circle with a minimum radius of 10'-0" and a maximum radius of 15'-0".

Orientation Optional.

Surface and Drainage Concrete or bituminous surface may be used for minimum maintenance, but a resilient synthetic surface is preferred for safety and comfort. Minimum slope is 1 in. in 10 ft for drainage in any direction.

BOCCIE BALL

COURT LAYOUT

Fig. 6 Bocce. Court markings to be 2-in wide linen tape held in place with metal pins. For surfacing details see Figs. 58 and 60.

Recommended Area Ground space is 1,824 to 2,816 sq ft.

Size and Dimension Overall court dimensions are 13'-0" to 19'-6" wide by 78'-0" to 92'-0" long. Additional space of at least 3'-0" on each side and 9'-0" on each end is recommended.

Orientation Preferred orientation is for the long axis to be north-south although it is of minor importance.

Surface and Drainage Surface is to be preferably turf, although a mixture of sand and clay may be used. Drainage may be in any direction at a recommended slope of 1 percent for turf and level for sand-clay with underdrainage.

Special Considerations Optional low wooden barrier should be provided at each end and/or side of court.

Orientation Orientation is not critical and may be adjusted to suit local topographic conditions.

1070

THREE- AND FOUR-WALL HANDBALL

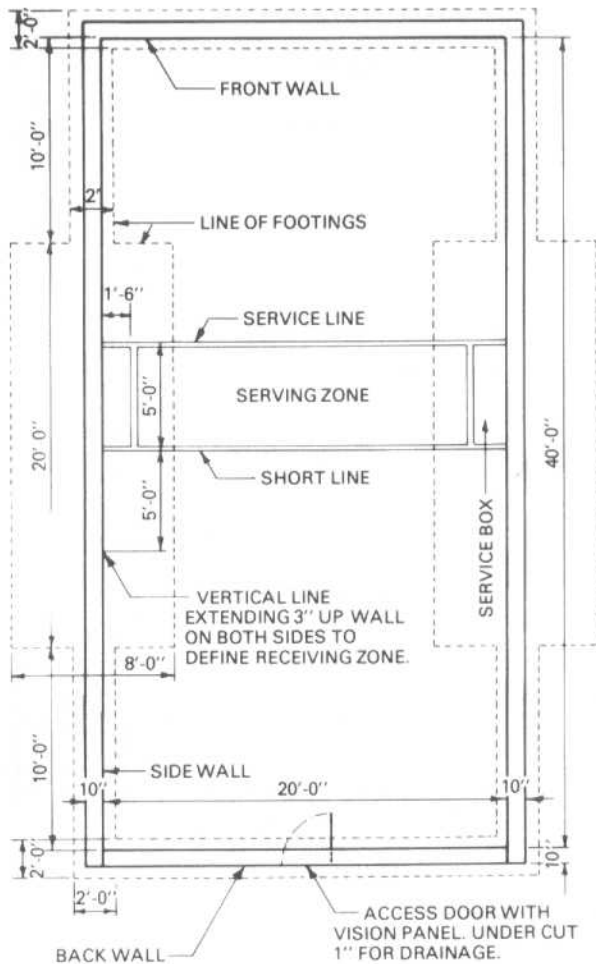

Fig. 9 Handball court layout—Four-wall. All court markings to be 1½ in wide and painted white, red, or yellow. For surfacing details see Fig. 59.

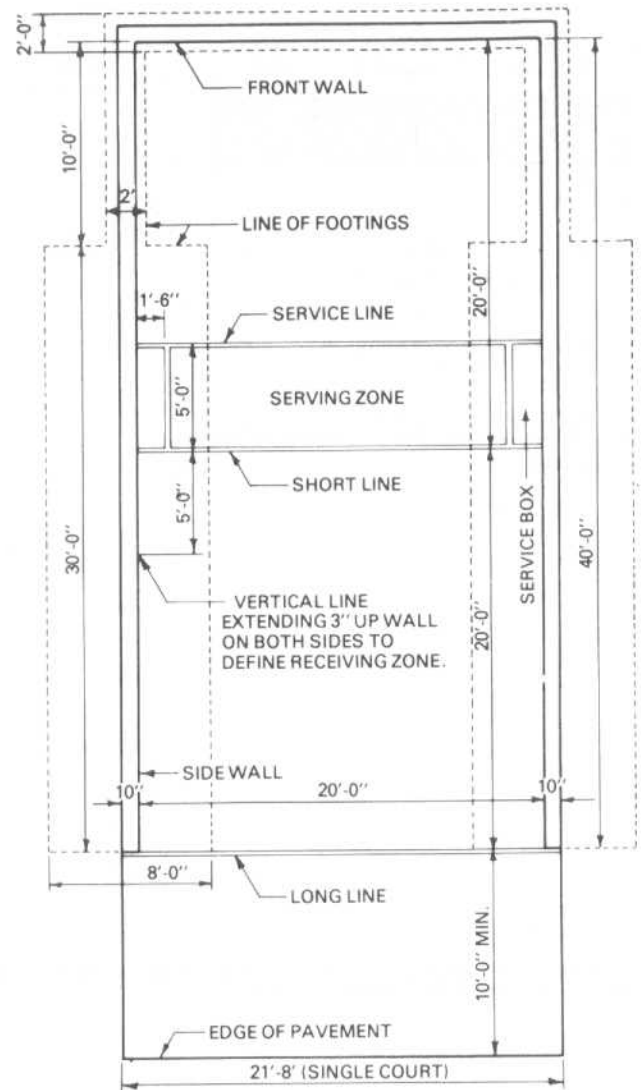

Fig. 10 Handball court layout—Three-wall. All court markings to be 1½ in wide and painted white, red, or yellow. For surfacing details see Fig. 59.

Recommended Area Ground space for four-wall handball is 800 sq ft, plus walls and footing. Allow an additional 200 sq ft for three-wall handball.

Size and Dimension Playing court is 20'-0" wide by 40'-0" long plus a minimum 10'-0" to the rear of the three-wall court. Overhead clearance required is 20'-0" minimum.

Orientation Preferred orientation is for the long axis to be north-south with the front wall at north end.

Surface and Drainage Surface is to be smooth concrete preferably with a minimum slope of 1 in. in 10 ft from front to rear of the court.

Special Considerations Alternate four-wall court—Layout is the same as for three-wall with the exception of a minimum 12'-0" high back wall at the rear of the court (long line) and necessary wall footings. Special provisions for drainage must be made and access provided through the back wall for four-wall courts. Fencing—An optional 10-ft-high chain link fence may be provided at the rear of the pavement for three-wall courts.

HOPSCOTCH

Fig. 11 Hopscotch court layout. All lines to be 1½ in wide painted with white or black acrylic paint to contrast with court surface. For surfacing details see Fig. 61.

Recommended Area Ground space is 62.5 sq ft.

Size and Dimension Playing court is 5'-0" wide by 12'-6" long.

Orientation Optional.

Surface and Drainage Surface is to be concrete or bituminous material with a lateral slope of 1 in. in 10 ft and a longitudinal slope of 1 in. in 10 ft minimum.

HORSESHOES

Fig. 12 Horseshoe pitching court.

Recommended Area Ground space is 1,400 sq ft, including clear space.

Size and Dimension Playing court is 10'-0" x 50'-0" plus a recommended 10-ft minimum unobstructed area on each end and a 5-ft (minimum) wide zone on each side.

Orientation Recommended orientation is for the long axis to be north-south.

Surface and Drainage Surface of playing area, except for boxes and optional concrete walkways, should be turf. Area should be pitched to the side at a maximum slope of 2 percent. Elevation and slant of steel pegs should be between 2 and 3 in and equal.

Special Considerations Boxes are to be filled with gummy potter's or blue clay. Safety—A 2'-0"-high backstop should be constructed at the end of the box to intercept overthrown or bounding shoes.

ICE HOCKEY

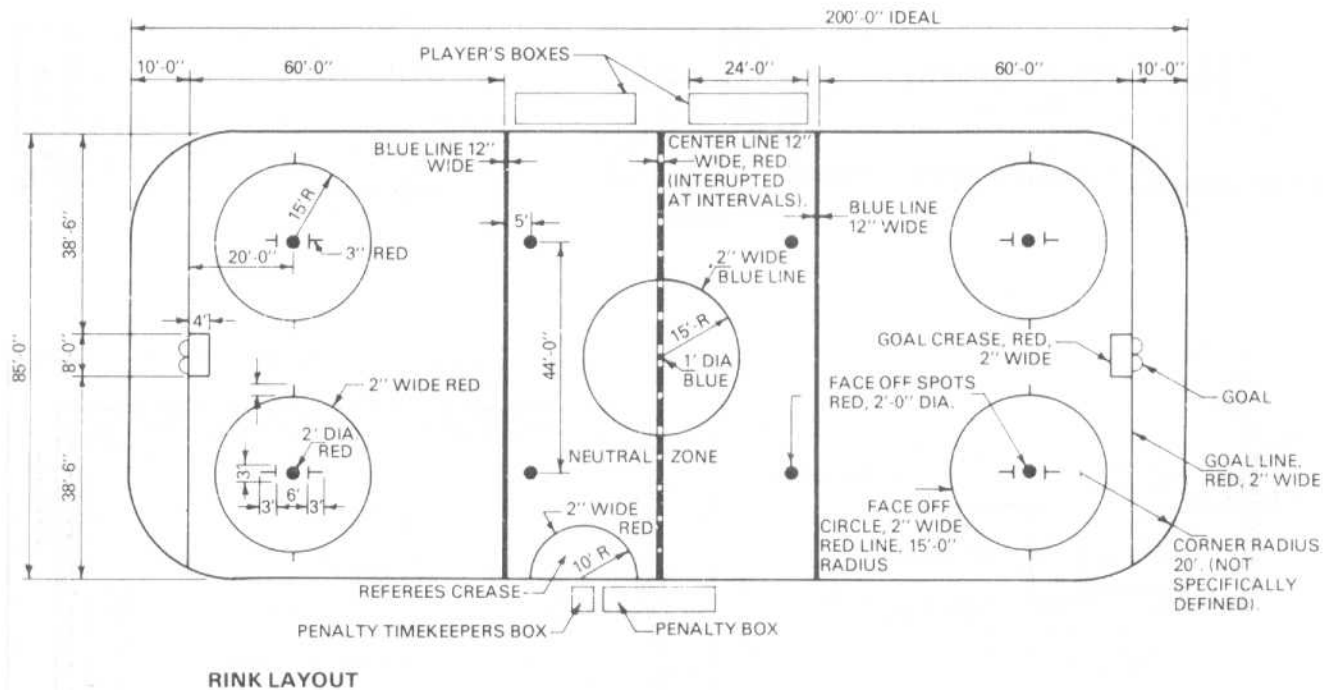

Fig. 13 Ice hockey rink. The rink shall be surrounded by a wooden wall or fence known as the "boards" which shall extend not less than 40 in nor more than 48 in above the level of the ice surface. Ideal 42 in. The surface of the boards facing the ice shall be smooth and free from obstructions. All access doors to the playing surface must swing away from the ice surface. A protective screening of heavy-gauge wire or safety glass is recommended above the boards, except for the bench areas, for the protection of spectators around the rink. The centerline and the two blue lines shall extend across the rink and vertically to the top of the boards. Surface to be flooded may be sand-clay or bituminous material (see Fig. 60 or 61).

Recommended Area Ground space is 22,000 sq ft, including support area.

Size and Dimension Playing rink is 85'-0" wide by 200'-0" (minimum 185'-0") long, plus an additional 5,000 sq ft of support area.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage The ice surface should be level over either sand-clay or bituminous surface. Provisions for drainage should be made on the surface beneath the ice and around the rink.

Special Considerations Ice—Unless situated in northern climates, provisions for artificial ice will be required.

LAWN BOWLING

Fig. 14 Lawn bowling green. Side boundaries of rinks to be marked with a 2-in-wide green linen tape attached with pins. The four corners of the rinks shall be indicated by pins driven flush with the face of the bank on each end. Centerline of each rink shall be marked by a pin or number panel. For surfacing details see Fig. 58 or 60.

Recommended Area Square green with six rinks is 12,996 sq ft minimum to 17,424 sq ft maximum.

Size and Dimension Square green is 110 ft minimum and 125 ft maximum on each side. Additional width of 2'-0" minimum to 3'-6" maximum is required on front, rear, and sides for ditch and backslope. Rink width minimum is 14'-0", maximum 19'-0". Rink length minimum is 110'-0", maximum 125'-0".

Orientation Optional.

Surface and Drainage Surface should be of closely cropped bent grass or sand-clay. Entire green should be level, with adequate underdrainage.

Special Considerations Ditch—Depth minimum 2 in, maximum 8 in below surface of green. Width minimum 8 in, maximum 15 in.

Fig. 15 Roque court. Boundary lines are marked by a light depression in playing surface without raising adjacent soil. Arches are 5/8-in dia. steel rod, 3-3/8 in wide and 8 in above the surface and set in 8 in \times 15 in \times 6 in concrete anchors. Stakes are 3/4-in dia. steel, set rigidly in the ground and extending 2 in above the surface. Playing surface should be hard, smooth and level sand-clay (see Fig. 60).

Recommended Area Ground space is 1,800 sq ft minimum, plus curb.

Size and Dimension Playing court is 30'-0" wide by 60'-0" long.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be level and sand-clay mixture. Drainage is to be through perimeter system and/or through underdrains.

Special Considerations Concrete curb is to be provided on all sides.

SHUFFLEBOARD

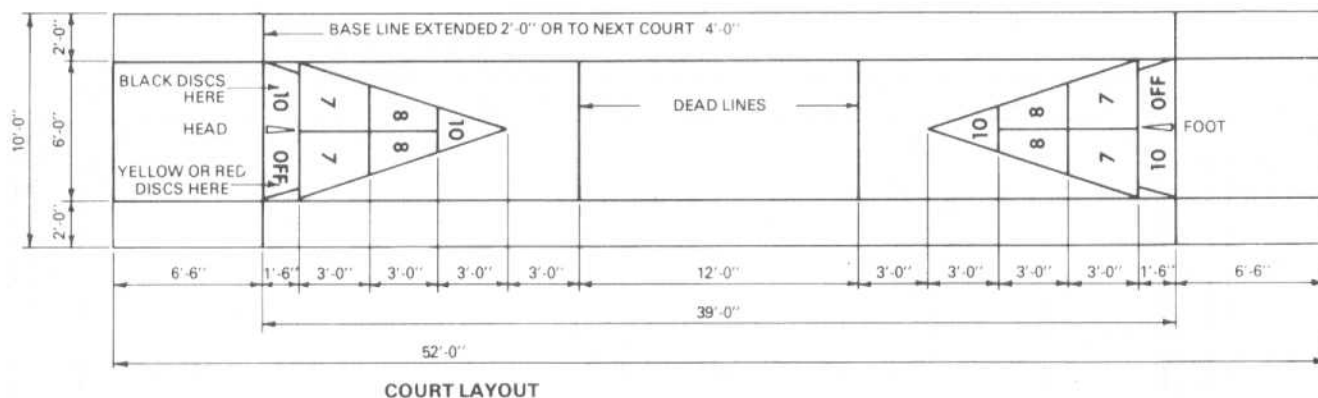

Fig. 16 Shuffleboard court. All dimensions are to centers of lines and to edge of court. Maximum line width $1\frac{1}{2}$ in, minimum $\frac{3}{4}$ in. Lines and Figures "10," "8," "7," and "10 OFF" should be marked with black shoe dye or black acrylic paint. Court to be constructed of concrete without expansion joints. A depressed alley at least 24 in wide, and not less than 4 in deep at midcourt, should be constructed between courts and on the outside of end courts. The alley should slope 1 in. in the first 6 ft of the length of the alley from each baseline, then slope to a minimum depth of 4 in at midcourt where a suitable water drain should be provided.

Recommended Area Ground space is 312 sq ft minimum.

Size and Dimension Playing court is 6'-0" \times 52'-0" plus a recommended minimum of 2'-0" on each side or 4'-0" between courts in battery.

Orientation Recommended orientation is for the long axis to be north-south.

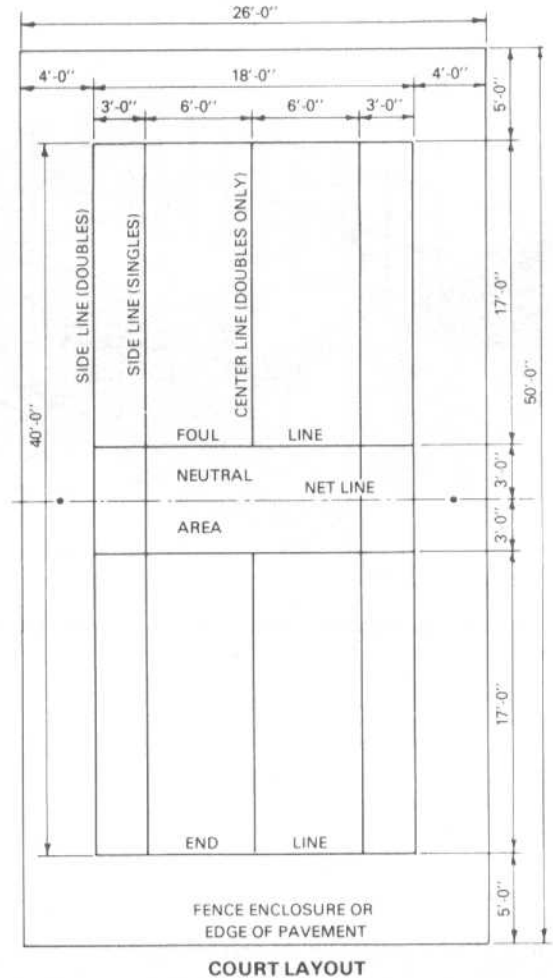

Surface and Drainage Surface is to be concrete with a burnished finish. Court surface is to be level with drainage away from the playing surface on all sides.

Special Considerations Secure covered storage for playing equipment should be provided near the court area.

DECK TENNIS

ISOMETRIC SHOWING NET

COURT LAYOUT

Fig. 17 Deck tennis court. All measurements for court markings are to the outside of lines except for those involving the center service line, which is equally divided between right and left service court. All court markings to be $1\frac{1}{2}$ in wide. Fence enclosure, if provided, should be $1\frac{1}{2}$ -in mesh, 11 gauge chain link. For fence details, see Fig. 55. For net post details see Fig. 51 or 52. For surfacing details see Fig. 59 or 61.

Recommended Area Ground space is 1300 sq ft including clear space.

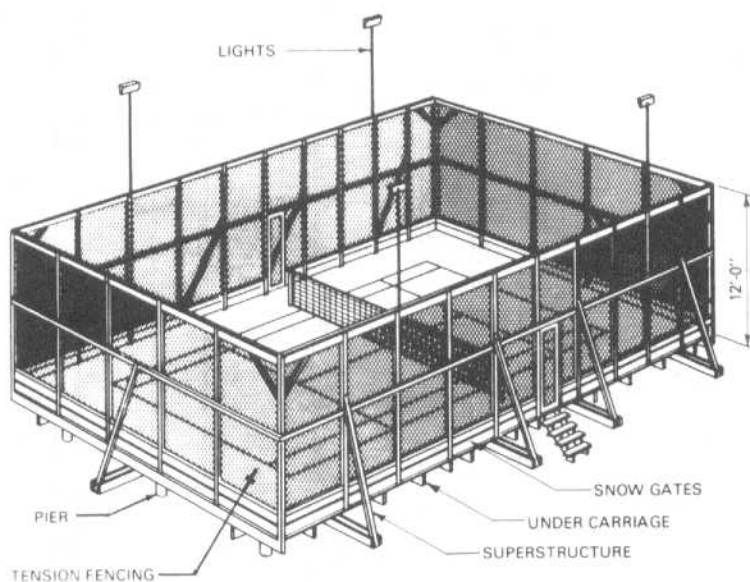

Size and Dimension Singles court is 12'-0" by 40'-0". Doubles court is 18'-0" by 40'-0". Additional paved area at least 4'-0" on sides and 5'-0" on ends is recommended.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating. Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft.

Special Considerations Fencing—10-ft-high chain link fence is recommended on all sides of the court.

PLATFORM TENNIS

ISOMETRIC SHOWING FENCE (TYPICAL WOOD CONSTRUCTION)

Fig. 18 Platform tennis court. All measurements for court markings are to the outside of lines except for those involving the center service line, which is equally divided between right and left service court. All court markings to be 2 in wide. Fencing required—12'-0" high with 16-gauge hexagonal, galvanized 1-in flat wire mesh fabric. For net post details see manufacturers' literature. Net height to be 3'-1" at posts and 2'-10" at center court.

Recommended area Ground space is 1,800 sq ft to the playable perimeter fence.

Size and Dimension Playing court is 20'-0" × 44'-0" plus an 8'-0" space on each end and a 5'-0" space on each side.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Raised level platform is normally constructed of treated wood or aluminum superstructure with carriage set on concrete piers to permit construction on slopes. Drainage

is provided by ¼-in space between 6-in deck planks or channels. Snow removal is facilitated by hinged panels (snow gates) between posts around bottom of perimeter fence.

Special Considerations Tension fencing—12-ft high, 16-gauge, hexagonal, galvanized, 1-in flat wire mesh fabric must be provided on all sides of the court. Lights should be provided, since this game is played at night throughout the year. Heating units with fans under the platform are used in cold climates. Prefabricated courts are available from several manufacturers.

PADDLE TENNIS

ISOMETRIC SHOWING NET

COURT LAYOUT

Fig. 19 Paddle tennis court. All measurements for court markings are to the outside of lines except for those involving the center service line, which is equally divided between right and left service court. All court markings to be $1\frac{1}{2}$ in wide. Fence enclosure, if provided, should be $1\frac{1}{2}$ in mesh, 11-gauge chain link. For fence details see Fig. 55. For net post details see Fig. 51. For surfacing details see Fig. 59 or 61.

Recommended Area Ground space is 3,200 sq ft minimum to edge of pavement.

Size and Dimension Playing court is 20'-0" \times 50'-0" plus a 15-ft minimum space on each end and a 10-ft minimum space on each side or between courts in battery.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Surface is to be concrete or bituminous material with optional protective colorcoating. Drainage is to be end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft.

Special Considerations Fencing—10-ft-high chain link fence is recommended on all sides of the court.

TENNIS

Fig. 20 Tennis court. All measurements for court markings are to the outside of lines except for those involving the center service line which is equally divided between the right and left service courts. All court markings to be 2 in wide. Fence enclosure, if provided, should be 10-ft-high, 11-gauge, $1\frac{3}{4}$ in mesh chain link. For fence details see Fig. 55. Minimum distance between sides of parallel courts to be 12'-0". For net post details see Fig. 52. For surfacing details see Fig. 59, 60, or 61.

Recommended Area Ground space is 7,200 sq ft minimum.

Size and Dimension Playing court is 36×78 ft plus at least 12 ft clearance on both sides or between courts in battery and 21 ft clearance on each end.

Orientation Orientation of long axis is to be north-south.

Surface and Drainage Surface may be concrete, or bituminous material with specialized protective colorcoating, or sand-clay. Drainage may be from end to end, side to side, or corner to corner diagonally at a minimum slope of 1 in. in 10 ft for pavement and level for sand-clay with under-drainage.

Special Considerations Fencing—Recommended 10-ft-high chain link fence on all sides.

TETHER BALL

Fig. 21 Tetherball court. All measurements for court markings are to center of lines. All court markings to be 2 in wide. If colorcoating is used, the neutral zones and the playing zones should be of contrasting colors. For surfacing details see Fig. 59 or 61.

Recommended Area Ground space is 314 sq ft minimum to circumference of outer circle.

Size and Dimension Playing court is a circle 20'-0" in diameter. Pole height is 10 ft.

Orientation Recommended axis through playing zone is north-south.

Surface and Drainage Concrete or bituminous surface may be used for minimum maintenance, but a resilient synthetic surface or wood chips with adequate underdrainage is preferred for safety and comfort. Minimum slope is 1 in. in 10 ft for drainage in any direction.

VOLLEYBALL

Fig. 22 Volleyball court. All measurements for court markings are to the outside of lines except for the centerline. All court markings to be 2 in wide except as noted. For surfacing details see Figs. 58 to 61. Net height at center to be: men 8'-0", women 7'-4 1/4", high school 7'-0", elementary school 6'-6". For net and post details see Fig. 53.

Recommended Area Ground space is 4000 sq ft.

Size and Dimension Playing court is 30 × 60 ft plus 6 ft minimum, 10 ft preferred, unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be north-south.

Surface and Drainage Recommended surface for intensive use is to be bituminous material or concrete, but sand-clay or turf may be used for informal play. Drainage is to be end to end, side to side or corner to corner at a minimum slope of 1 in. in 10 ft.

OFFICIAL BASEBALL

Babe Ruth Baseball (13-15 yr and 16-18 yr); Senior League Baseball (13-15 yr)

LAYOUT AT HOME PLATE

LAYOUT AT PITCHER'S PLATE

DIAMOND LAYOUT

Fig. 23 Official baseball diamond. Foul lines, catcher's, batter's, and coach's boxes, next batter's circles, and 3-ft line shall be 2 to 3 in wide and marked with chalk or other white material. Caustic lime must not be used. Infield may be skinned. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58. For backstop details see Fig. 62.

Recommended Area Ground space is 3.0 to 3.85 acres minimum.

Size and Dimension Baselines are 90'-0". Pitching distance is 60'-6". Pitcher's plate is 10 in above the level of home plate. Distance down foul lines is 320 ft minimum, 350 ft preferred. Outfield distance to center field is 400 ft +. For Senior League Baseball, recommended distance from home plate to outfield fence at all points is 300 ft +.

Orientation Optimum orientation is to locate home plate so that the pitcher is throwing across

the sun and the batter is not facing it. The line from home plate through the pitcher's mound and second base should run east-northeast.

Surface and Drainage Surface is to be turf. Infield may be skinned, and shall be graded so that the baselines and home plate are level.

Special Considerations Backstop is to be provided at a minimum distance of 40 ft or preferably 60 ft behind home plate.

Special Considerations Backstop is to be provided at a recommended distance of 20 ft behind home plate.

Special Considerations Backstop is to be provided at a recommended distance of 40 ft behind home plate.

Special Considerations Backstop is to be provided at a recommended distance of 60 ft behind home plate.

BASEBALL

Little League (9-12 yr)

LAYOUT AT HOME PLATE

Fig. 27 Little league baseball diamond. Foul lines, catcher's, batter's, and coach's boxes, next batter's circles, and 3-ft restraining lines shall be 2 in wide and marked with white chalk or other white material. Caustic lime must not be used. Infield may be skinned. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58. For backstop details see Fig. 62.

Recommended Area Ground space is 1.2 acres minimum.

Size and Dimension Baselines are 60'-0". Pitching distance is 46'-0". Pitcher's plate is 6 in above the level of home plate. Distance down foul line is 200 ft. Outfield distance to pocket in center field is 200 to 250 ft optional.

Orientation Optimum orientation is to locate home plate so that the pitcher is throwing across

the sun and the batter is not facing it. The line from home plate through the pitcher's mound and second base should run east-northeast.

Surface and Drainage Surface is to be turf. Infield may be skinned, and shall be graded so that the baselines and home plate are level.

Special Considerations Backstop is to be provided at a recommended minimum distance of 25 ft behind home plate.

FIELD HOCKEY

Fig. 28 Field hockey playing field. All measurements shall be made from the inside edge of lines marking boundaries. Solid and broken lines shall be white, 3 in wide and marked with a nontoxic material which is not injurious to the eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 64,000 sq ft (1.5 acres) minimum.

Size and Dimension Playing field width is 180'-0". Length is 300'-0". Additional area recommended is 10'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal is to be provided at each end of the playing field.

Fig. 29 Flickerball field. All measurements should be made from the inside edge of lines marking boundaries. Lines shall be white and 3 in wide and marked with a nontoxic material which is not injurious to the eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 17,600 sq ft (0.4 acre) minimum.

Size and Dimension Playing field width is 90'-0". Length is 160'-0". Goals are 15'-0" beyond each end line. Additional area recommended is 6'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal is to be provided 15'-0" behind each end line.

Fig. 31 Touch and flag football field. Optional goal post may be used in the form of a single metal post set behind the end zone with a cantilevered horizontal crossbar and two uprights of the same height and spacing as for dual posts. Pylon to be constructed of soft flexible material, red or orange in color. All measurements should be made from the inside edge of lines marking boundaries. All field dimension lines shown must be marked 4 in. in width with a white, nontoxic material which is not injurious to the eyes or skin. If cross hatching in end zone is white, it shall be no closer than 2 ft to the boundary lines. When teams are composed of 9 or 11 players, a field 360'-0" (120-yd.) long with five 60'-0" (20-yd) zones and two 30'-0" (10-yd) end zones is recommended. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 41,200 sq ft (0.94 acre) minimum.

Size and Dimension Playing field width is 120'-0". Length is 300'-0". Additional area recommended is 6'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal posts are to be provided at each end of the playing field. Pylons are to be provided as required by rules.

GOLF DRIVING RANGE

Fig. 32 Driving range.

Recommended Area Ground space for minimum of 25 tees is 13.5 acres.

Size and Dimension Minimum length is 900 ft (300 yd). Minimum width, including buffer area on each side, is 690 ft (230 yd). Add 12 ft width per additional tee.

Orientation Preferred orientation is for the long axis to run southwest to northeast with the golfer driving toward the northeast.

Surface and Drainage Surface is to be turf closely mowed in center for ball collection. Side buffer areas are to be rough cut. Drainage is to be away from raised tee area and preferably across the axis of play. Side buffer areas may rise to help contain stray drives.

LACROSSE

Men's

PLAYING FIELD LAYOUT

DETAIL OF GOAL

FLAG DETAIL

Fig. 33 Playing field for men's lacrosse. Goal net should be cord netting with openings of not more than 1½ in. Bottom of net must be held close to the ground with pegs or staples. Posts to be 1½-in nominal pipe painted orange and secured to the ground. Lines must be marked with a white nontoxic material which is not injurious to the eyes or skin. All lines shall be 2 in wide except the center or offside line which should be 4 in wide. All dimensions are to inside of lines except at centerline. Barrier fence, 5 or 6 ft high, should be 10'-0" minimum from end and side lines. If not used allow 20-ft space on all sides. Flexible flag markers shall be placed at the four corners of the field and at each end of the centerline. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 62,650 sq ft (1.4 acres) to 70,000 sq ft (1.6 acres).

Size and Dimension Playing field width is 159'-0" to 180'-0". Length is 330'-0". Additional area recommended is 10'-0" minimum unobstructed space around entire perimeter of field with barrier fence, or 20'-0" without fence.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle

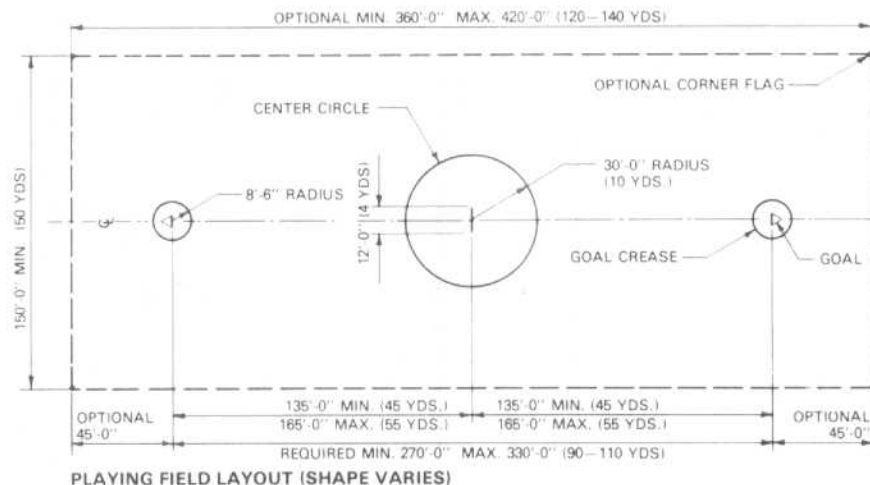

of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal is to be provided 45'-0" in front of each end line.

LACROSSE

Women's

OPTIONAL FLAG DETAIL

DETAIL OF GOAL

Fig. 34 Playing field for women's lacrosse. Goal net should be cord netting with openings of not more than 1½ in. Bottom of net must be held close to the ground with pegs or staples. Posts and crossbar shall be of wood, 2 × 2 in and shall be painted white. Goals made of pipe and painted white are considered legal but wooden goals, 2 × 2 in, are preferred. All marking lines shall be 2 in wide and marked with a white nontoxic material which is not injurious to the eyes or skin. Boundary lines are optional but should be 2 in wide if marked. Optional flag may be placed at the four corners or selected boundary points. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is optional 54,000 sq ft (1.2 acres) to 61,500 sq ft (1.4 acres).

Size and Dimension Playing field minimum width is 150'-0". Optional length is 360'-0" to 410'-0". As in the original Indian game, there are no definite boundaries or shape for the field of play, but before a match the officials decide on the boundaries and declare specified obstructions out of bounds.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle

of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side with adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal is to be provided 45'-0" in front of each end line.

SOCCER

Men's and Boys'

Fig. 35 Playing field for men's and boys' soccer. Goal posts to be pressure treated with paintable, oil-borne preservative and painted above ground with three coats of white lead and oil. The goalposts and crossbar shall present a flat surface to the playing field, not less than 4 in nor more than 5 in. in width. Nets shall be attached to the posts, crossbar, and ground behind the goal. The top of the net must extend backward 2'-0" level with the crossbar. All dimensions are to the inside edge of lines. All lines shall be 2 in wide and marked with a white, nontoxic material which is not injurious to the eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 75,250 sq ft (1.7 acres) to 93,100 sq ft (2.1 acres).

Size and Dimension Playing field width is 195'-0" to 225'-0". Length is 330'-0" to 360'-0". Additional area recommended is 10'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal posts are to be provided at each end of the playing field.

SOCCER

Women's and Girls'

PLAYING FIELD LAYOUT

GOAL POSTS

Fig. 36 Playing field for women's and girls' soccer. Goal posts to be pressure treated with painted, oil-borne preservative and painted above ground with three coats of white lead and oil. The goal posts and crossbar shall present a flat surface to the playing field, not less than 4 in nor more than 5 in. in width. Nets shall be attached to the posts, crossbar, and ground behind the goal. The top of the net must extend backward 2'-0" level with the crossbar. All dimensions are to the inside edge of lines. All lines shall be 2 in wide and marked with a white, nontoxic material which is not injurious to the eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 36,400 sq ft (0.8 acre) to 64,000 sq ft (1.4 acres).

Size and Dimension Playing field width is 120'-0" to 180'-0". Length is 240'-0" to 300'-0". Additional area recommended is 10'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal posts are to be provided at each end of the playing field.

Special Considerations Backstop is to be located at a minimum distance of 25 ft behind home plate.

SOFTBALL, 16-INCH

Slow Pitch

LAYOUT AT HOME PLATE

Fig. 38 Diamond for 16-in softball. Foul lines, catcher's, batter's, and coach's boxes, and 3-ft lines are 2 to 3-in chalk lines. Baselines for women to be 50'-0". Pitching distance does not change. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58. For backstop details see Fig. 63.

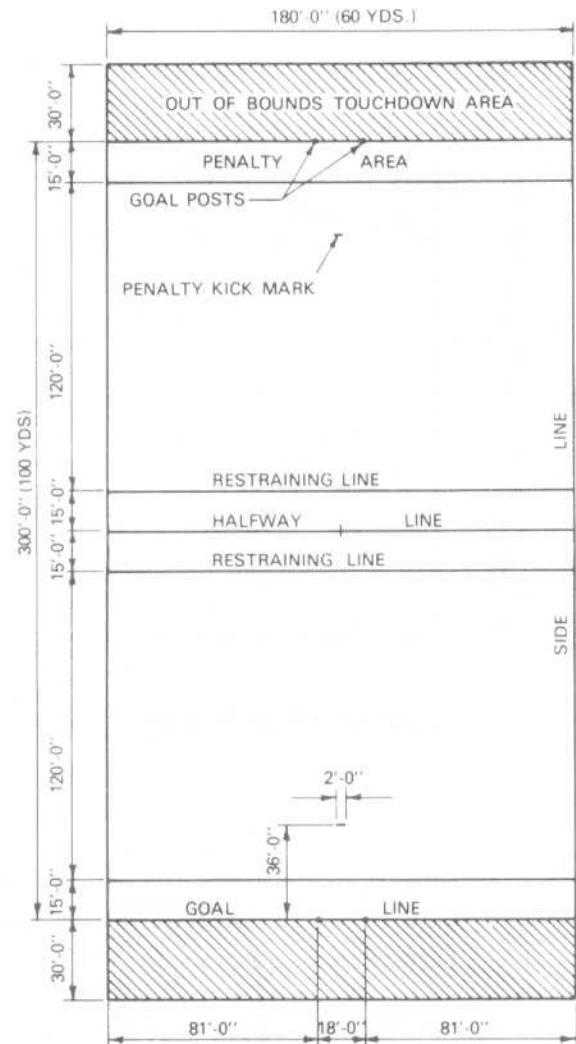

Recommended Area Ground space is 50,625 sq ft (1.2 acres) to 75,625 sq ft (1.7 acres).

Size and Dimension Baselines are 55'-0" for men, 50'-0" for women. Pitching distance is 38'-0" for men and women. Playing field radius from home plate between foul lines is 250 ft for men, 200 ft for women.

Orientation Optimum orientation is to locate home plate so that the pitcher is throwing across the sun and the batter is not facing it.

Surface and Drainage Surface is to be turf. Infield may be skinned. The infield shall be graded so that the baselines and home plate are level.

Special Considerations Backstop is to be located at a minimum distance of 25 ft behind home plate.

PLAYING FIELD LAYOUT

Fig. 39 Speedball field. All dimensions are to inside edge of lines. All field markings to be 2 in wide and marked with a white nontoxic material which is not injurious to the eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 36,400 sq ft (.85 acre) (high school) to 76,000 sq ft (1.7 acres).

Size and Dimension Playing field width is 180'-0". Length is 300'-0". An additional 30 × 180-ft out-of-bounds touchdown area is recommended on each end and unobstructed space of 10'-0" on all sides. High school field may be 120 ft wide by 240 ft long.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle

of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and adequate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal posts are to be provided at each end of the playing field.

PLAYING FIELD LAYOUT

GOAL POSTS AND CROSSBAR

Fig. 40 Playing field for team handball. Team handball goal posts and crossbar are metal or wood and painted on all sides in two contrasting colors. Goals will be firmly fixed to the ground with hooked stakes. The goal line between the goal posts is the same width as the posts. All field markings are 2 in (5 cm) wide and form part of the area they enclose. Lines shall be marked with a white nontoxic material which is not injurious to eyes or skin. For grading and drainage details see Fig. 57. For surfacing details see Fig. 58.

Recommended Area Ground space is 11,230 sq ft (.25 acre) (1,066 m²).

Size and Dimension Playing field width is 65'-8" (20 m). Length is 131'-4" (40 m). Additional area recommended is 6'-0" minimum unobstructed space on all sides.

Orientation Preferred orientation is for the long axis to be northwest-southeast to suit the angle of the sun in the fall playing season, or north-south for longer periods.

Surface and Drainage Surface is to be turf. Preferred grading is a longitudinal crown with a 1 percent slope from center to each side and ade-

quate underdrainage. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading.

Special Considerations Goal posts and crossbar are to be provided at each end of the playing field.

¼-MILE RUNNING TRACK

Fig. 41 (a) Plan-layout of a ¼-mi running track; (b) typical section of track. All distances in lane one shall be measured upon a line 12 in outward from the inner edge of the track. For events run in lanes around a turn, all lanes except lane one shall be measured upon a line 8 in outward from the inner line of the lane.

Recommended Area Ground space is approximately 4.3 acres.

Size and Dimension Inside radius to face of curb is 106'-0". Track width is 32'-0" for eight 4-ft-wide lanes. Overall width is 276'-0". Overall length is 600.02 ft.

Orientation The track should be oriented so that the long axis falls in a sector from north-south to northwest-southeast with the finish line at the northerly end.

Surface and Drainage Track surface is to be preferably bituminous material with a hot plant cushion course mix and optional protective colorcoat-

ing. Maximum slopes for the running track are 2 percent (1:50) inward in the center of curves, 1 percent (1:100) inward in the straightways and 0.1 percent (1:1000) in the running direction.

Special Considerations Drainage must be provided for the track surface and optional football field, but will be dependent upon site grading.

SHOT PUT

Fig. 42 Shot put circle. Throwing circles to be formed of band iron or steel angle 3 in (76mm) × 2 in (50mm) × 1/4 in (6mm) sunk flush with the ground outside. The surface within the circle to be 1/4 in (2cm) lower than the outside level and surfaced with concrete or similar material. Sector lines to be white and marked with either cloth tape, held in place with metal pins, or chalk. Shot put stop board to be made of wood and painted white.

Recommended Area Ground space is 2100 sq ft minimum.

Size and Dimension Shot put circle is 7'-0" (2.134m) in diameter. Throwing sector is 45° angle and 70 ft (21.33m) minimum radius.

Orientation Preferred orientation is for the throwing direction to be toward the northeast quadrant.

Surface and Drainage Surface of inner circle is to be concrete or similar material. Throwing sector is to be turf at the same level as the top of the metal ring.

Special Considerations Stopboard must be firmly fixed so that its inner edge coincides with the inner edge of the shot put circle. Sector flags are required to mark end of landing zone at distance required by the competition.

HAMMER THROW

Fig. 43 Hammer throw circle and throwing cage. All discus and hammer throws must be made from an enclosure or cage to insure the safety of spectators. The cage should be C-shaped in plan, the diameter being 29'-6" (9.0m) with the opening through which the throw is made 26'-3" (8.0m) wide. The height should not be less than 11 ft, but preferably 13'-2" (4.0m). A wire cable, or series of metal struts, is suspended at a height of not less than 11 ft above the ground in the shape of a letter C. The cable or series of struts, is supported in a horizontal plane by eight metal supports made in the shape of gallows, so that the C shape is formed by seven straight panels, each 9'-0" (2.74m) wide. Two movable flaps 7'-7" (2.3m) are provided at the end of the C shape to afford adjustment for different throwing sectors. The eight metal supports are set into the ground with spikes or permanent sockets sunk to a depth of approximately 1 ft (30cm) and held in position with wire ropes. A net 78'-2" (23.78m) long and 1 ft (0.3m) wider than the height of the struts, made of cord 0.5 in (12.5mm) in circumference with 2-in (50-mm) meshes is suspended from the wire or metal strut framework with the lower edge resting on the ground and turned inward. The inner edge should be weighted at intervals with sandbags. Throwing circles to be formed of continuous band iron or steel angle 3 in (76mm) x 2 in (50mm) x 1/4 in (6mm) sunk flush with the ground outside. The surface within the circle to be 1/4 in (2cm) lower than the outside level and surfaced with concrete or similar material. Sector lines to be white and marked with either cloth tape, held in place with metal pins, or chalk.

Recommended Area Ground space is 33,500 sq ft minimum.

Size and Dimension Hammer throw circle is 7'-0" (2.134m) in diameter. Throwing sector is 60° angle and 250 ft (76.20m) minimum radius.

Orientation Preferred orientation is for the throwing direction to be toward the northeast quadrant.

Surface and Drainage Surface of inner circle is to be concrete or similar material. Throwing sector is to be turf at the same level as the top of the metal ring.

Special Considerations For safety all throws must be made from within an approved enclosure or cage. Sector flags are required to mark end of landing zone at distance required by the competition.

DISCUS THROW

Fig. 44 Discus throw circle. Throwing circles to be formed of continuous band iron or steel angle 3 in (76mm) x 2 in (50mm) x ¼ in (6mm) sunk flush with the ground outside. The surface within the circle to be ¼ in (2cm) lower than the outside level and surfaced with concrete or similar material. Sector lines to be white and marked with either cloth tape, held in place with metal pins, or chalk.

Recommended Area Ground space is 25,500 sq ft minimum.

Size and Dimension Discus throwing circle is 8' - 2½" (2.05m) in diameter. Throwing sector is 60° angle and 220 ft (67.06m) minimum radius.

Orientation Preferred orientation is for the throwing direction to be toward the northeast quadrant.

Surface and Drainage Surface of inner circle is to be concrete or similar material. Throwing sector is to be turf at the same level as the top of the metal ring.

Special Considerations For safety all throws must be made from within an approved enclosure or cage. Sector flags are required to mark end of landing zone at distance required by the competition.

JAVELIN THROW

Fig. 45 Javelin throw. Sector lines to be white, 2 in (5cm) wide and marked with either cloth tape, held in place with metal pins, or chalk. Runway may be either turf or bituminous material.

Recommended Area Ground space is 24,000 sq ft minimum.

Size and Dimension Runway length is minimum 120'-0" (36.5m). Runway width is 13'-1 1/2" (4.0m). Throwing sector is 30° angle and 300'-3" (91.5m) minimum radius.

Orientation Preferred orientation is for the throwing direction to be toward the northeast quadrant.

Surface and Drainage Runway may be turf or specialized bituminous surfacing with a maximum slope of 1 percent (1:100) laterally and 0.1 percent (1:1000) in the running direction. Throwing sector is to be turf at the same level as the runway behind the throwing arc.

Special Considerations Foul board is to be provided at end of runway. Sector flags are required to mark end of landing zone at distance required by the competition.

LONG JUMP AND TRIPLE JUMP

SECTION - LANDING ZONE

SECTION - TAKEOFF BOARD FOR LONG JUMP AND TRIPLE JUMP

Fig. 46 Long jump and triple jump. The edge of the takeoff board nearest the landing pit shall be the scratch, or foul line. The construction and material of the runway shall be extended beyond the takeoff board to the nearer edge of the landing pit.

Recommended Area Ground space is 1500 sq ft minimum.

Size and Dimension Runway length is 130'-0" (39.62m) minimum. Runway width is 4'-0" (1.22m) minimum. Landing pit width is 9'-0" (2.75m) minimum. Landing pit length is 32'-0" (10m) minimum.

Orientation Preferred orientation is for the running direction to be toward the north or northeast.

Surface and Drainage Runway preferably is to be bituminous material with a hot plant cushion course mix and optional protective colorcoating. Maximum slope is to be one percent (1:100) laterally and one tenth of one percent (1:1000) in the running direction. Landing pit is to be sand at the same elevation as the takeoff board.

Special Considerations Takeoff board is to be of wood and must be fixed immovable in the runway.

POLE VAULT

POLE VAULT LAYOUT

ISOMETRIC SHOWING JUMPING PIT, STANDARDS AND CROSSBAR

DETAIL - CROSSBAR SUPPORT

DETAILS - POLE VAULT BOX

Fig. 47 Pole vault. Any style of uprights or standards may be used, provided they are rigid and supported by a base not to exceed 4 in. in height above the ground. The crossbar shall rest on round pins which project not more than 3 in (75mm) at right angles from the uprights and have a maximum diameter of 1/2 in (12mm). The crossbar shall be of wood or metal and triangular or circular in section with flat ends. Each side of the triangular bar shall measure 1.181 in (30mm) and the diameter of the circular bar shall be 0.984 in (25mm) minimum, 1.181 in. (30mm) maximum. Length shall be 12'-8" (3.8m) minimum, 14'-10" (4.52m) maximum.

Recommended Area Ground space is 1500 sq ft minimum.

Size and Dimension Runway length is 125'-0" (38.10m) minimum. Runway width is 4'-0" (1.22m) minimum. Vault pit width is 16'-0" (5m) minimum and depth is 12'-0" (3.66m) minimum to 16'-0" (5m) preferred. Height of material in jumping pit is 18 in (0.46m) minimum to 36 in (0.92m) preferred, with a connecting apron of the same material and decreasing height around the vaulting box.

Orientation Preferred orientation is for the running direction to be toward the north to east-northeast.

Surface and Drainage Runway preferably is to be bituminous material with a hot plant cushion course mix and optional protective colorcoating. Maximum slope is to be 1 percent (1:100) laterally and 0.1 percent (1:1000) in the running direction.

Special Considerations Pole vault box must be immovably fixed in the ground with its entire front edge flush with the front edge of the jumping pit. Jumping pit is to be filled with a resilient spongelike rubber or other synthetic material.

HIGH JUMP

Fig. 48 High jump. No point within the takeoff area may be higher than the point of measurement. The horizontal supports of the crossbar shall be flat and rectangular, 1-1/2 in wide and 2-3/8 in long. The uprights shall extend at least 4 in (100mm) at all heights above the crossbar. The crossbar shall be of wood or metal and triangular or circular in section with flat ends. Each side of the triangular bar shall measure 1.181 in (30mm) and the diameter of the circular bar shall be 0.984 in (25mm) minimum or 1.181 in (30mm) maximum.

Recommended Area Ground space is 4,000 sq ft minimum.

Size and Dimension High jump runway is 50 ft (15.24m) radius semicircle. High jump pit width is 16 ft (5m) by 8 ft (2.5m) depth minimum. Height of material in jumping pit is 12 in (0.30m) minimum. Takeoff area is 10'-0" (3m) radius semicircle with centerpoint directly under center of crossbar, and no point within this area may be higher than point of measurement.

Orientation Preferred orientation is for the direction of jumping to be toward the north to east-northeast.

Surface and Drainage Runway preferably is to be constructed of bituminous material with an optional synthetic surface. Surface should be level and unvarying within its arc of 180°.

Special Considerations Jumping pit is to be filled with a resilient spongelike rubber or other synthetic material.

ARCHERY

Target Range

Fig. 49 Archery target range. Space behind and to either side of the range to be clear and free from hard objects. Background behind targets to be preferably dense trees, natural or manmade hills or protective shields. Range to be sited on fairly level land, free from obstructions, preferably sheltered from high winds and oriented to north $\pm 45^\circ$. Standard rounds for adults, 30–100 yd. Standard rounds for juniors, 20–50 yd. Target may be mounted on a round butt of spirally sewn straw or rush supported by a portable softwood target stand. Colors may be painted on an oilcloth cover.

Recommended Area Ground space is 28,600 sq ft minimum (0.65 acre).

Size and Dimension Shooting range is 300'-0" long by 10'-0" wide minimum, 15'-0" desirable, between targets. Roped clear space on each side of range is 30'-0" minimum. Roped clear space behind targets should be at least 90'-0" (45'-0" with bunker).

Orientation Range should be located so that the archer is facing north $\pm 45^\circ$.

Surface and Drainage Surface is to be turf and free from obstructions or hard objects. Drainage is to be preferably from side to side to maintain a constant, relatively level, elevation between the target and the archer at the various shooting distances.

Special Considerations Target is to be provided as prescribed for official competition. Conspicuous signs should be provided to the side and rear to warn people of the range.

Fig. 50 Automatic trap.

Recommended Area Allow 15 acres for a single field.

Size and Dimension Walks and structure occupy an overall area approximately 60 ft deep by 45 ft wide. Shooting stations may be 36 to 40 in square.

Orientation Preferred orientation is for the centerline through shooting station #3 to run northeast-southwest with the shooter facing northeast.

Surface and Drainage Shooting stations are to be portland cement concrete (PCC). Walkways may or may not be paved. Shooting area and 75- to 82-yd-radius minimum cleared area are to be turf. The 300-yd-radius shotfall danger zone

outside of the cleared area may be turf or water or left in natural condition, and the entire field should be located in a relatively flat area with an open background.

Special Considerations If shooting is entirely over land, there should be safety provisions for fencing, posting of warning signs, and clearing away of concealing brush. If shooting is over water, warnings posted on buoys or other signs are required and the trap house should be back far enough from the water's edge to permit recovery of unbroken targets. The trap-house roof must be on the same level as the shooting stations. Contact the National Rifle Association for information on trap-house construction and trap machines.

FIXED NETS AND POSTS

Fig. 51 Badminton and paddle tennis.

Fig. 52 Tennis.

Fig. 53 Volleyball. A 2-in-wide vertical tape marker should be fastened on each side of net directly over court sidelines.

ELEVATION OF TYPICAL FENCE

The diagram illustrates the elevation of a typical fence, divided into a **TYPICAL SECTION** (10'-0" O.C. MAX.) and a **TYPICAL END SECTION** (10'-0" O.C. MAX.).

Typical Section Components:

- TOP RAIL:** 1 5/8" O.D., 2.27# / L.F. PROVIDE EXPANSION SLEEVES 30 ± O.C.
- POST CAP**
- 2" MESH, 9 GAUGE CHAIN LINK FENCE FABRIC (SEE NOTE)**
- LINE POST:** 2 1/2" O.D. OR 2 1/4" x 2" H, 3.65# / L.F.
- TENSION WIRE #7 COIL SPRING**
- 3'-0" MIN. OR TO FROST LINE** (height from ground)

End Section Components:

- BALL CAP**
- TERMINAL POST:** 3" O.D., 5.79# / L.F. OR EQUAL
- TENSION BAR**
- INTERMEDIATE RAIL:** 1 5/8" O.D., 2.27# / L.F.
- TURNBUCKLE**
- 3/8" DIA. TRUSS ROD**
- 10'-0" (height)**

Fig. 56

TYPICAL GRADING AND DRAINAGE DETAILS

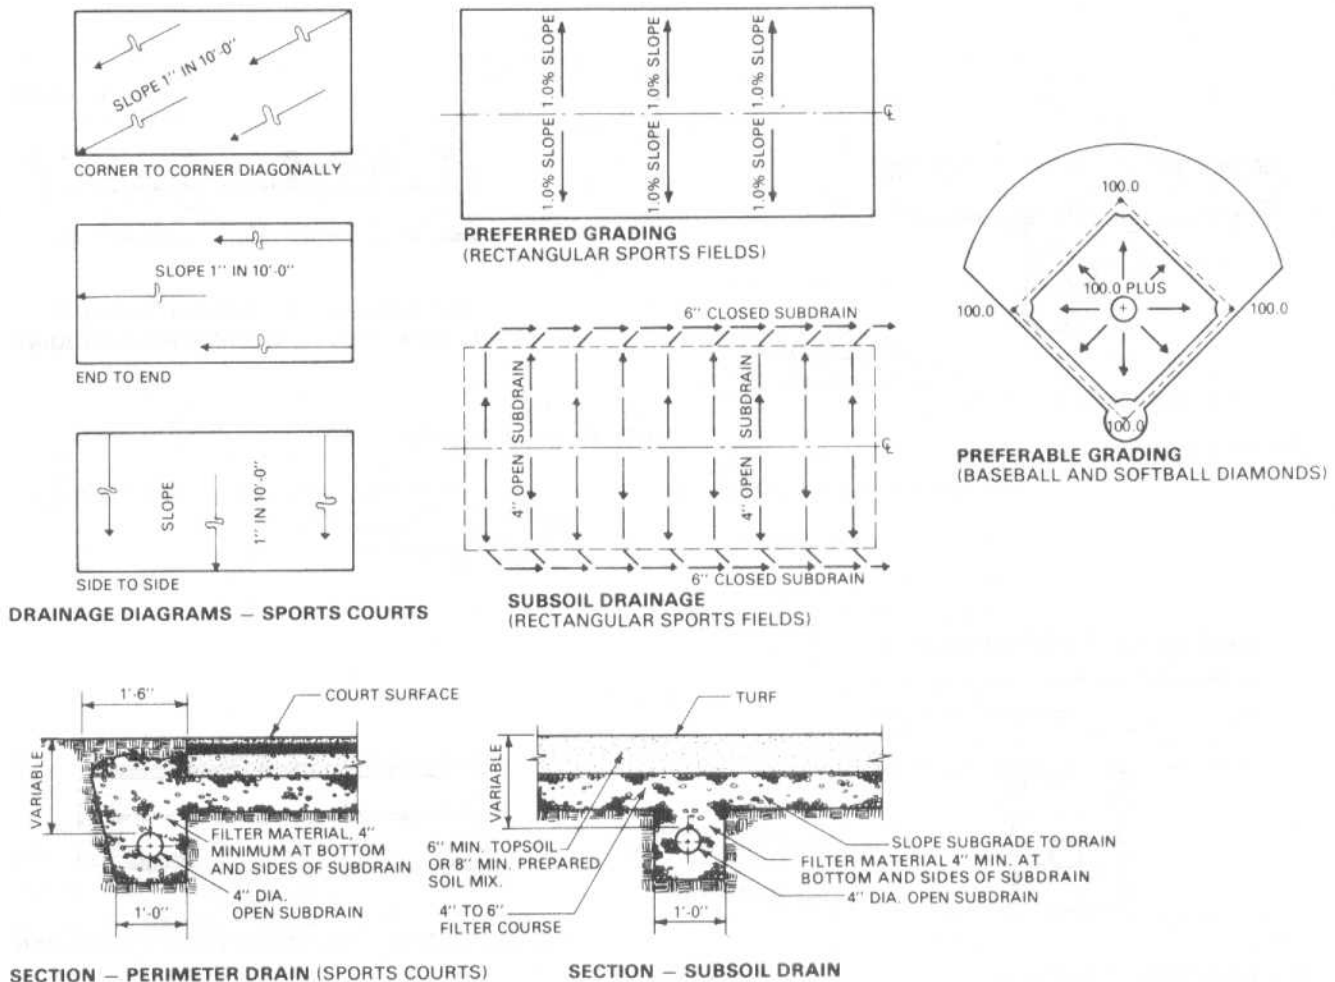

Fig. 57 Grading and drainage. See figure on individual sports for height of pitcher's plate above home plate. It is preferable that the baselines be level. If the diamond must pitch, the average slope shall be 2.0 percent from first base to third base or vice versa. The minimum slope for drainage on turf areas outside the skinned area is 1.0 percent when adequate subsoil drainage is provided. The maximum is 2.5 percent.

Court Surfaces Paved playing surfaces should be in one plane and pitched from side to side, end to end, or corner to corner diagonally, instead of in two planes pitched to or from the net. Minimum slope should be 1" in 10'-0". Subgrade should slope in the same direction as the surface. Perimeter drains may be provided for paved areas. Underdrains are not recommended beneath paved areas.

Playing fields Preferred grading for rectangular field is a longitudinal crown with 1 percent slope

from center to each side. Grading may be from side to side or corner to corner diagonally if conditions do not permit the preferred grading. Subsoil drainage is to slope in the same direction as the surface. Subdrains and filter course are to be used only when subsoil conditions require. Where subsoil drainage is necessary, the spacing of subdrains is dependent on local soil conditions and rainfall. Subdrains are to have a minimum gradient of 0.15 percent. Baseball and softball fields should be graded so that the bases are level.

TYPICAL PLAYING SURFACES

TYPICAL SECTION - NATURAL TURF

Fig. 58 Turf playing surface.

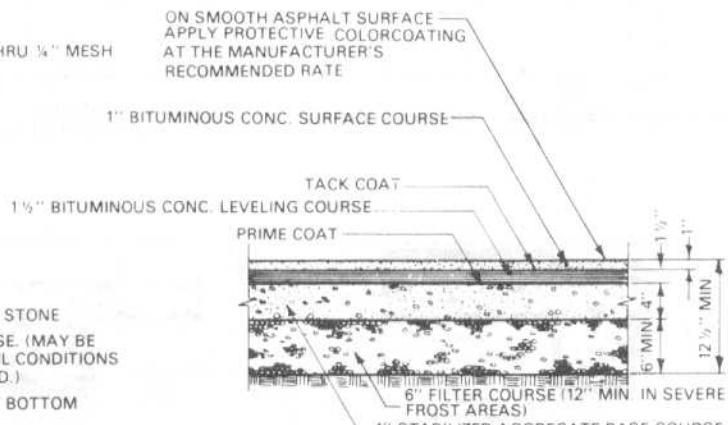

TYPICAL SECTION - CONCRETE PAVING
AND EXPANSION JOINT/CONSTRUCTION JOINT

Fig. 59 Concrete playing surface.

TYPICAL SECTION - SAND CLAY

Fig. 60 Sand clay playing surface.

TYPICAL SECTION - BITUMINOUS CONCRETE PAVING

Fig. 61 Bituminous playing surface.

Concrete (Fig. 59) Minimum compressive strength: 2,500 lb. Reinforcing: 6 × 6-in #6 gauge welded wire fabric. Minimum thickness 4 in. Expansion joints are to be provided as required and doweled 2'-0" O.C. with 3/4-in diameter × 2'-0" long dowel coated on one end to prevent bonding. Joint is to be filled with a 3/4-in foam or preformed bituminous filler and sealed with polysulfide joint sealant. Sand filter course: minimum 6-in deep required.

Bituminous Material (Fig. 61) Base: 4-in minimum stabilized aggregate base course over minimum 6-in filter course. Surface—minimum 2½ in. in two lifts: 1½-in leveling course of bituminous concrete and 1-in surface course of bituminous concrete. Sealcoat: on smooth asphalt surface apply

protective colorcoating at the manufacturer's recommended rate.

Sand-Clay (Fig. 60) Filter course, 4 to 6 in, may be omitted if local soil conditions are suitable. Base course: minimum 3 in of 1½-in crushed stone choked with ¼ to ½ in of crushed fines. Surface course—minimum 4 in. in two lifts: 3-in clay screened through 1-in mesh with a 1-in surface lift of ½ sharp sand and ⅓ clay-silt screened through ¼-in mesh.

Natural Turf (Fig. 58) Subgrade to pitch in the same direction as the surface and slope to underdrains. Filter course, 4 to 6 in, is to be used only when subsoil conditions require. Topsoil 6 in minimum, or prepared soil mix 8 in minimum.

MOVIE THEATERS

By BEN SCHLANGER, Architect
Theater Consultant

Design requirements for cinemas, including auditory and visual considerations combined with showmanship and economy of structure, call for a type of building entirely distinct from stage theaters. The success of a commercial cinema depends on its ability to present good films in an effective manner, affording the maximum volume of patronage at admission prices that will insure an adequate profit. All patrons expect proper vision of the screen image, true reproduction of sound effects, and such comforts as will enable them to give undivided attention to the presentation.

LOCATION

The location of the cinema site is determined by its accessibility, land costs, parking facilities, and potential patronage. Big shopping centers have large parking areas that are generally unused in the evening, and may therefore be desirable locations for motion picture theaters.

SIZE

Home television and new systems of motion picture projection have brought about new criteria for determining optimum seating capacities for motion picture theaters. Home television has greatly reduced the need for the large-capacity (over 1,500 seats) "movie palaces" in urban locations, and also for the small motion picture theater in rural communities. These changes in circumstances place the cinema in somewhat the same category as the other dramatic arts of the living stage theater, where

the success of any one production depends on its quality or unusual character. The new systems of picture projection add a new dimension or an unusual character to a film, but they cannot be depended upon alone to draw the large patronage enjoyed in the era prior to home television.

Technically, the larger screens, wider films (70 mm), and new optical systems (such as Cinemascope) make possible an increase in the size of the audience that can see the film at one time. The increasing competition of home television, however, has made it almost impossible to profit from the potentially larger audience. Reduced patronage and high film-production costs have resulted in higher admission prices, which, in turn, tend to reduce further the size of the audience.

It has only recently been realized that there is a distinct advantage in having a relatively small audience with a maximum-size projected picture. The psychological effect that is thus created is that of "picture dominance," or an "at-the-scene feeling" for the viewer. Under these conditions, the picture practically fills the viewer's central range of vision (approximately 60 deg), and the distraction of the auditorium shell is greatly minimized.

Two distinct types of motion picture theaters have now developed. First is the general type of theater, catering to the more popular taste in films and requiring capacities of from 600 to 1,500 seats. The larger units must have a choice location with an adequate population to draw from and adequate parking facilities.

The second type has acquired the label "art theater." These small theaters are found mostly in the larger cities and in the university towns where there is a more sophisticated audience. Foreign films and

the better U.S. films are shown in these theaters. They usually prove profitable at capacities of from 400 to 900 seats, and often command the highest admission prices.

SHAPE AND SIZE OF PROJECTED PICTURE

Picture shape and viewing patterns are determined by fixing visual standards that enable each viewer to see the picture satisfactorily. The picture must appear undistorted, its view must be unobstructed, and its details discernible.

The average width of the projected picture, which was about 18 ft in 1938, has now approximately doubled for the 35 mm Cinemascope and 70 mm film systems, introduced in 1953. The quality of the projected picture affects the size and shape of the seating pattern. The quality of the projected picture varies with the size of the film used, however, and unfortunately most theaters still use more than one film size and projection system. Although picture widths have increased, the width of standard 35 mm film has not; consequently, when 35 mm film is used, the seats nearest the screen are less acceptable because film graininess becomes visible from these locations. When 70 mm film is used, the seats nearest the screen become desirable since film graininess is greatly reduced and these seats enable the viewers to experience the dramatic impact of "picture dominance."

A more nearly ideal motion picture theater could be designed if only one type of projection system and film width were used. For the best compromise design, to provide for all of the current systems and film widths, the following general guide may be used:

1. The first row of seats should be no closer to the screen than a position determined as follows: The angle formed with the horizontal by a line from the top of

Fig. 1. Method of determining minimum distance from screen to first row of seats

Fig. 2. Maximum viewing distance and maximum width of seating pattern

MOVIE THEATERS

the projected picture to the eye of the viewer in a front-row seat, should not exceed 33 deg. (The top level of the projected picture should be the same for all systems of projection in a given auditorium.) See Fig. 1.

2. The maximum viewing distance should be no greater than twice the width of the widest picture to be projected (Fig. 2).

3. The width of the seating pattern should vary from 1 times the widest projected picture at the first row to 1.3 times at the row farthest from the screen (Fig. 2).

The resultant shape will be less rectangular than the long narrow theaters of the past, which are more economical to build but are unfortunately not well suited for the new systems of projection.

The seats nearest the screen will remain acceptable for use if the following general rule is followed: Projected picture widths should not exceed 35 ft for standard 35 mm film, 45 ft for Cinemascope 35 mm film, and 65 ft for 70 mm film. (See later notes regarding modification of these widths in connection with picture masking.)

In some instances in which a large seating capacity is desired, it is necessary to resort to a balcony in order to avoid the excessive viewing distance that would otherwise develop.

SCREENS AND PROJECTION OPTICS

Projection angle is the angle formed with the horizontal by a line from the projection lens to the midheight of the projected picture. Because of the increased picture width and screen curvatures recently introduced, it becomes increasingly important to have a minimum projection angle (0 deg is ideal but usually impossible). The angle should not exceed 10 deg and should be kept as low as possible in order to have a minimum distortion of picture detail.

A slight curvature in the width of the screen and semimatte screen surfaces are used to increase screen light reflection and to provide better dispersed screen illumination. This extra light is necessary for the larger screen sizes. The curvature should have a radius equal to about $1\frac{1}{4}$ times the projection distance.

PROJECTION LENSES

When a new theater is proposed it is important to determine at the outset the lens requirement for the various film systems to be projected. This information will determine the location of the projection room. The better lenses have greater focal lengths and require longer projection distances.

Fig. 3. Human-figure dimensions used in determining sight-line clearances

Fig. 4. Height of screen above floor at first row of seats

PICTURE MASKING

The most common method for masking the projected picture is to use a matte black surround. This is the simplest and least expensive way to absorb the fuzzy edges of the projected picture. These maskings may be in the form of a curtain that can be adjusted to mask various picture widths.

Another method is to use specially designed walls and ceiling that meet the picture edges. Instead of black trim, the masking is luminous from light reflected from the screen and blends with the projected picture. The author has designed several of these installations that have proved most satisfactory. Eye fatigue is reduced and greater dramatic impact is obtained.

If Cinemascope and 70 mm film are to be used in one theater, the luminous masking frame must be the same size for both systems, in which case a compromise is made by accepting a somewhat larger Cinemascope picture and a somewhat smaller 70 mm picture.

A compromise in the aspect ratio of the screen shape must also be made. The aspect ratio for 70 mm screen is 1 to 2.22 (height to width). For Cinemascope, the aspect ratio is 1 to 2.34. The Cinemascope frame can be cropped in the projector aperture to conform to the 1 to 2.22 aspect ratio without any meaningful loss of Cinemascope picture material.

The shape of the architectural light box in front of the screen requires special study for each seating, projection, and screen pattern.

THIS TYPE OF CHAIR AVAILABLE IN STANDARD WIDTHS OF 19, 20, 21, AND 22 IN.

Fig. 5. Methods of obtaining wider spacing for chairs nearest screen

Maximum spacing for first row is 26 in.

FLOOR SLOPES AND SEATING

In the design of floor slopes and upper level steppings for cinema seating, it is necessary to establish the physical dimensions of the seated patron (Fig. 3) and standards for vision of the screen image. Most important is elimination of objectionable screen obstruction caused by persons seated in front of the viewer. For best dramatic impact, the bottom of the projected picture should be as close as possible to the floor under the first row of seats (Fig. 4). This in turn will require a more steeply pitched floor slope under the seats, and will eliminate the possibility of an upper tier of seats, which would have to be too steep in pitch.

The slope of the main-floor seating would also be increased for one-row vision. One-row vision provides unobstructed vision over the heads of persons in the row immediately ahead. Two-row vision is not ideal, but it is acceptable and permits milder slopes and the inclusion of an upper level of seats. Two-row vision is made more acceptable by staggering the seats to permit a view between the heads of the persons in the row immediately in front. With two-row vision the heads of all persons two or more rows in front will not obstruct any view of the screen. Two-row vision is further improved by using the widest chairs (and therefore the widest space between heads) in the rows nearest the screen. (See Fig. 5.) The view between heads is usually too narrow in the front rows where two-row vision is used. Minimum seat widths should be 20 in. for the rows farthest from screen.

MOVIE THEATERS

THEATER AUDITORIUM FLOOR SLOPES

Unit of reference in motion picture theater design is projection screen width, W . Distance from screen to first row of seats should be no less than $1\frac{1}{2}W$. Best viewing distance is zone 3 W to $4W$; next in desirability are areas $2\frac{1}{2}W$ to $3W$, and $4W$ to $4\frac{1}{2}W$.

In theater of 22 rows, a screen 11 ft high by 15 ft wide is good for maximum viewing distance;

hence, first row of seats should be about 15 ft from screen. Recommended row spacing at least 34 in back to back.

Upward floor slope should start as far back from screen as possible, since slopes greater than 3 in between rows require risers. In diagrams shown (Figs. 6, 7, and 8), staggered seating, except in first rows of reverse-pitch schemes, reduces rear floor slope by half, and avoids dangerous

variable step heights necessary with aligned seating. When steps are used, if uniform height (fixed by rear rows) is adopted as standard, slope increases, and stadium type scheme results. Elevated stadium type is useful to permit space beneath for passage and services.

Drawings show all levels in relation to datum line, lowest point of floor. All pitches and rises noted in inches and decimal parts of an inch.

Fig. 6 Single-slope auditorium. On ground sloping 3 ft or more downward toward screen. Without staggered seats, risers required starting tenth row.

Fig. 7 Double-slope auditorium. On level ground, or on ground sloping less than 3 ft in any direction. First six rows aligned to allow view of entire screen.

Fig. 8 Double-slope auditorium with stadium. On level ground or on ground sloping less than 3 ft in any direction. Seats in at least first six rows aligned. Crossover under first few rows of stadium saves seating area. Staggered seating and minimum clearance in crossover prevent intermediate steps.

MOVIE THEATERS

Fig. 9 Example of "continental seating."

Cinema at Turku, Finland; Erik Bryggman, architect. Minimum row spacing of 40 in. is required. More seats can be used in width to conform to larger screen requirements.

ROW SPACING AND AISLES

Minimum spacing between rows should be 34 in., with 1-in.-thick chair backs. Greater chair-back thickness is wasteful and unnecessary. Where 40 to 42 in. can be used for row spacing, many building-code authorities permit the elimination of all longitudinal aisles other than the aisles against the side walls. These codes, however, require frequent exit doors along the wall aisles for this type of seating. The capacity is about the same for the 34- and 40-in. spacing because of the different aisle arrangement.

The 40-in. seating scheme is sometimes termed "continental seating" because of its popularity in Europe. The extra comfort and safer egress afforded by this arrangement account for its increasing use. (See Fig. 9.)

SCREENS

All screens are perforated to allow for sound transmission from speakers placed behind the screen. (A depth of 5 ft should be provided behind the screen for the speakers.) All screens are vinyl plastic with a diffusive surface or a coated surface to increase light reflection. Lenticulated screens are also available. The screen material must be selected in accordance with the shape of the seating pattern and the strength of the projector light source.

GENERAL LIGHTING

The lighting of a cinema auditorium serves three separate functions: (1) Emergency exit and mood lighting, used during screen presentation; (2) Lighting needed during intermissions; and (3) Lighting of sufficient intensity for making announcements, clearing the house, or other rare occasions.

Types and sources of light for these needs are as follows: (1) Light reflected from the screen, of varying intensity dependent on film density; (2) Wall and ceiling surface illumination by standard lamps or tubes installed on the surface to be illuminated; and (3) Light projected on walls, ceiling, or audience from remote or concealed positions. All lighting normally required during the presentation is supplied in the front half of the auditorium by screen-reflected light. The rear portion must be illuminated by other light sources, placed so that the source is not within the spectators' normal range of vision. Placement choices are: first, at the junction of ceiling and side walls; second, on the ceiling; and third, on the side walls. The side walls rarely offer an acceptable location because, here, even low intensities are often objectionable.

Lighting during a performance should consist of a low-intensity, evenly diffused bath of light completely covering all surfaces in view, rather than either complete darkness or spotty lighting.

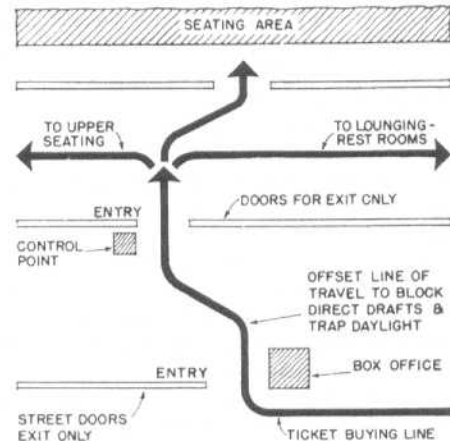

Fig. 10 Circulation diagram, showing relation of street lobby, foyer, and auditorium doors.

In considering the utilization of screen-reflected light, it is important that areas immediately surrounding the screen should not cause a lack of clarity in the projected image. Surfaces closest to the screen can be shaped, finished, and related to the screen surface so as to enhance the picture.

Emergency lighting generally must be provided separately. Where separate service lines are available, one may be used with an emergency motor generator. Alternative means of providing energy are battery systems kept charged automatically, gasoline, Diesel or gas engine generators, water turbines, and the like.

Exit signs are connected to the general emergency lighting circuit and should be legible from any point viewed. Lettering is usually a minimum of 8 in. high. All circulation areas, including foyers, lounges, and lobbies should likewise be on the emergency circuit.

TICKET BOOTHS

The location of the ticket booth depends on the space available, the character and direction of street and pedestrian traffic, and the volume and habits of patronage. The ticket booth may be isolated (as an island), centered, or included in the corner of the entrance. It should, of course, be readily identified with its function. In metropolitan areas, ticket booths are almost universally placed as close to sidewalks as building codes permit in order to attract casual passers-by. In suburban and other centers where patrons leave their homes with the express purpose of attending the cinema, ticket booths may be removed from sidewalk lobbies and placed either within secondary lobbies or in foyers. It is pos-

MOVIE THEATERS

sible to adopt a continental custom—use of an open counter located conveniently to the manager's office—in an effort to achieve an "intimate" atmosphere. When operated by only one person an area approximately 4 by 4 by 8 ft is adequate; for larger theaters, where there are generally two ticket sellers, clearances are required.

Heating is often provided from the theater heating system if the theater cellar extends under the ticket-booth space. Although electric heaters are sometimes used, they are not always satisfactory because they concentrate great amounts of heat in single spots without providing general heating. Natural ventilation is usually provided by ventilators in roofs and louvers in doors. Occasionally air-conditioning ducts are run to booths from theater systems. Space is required for change makers and electrically or manually operated ticket dispensers. It is almost universal practice to install an outside telephone for the attendant's convenience in answering calls about the program. This telephone is usually connected to another in the manager's office, with a two-way signal.

LOUNGES AND TOILETS

Lounge areas, on either level, serve to separate the toilets from the theater seating. For capacities of over 600 seats, at least two lounge areas should be provided and arranged so as to be partially or wholly visible from the lobby, foyer, or circulating areas. It is also desirable to have some part of the lounge command a view of both seating and screen in order that waiting patrons may follow seat availability as well as performance progress.

Recommended minimum toilet fixture requirements are as follows:

Theater capacity	Men	Women
Up to 400 seats	1 basin 1 toilet 1 urinal	1 basin 2 toilets
400–600 seats	2 basins 2 toilets 2 urinals	2 basins 3 toilets
600–1,000 seats	2 basins 2 toilets 3 urinals	2 basins 4 toilets

Local codes, of course, will govern.

PROJECTION ROOMS

The usual code requirements are 48 sq ft for the first projection machine and 24 sq ft for each additional projector. Dimensions based on necessary clearances around projectors are given in Fig. 11.

Rewinding: Although at least one state law requires that film rewinding be done in the projection room, a separate rewind room adjacent to the projection room is usually considered advisable. Rewinding is done on a small table; observation ports opening to both the projection room and the auditorium permit a single operator to supervise a presentation easily while rewinding used film.

Film storage: Up to 12,000 ft of film is usually permitted to be stored in metal containers. Film safes are required for greater amounts, 24,000 ft being the usual maximum. The location should be convenient to the rewind table.

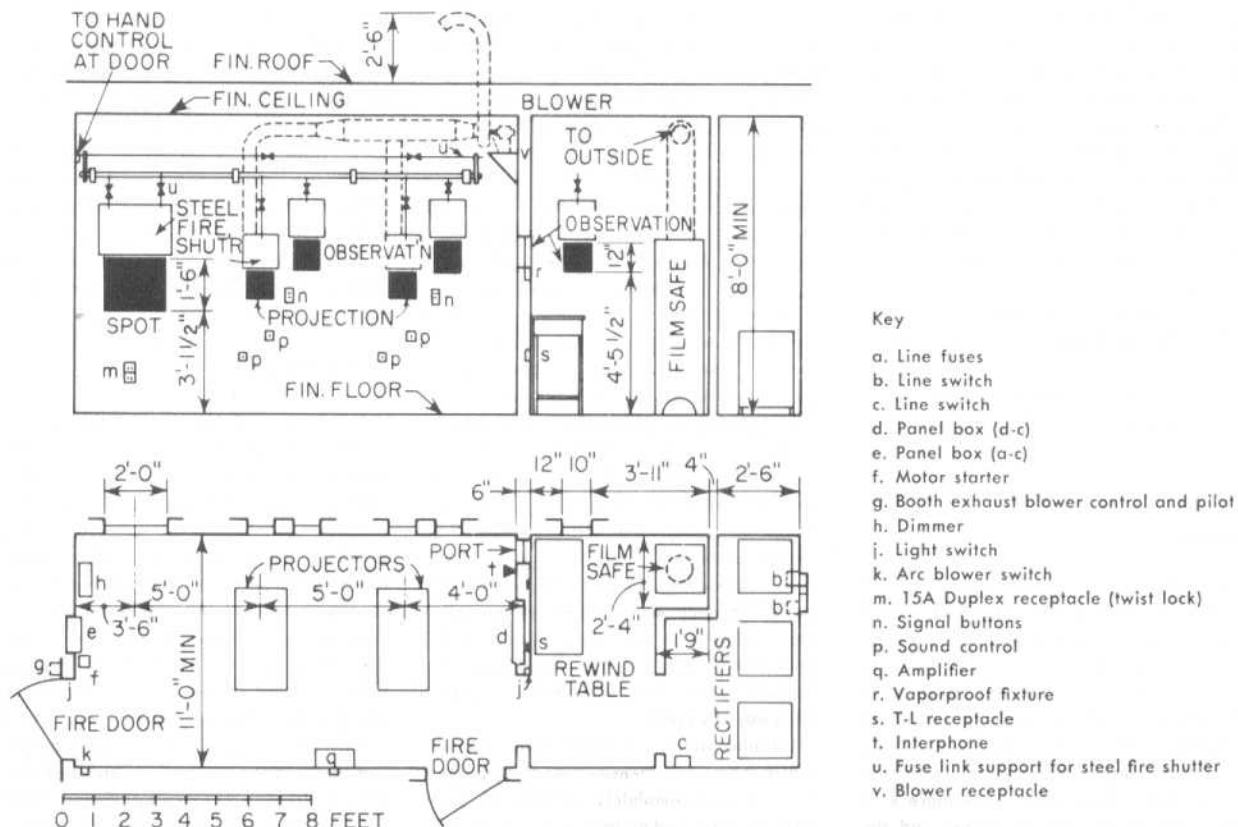

Fig. 11 Plan of projection room and elevation of wall toward auditorium.

A sufficient area of inexpensive land is the prime consideration in selecting a site. Location is generally better close to town, but theaters have been successful several miles from city limits. Many states and communities are developing codes regulating location and design of drive-ins; these should be carefully investigated. Other factors to check include: proximity to other drive-ins; nature of soil; natural drainage; simple, cheap excavation and grading; nearness to railroads or other distracting noises or odors. Drive-ins are usually best located on secondary roads connecting with major highways to prevent traffic congestion. Outside city limits, septic tanks must often be used for waste disposal, wells for water supply. Theater size should be derived from potential patronage; an average of 3.28 patrons per car was reported by *Theater Catalog, 1949-50 Edition*, from a survey conducted in the Minneapolis area.

Plot Layout

Ramps The theater area is a series of ramps, laid out one behind the other in arcs. They are graded to elevate the front of each row of cars, permitting vision of screen above cars ahead. Sight lines and road grades must be established by size and terrain.

Capacity and Size Maximum capacity is limited by number of ramps possible with clear view of screen. Picture size is limited to lenses and projection equipment available. Until larger and brighter pictures are possible, about 1,000 to 1,300 cars is maximum. Smaller theaters generally average about 450 cars, larger ones near cities, 650 to 1,000 cars. *Motion Picture Herald* (Feb. 14, 1948) recommends roughly 100 ft of width for each 10 cars, and the following depths (based on full radii ramps, 38 ft o.c., and speaker posts 17 ft o.c.):

No. of cars capacity	No. of ramps	Screen to rear of ramps, ft
500	10	510
586	11	548
670	12	586
778	13	624
886	14	662
1,000	15	700

See Figs. 1 to 3.

Entrances and Exits Provide waiting space or extra wide entrance drives to get cars off highways; say for around 30 to 40 percent of capacity. An escape exit drive by ticket office gives patron a means of getting out when cars are stacked behind him. On leaving ramps, it is best to have cars drive forward for exit. Several well lighted exits will ease traffic congestion. Often front-footage is retained for commercial use.

Surfacing Drives should minimize dust and not be slippery when wet. Crushed stone topped with gravel, oil treated or black topped, is often used.

Ticket Booths Ticket selling must get patrons in quickly to start show on time. One ticket booth can usually serve up to 300 car capacity, two up to 600, three up to 800, and four up to 1,000 cars.

Screens Screen towers should be placed so pictures cannot be seen from highway. Screen widths vary from 40 to 60 ft, depending on number of ramps and topography. Sizes often used are: 48 by 37 ft for 650 cars, 56 by 42 ft

for 950 cars. It is desirable to face screen east or north; this blocks evening sun, permits earlier show. Height above ground is determined by ramp and sight angles. Tilting screen at top minimizes distortion.

The screen may be of almost any material which will take a good covering of white paint; provisions should be made for frequent and rapid repainting. Asbestos sheets, aluminum and steel decking have been used. Minimize joints to prevent distortion and streaking. The structure should withstand at least 25 lb per sq ft wind pressure and be fire-resistant. Wood frames, structural steel, reinforced concrete, even telephone poles are used. Prefabricated units are available.

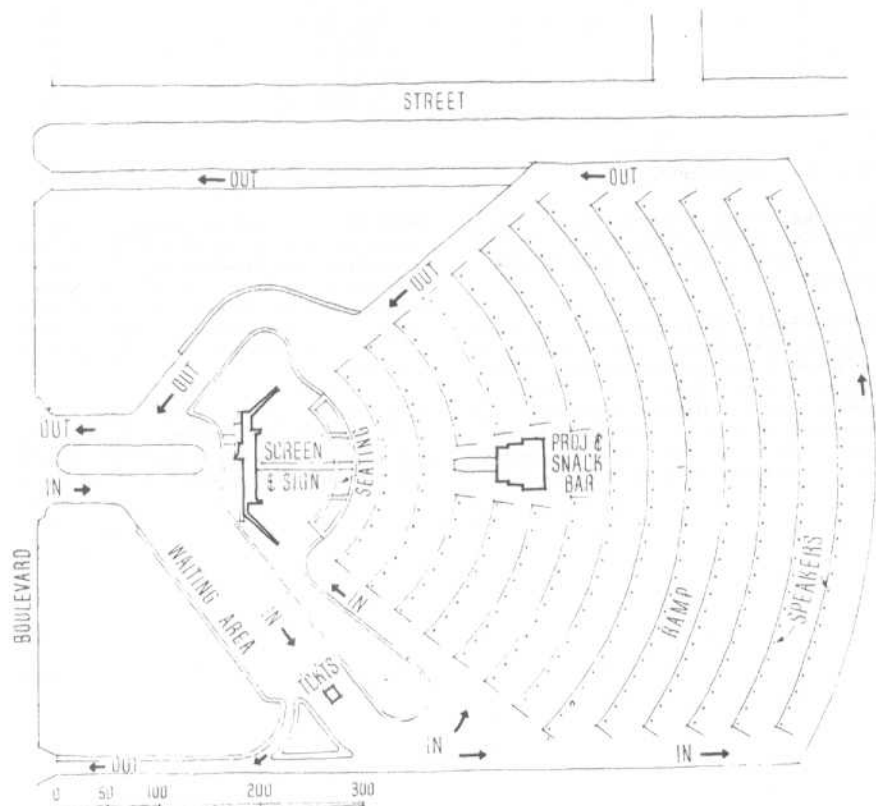

Fig. 1 Typical layout.

Fig. 2 Typical profile.

Recreation and Entertainment

DRIVE-IN THEATERS

Fig. 3 Back-to-back theaters.

Seating Area If near residential areas, provide seating for walk-in patrons, in front of screen or by concession. A children's playground is desirable.

Projection Booth Picture size and focal length of lens control placement and design of projection booth. It is often placed about 280 ft from screen, centered in lot. Special lenses can project greater distances. Projection angle depends on ramp layout. The booth must house two operators, two projectors, a large generator, and an amplification system for speakers.

Speaker Units Sound is best served by "in-car" speakers on posts about 16 to 18 ft o.c. Each serves two cars. Speakers may be removed from posts and hooked inside cars. Underground cables supply power. Aisle and signal lights are built into many commercial models. Electric car-heaters may be used for cool weather.

Concessions Attractive, clean and roomy snack bars can be an important source of income. Large numbers must be served quickly during intermissions and before showings. A

Fig. 4 Projection room/snack bar.

terrace in front of concession allows continued viewing. Illumination must not detract from screen during showing. Service carts are used for ramp service; signal lights or an inter-communication system may be used for calling carhops (Fig. 4).

Storage Space is needed for cleanup and repair equipment, and for supplies. If speakers, junction boxes and projection equipment are removed for winter, safe, dry storage is needed on site or in a warehouse. If left in place, waterproof covers should be used. Sprays for insect control, and fire extinguishers should be on hand.

Design Notes Illuminated signs should be placed near highway, but so as not to form a traffic hazard. The back of the screen is often used for advertising. Fencing should be high enough to cut off headlights of cars on highways. Simple, neat landscaping can help maintain desirability in the community and attract customers.

PRELIMINARY CONSIDERATIONS

The following factors dictate the plan of a bowling center:

1. The ability of an area to support the business
2. Public or private operation
3. The available capital for the immediate venture
4. Property size, location, and zoning
5. New or existing building
6. Parking requirements, required by law and for the operation of the business
7. Desired allied businesses and the local ordinances in force which govern such businesses as the following:
 - a. Liquor bar or cocktail lounge
 - b. Snack bar or restaurant
 - c. Billiard room
 - d. Meeting rooms and banquet facilities
 - e. Other sport facilities
 - f. Retail sale of bowling and other sporting goods
8. Automatic pinsetters or manually operated pinsetting machines
9. Selection of ball return equipment
10. Type of lane foundation
 - a. 2- by 4-in. stringer foundation with 9-in.-deep pit
 - b. Built up crib foundation where noise reduction is necessary or where no pit is provided
11. Automatic scorers

SITE PLANNING

Because a bowling center is a permanent building, the placement of any such structure on a parcel of property merits intensive study. The future general long-range planning for the surrounding area, contemplated zoning changes involving building lines, future road building, or anything which could alter the present character of the property should be considered at this time.

The site can be planned with relation to the following items:

1. Zoning of land restricting commercial, business, or parking.
2. Local nearby church or school building which might restrict traffic or the sale of alcoholic beverages.
3. Proposed maximum future expansion.
4. Drainage requirements, location of soil and storm sewer lines, public utilities.
5. Maximum visibility of building from street—nearby location of buildings, railroad overpasses, trees, signs, etc.
6. Availability of parking requirements for the maximum number of lanes.
7. Distance from bulk of parking related to entrance to building. This ultimately dictates location of bowling lanes and layout of public area facilities, such as control, liquor bar, snack bar, pro shop, check room, as they relate to traffic patterns within the building.

8. Traffic flow restrictions to entrances and exits from the property.

9. Certified soil sample test to determine if ground can support weight of a suitable building for bowling plus hydrostatic pressure.

PARKING

To accommodate the majority of bowling patrons that arrive at the lanes in cars, it is essential to provide parking facilities.

If the site allows, parking is generally preferred as close to the main entrance as possible (Fig. 1).

The parking area should be well illuminated; and, ideally, it should be paved, drained, and, in the instance of head-to-head parking, should have wheel bumpers. Blacktop is preferable to crushed stone. Blacktopping should be sealed annually.

On a national average, seven cars per lane is the general minimum requirement.

Many establishments use car jockeys during the busy hours. This speeds up the entrance of bowlers and helps conserve parking space. Usually, the tips pay for the car jockeys. Insurance is necessary.

Occasionally, music is piped into the parking areas.

It would be advisable to locate water connections throughout the parking areas. This is needed to clean the parking lot and eliminate dirt tracked into the building.

Shrubby has frequently been used as a screening device to minimize the glare from

headlights and to reduce motor noise in the parking areas, but such shrubbery should not block the view of passing traffic or exits and entrances.

Special attention should be paid to exits and entrances. It is necessary to clearly identify the entrances to the parking facilities. These entrances, as well as the exits, should be located so as not to interfere with the flow of highway traffic. Ideally, incoming and outgoing cars should not have to cross the flow of traffic.

BUILDING WIDTH

The width of the building may be determined by adding the thickness of outside walls, the width of side aisles, and the required space for columns if they exist, to the width of uninterrupted bowling lane bays. Dimensions for bowling lanes are noted in Fig. 2. Remarks concerning columns and side aisles follow.

1. Column Spacing

Naturally any designer would rather work with a clear span. However, in those establishments where supports for the structure above the lanes dictate that columns be used, it is desirable to use a minimum lateral spacing between columns of 22 ft-6 1/4 in.—a four lane bay plus 1 in. for clearance—to reduce transmission of noise up or down the structure of the building (Fig. 3).

Longitudinally, the fewer columns, the better. The 16 ft-1 1/8 in. of the approach area and

Recommended Parking Dimensions

A	DIRECTION OF PARKING	B	C	D	E	F	G	NO OF STALLS IN LENGTH "X"	AREA PER CAR

MINIMUM CLEAR UNOBSTRUCTED PASSAGE TO PIT AREA _____ 6'-0" WIDE x 6'-8" HIGH.

REAR OR SIDE OF SERVICE AISLE (SECONDARY CHOICE)

MINIMUM CLEAR OPENING _____ 6'-0" WIDE x 6'-8" HIGH.
MINIMUM CLEAR UNOBSTRUCTED PASSAGE _____ 6'-0" WIDE x 6'-8" HIGH.

IF THE OPENING IS WITHIN 6'-0" OF ANY PART OF THE KICKBACKS, THE MINIMUM UNOBSTRUCTED OPENING SHALL BE 6'-0" WIDE x 6'-8" HIGH ABOVE KICKBACKS

Fig. 2 Key bowling lane dimensions.

at least 2 ft beyond the foul line, if possible, should be kept completely free of columns.

2. Side Aisles

The width of the side aisles is determined by the economical width of the building. The side aisle performs as a convenient indoor route for house personnel between the bowlers' area and the service aisle behind the pinsetters. It is not normally designed for use by the public or for the movement of equipment and supplies. A side aisle on each side of the building also eliminates the mental hazard of bowling "hard against the wall" on the first and last lanes.

BUILDING DEPTH

The depth of the building can be established by starting at the rear of the building. First, consider the requirements for storage and shops for equipment. Then, follow the requirements for the service aisle, the length of the bowling equipment installation, bowler and spectator seating arrangements, concourse requirements for special seating and traffic flow, and, finally, the companion accommodations. Remarks concerning each of the above follow.

1. Storage, Shops, and Service Aisle

Where the lot size affords the space, many of the larger bowling establishments erect a "lean-to" type of structure behind the rear wall of the building with entrance to this structure through fire-retarding doors, directly from the service passage. This structure can also be built against one side of the building if plot is too shallow. The purpose of this appendage to the main building is for storage of bowling supplies such as pins and spare parts, shop area (pinsetter tool room, 150-sq-ft minimum) for the fully automatic pinsetters, and toilet. Since the pit area is a noisy area, the shop should be so constructed as to be as quiet as possible, to achieve maximum working efficiency of the mechanic, although walls are not required between the storage area and the service aisle. Pay particular attention to the location of ducts and pipes which will conduct noise unless properly insulated and isolated. The depth of this structure generally varies from 8 to about 14 ft, while the width depends on the space required for the above mentioned operations. A minimum of four sets of pins per lane is usually stocked. The size of a corrugated cardboard carton of 10 pins is 9 in. deep by 16 in. by 18 in., approximately.

2. Equipment Length

The length of the bowling equipment installation is determined by using a recommended 5-ft (minimum 3-ft) clear service passage behind the lanes plus the overall length of the bowling lanes, which is 83 ft-2 in. and includes the pit, bed, and approach. To these figures, add 12 ft for bowlers' settees used with cluster subway returns or with in-line subway returns (alternate location). If in-line subway returns (standard location) or in-line surface returns are used, substitute a minimum 9-ft dimension for the 12-ft settee dimension stated above. Several examples of lane installations are provided in Figs. 4 to 7.

3. Spectator Seating

Each desired row of straight spectator seating requires a minimum of 3 ft-6 in.

If the new tables and ball racks are to be

Fig. 3 Column spacing illustration.

incorporated behind or in place of the spectator seating, check carefully with your sales engineer regarding the suggested layouts for this equipment. Concourse tables and chairs can help convert the spectator audience into an income producing audience.

4. Concourse

The concourse or promenade, which is in back of the spectator seating, may vary in width. The clear width of the concourse should be ample to accommodate at least a peak load of 10 people per lane, and its maximum width is at the milling area, generally centered around the control counter, check rooms, and entrance lobby. The peak traffic load is usually experienced at changeover time when more than one league is in the house. Vending machines, ball cleaners, etc., are frequently located on the concourse. Adequate wall area or other provision should be considered for bulletin boards, league standing score sheets, and other announcement boards. Unless house ball storage racks are considered with spectator seating as outlined under "Spectator Seating," it will be necessary to consider this factor on the concourse.

5. Variables—Companion Accommodations

The design of the companion accommodations includes such items as the following.

Cocktail bar	Billiard room
Liquor bar	Nursery
Snack bar	Office
Precooler	Checkroom
Game room	Control
Toilets	Heating-humidity control and air-conditioning equipment
Locker rooms	Quick service bar
Lounges and powder rooms	Retail sports shop
Janitor's closet	
Pay phones	
Meeting rooms	

The control desk, the bar, snack bar, checkroom, and shoe rental must be proportioned to capacity conditions in the lanes and should be easily accessible from any part of the lanes.

Normally, a full-scale restaurant is not considered a profitable adjunct to bowling. There are exceptions, however, to disprove this rule.

All air-conditioning equipment need not be placed within the building. Often some of this equipment is placed alongside of, or on the roof of, the front end of the building in an area where space is not so valuable.

All of the foregoing are ideally placed behind the concourse, although they may be placed alongside the lanes, if necessary—provided care is taken to eliminate the hazard of distraction to the bowlers (Fig. 8).

Control The control complex is the functional heart of the entire bowling operation and sets the character of the house. Since the control is constructed by the owner or his builder, it varies with each house in size, decor, and location (Fig. 9). The following things are constant in all control counters:

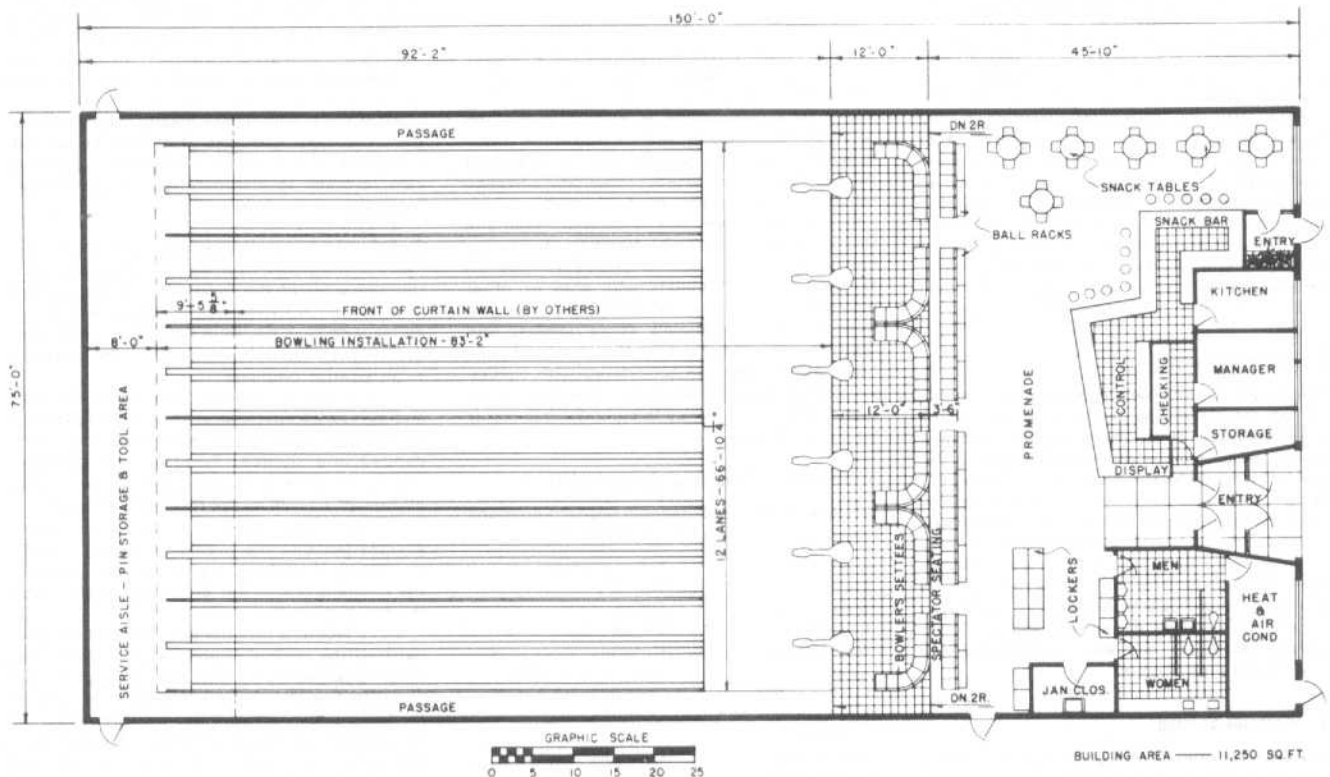

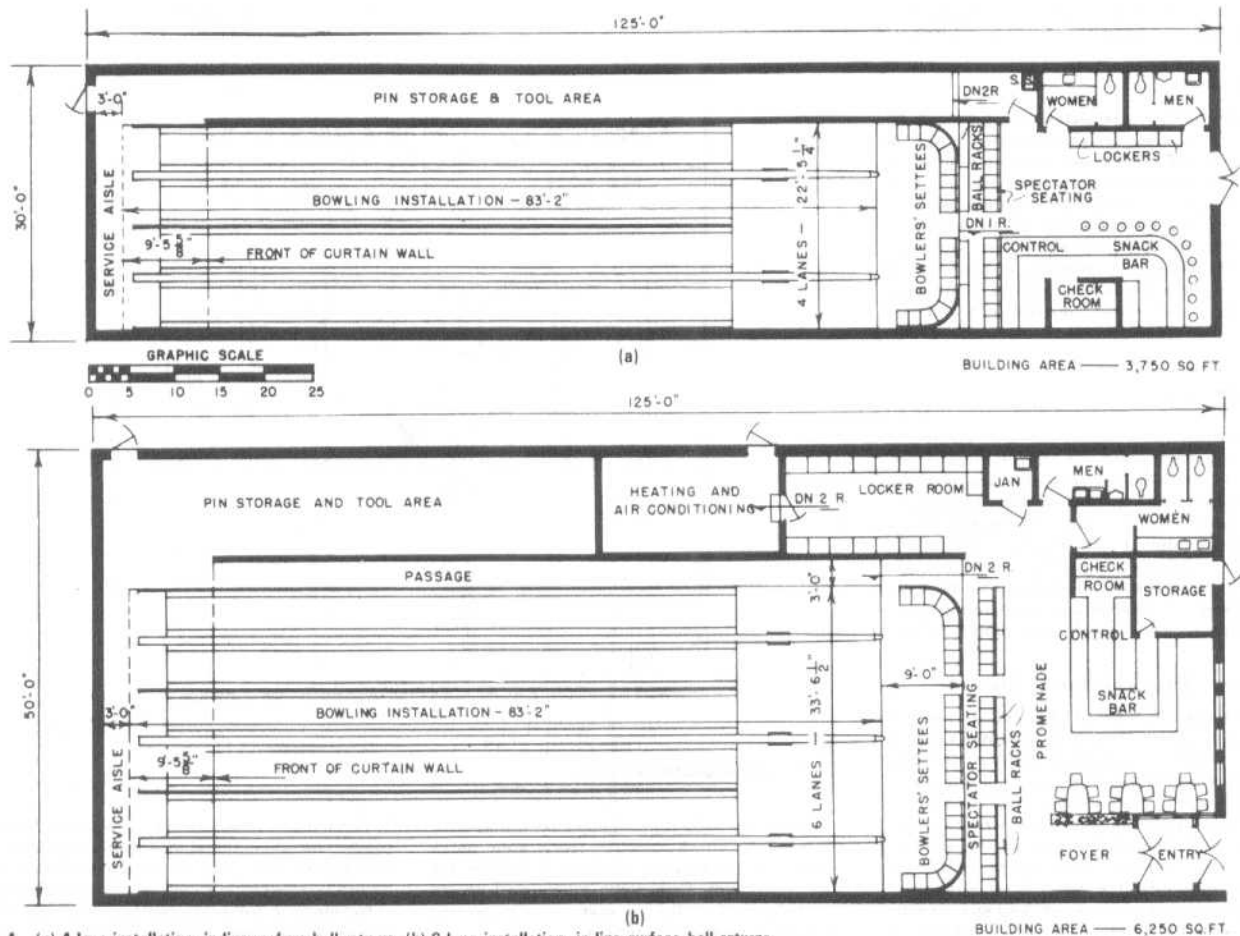

1. It is the point where management greets and serves its customers. Therefore, it should be located prominently and should be well defined and lighted. From it, the operator should be able to supervise main exits and entrances, as well as the bowling lane area.

2. Since the control counter attendant assigns lanes to the public, it should contain necessary switching equipment to activate the bowling equipment and house lights over the bowling area.

3. To facilitate internal communications with patrons, the control counter also contains the public address equipment, which may be also connected with music. Intercom or phone facilities to the office, pits, or other areas of the building are also located here. A public telephone for receiving reservations or phoned messages for the house or its patrons should be included, but patrons should not be permit-

Recreation and Entertainment

BOWLING ALLEYS

BOWLING ALLEYS WITH BILLIARD ROOMS

ted to use this phone to conduct lengthy conversations. They are instructed to use pay phones provided for that purpose.

4. The control issues score sheets, which are collected at the end of the play. The tally of these sheets must correspond with the bowling revenue collected. For this reason, storage space for new and used bowling score sheets and a cash register are required.

5. Depending on the selected operating procedure of the installation, rental bowling shoes may be issued at the control desk directly to the customer, or a receipt may be issued to the customer at the control desk for rental shoes to be procured at the checkroom or pro shop or the house ball storage room. In the event the control counter will issue the shoes, sufficient storage space for these shoes must be provided. This space should be ventilated and so designed as to prevent the accumulation of dust and dirt. A shoe sanitizer is needed. Shoes should be kept within easy reach of the attendant.

6. Many proprietors use the control counter

to help display resale items, such as balls, bags, and shoes. They also dispense such bowler's aids as ball cleaning fluid, bowling sox, grip aids, etc. These items should be displayed within sight but not within reach of the customer. In larger establishments, retail sales of bowler's equipment and supplies are often handled at a pro shop where these items, together with bowling apparel and trophies, are stocked. The merits of this decentralization must depend on each individual installation.

7. Control area should be able to observe billiard activity and have easy access to bar and/or snack restaurant area. This provides maximum utilization of personnel in slow periods of play to keep payroll at a minimum.

Billiards In many areas of the country, the companion use of billiards in bowling establishments has proved to be an extremely lucrative addition to the business. Some communities have distinct ordinances governing public billiard rooms. On an ever widening scope, the billiard room is being planned as a semi-

open area off the concourse and within easy control of the bowling control desk, which issues the playing balls (including the cue ball and chalk) in plastic racks. The customer is obliged, then, to return the full set of balls when play is completed or forfeit his deposit paid earlier (Fig. 10).

Adequate player seating is a must. Generally, a minimum of two seats per table is provided. Sand urns for cigarettes are also needed—ash trays get lost. Cocktail tables for soft drinks and sandwiches may also be provided.

Frequently, small groups of tables are sectioned off by screen-type dividers within the room. This requires considerably more space, although it affords a luxurious air of semi-privacy. Care must be taken to see that visual control is still maintained.

A small space will be required for repair of cues and general billiard storage.

Normally, three cushion or carom or snooker tables are isolated from pocket billiard tables.

A minimum of 57 in. for cue clearance is

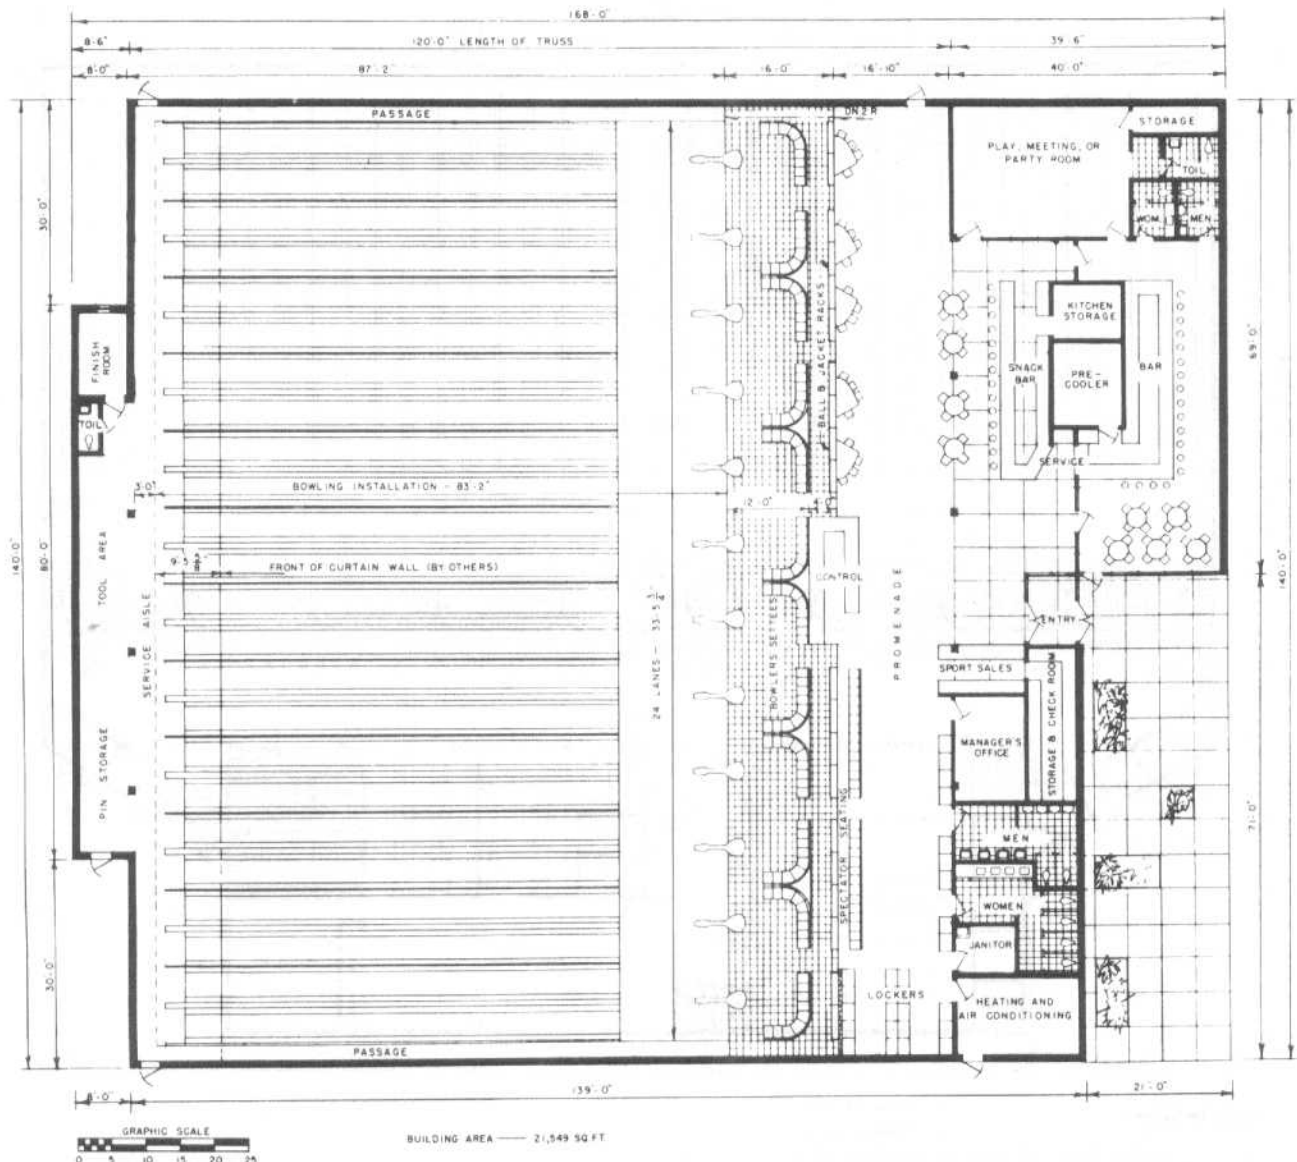

Fig. 6 24-lane installation, cluster ball returns.

BOWLING ALLEYS WITH BILLIARD ROOMS

needed between the table rail and any obstruction over 30 in. high.

The rooms generally have floors of vinyl asbestos tile or carpet. Carpet wears out three times as fast; vinyl tile or vinyl asbestos is recommended.

Lighting of 50 to 75 footcandles of even intensity on the entire playing surface, which is 30 in. above the floor, is usually accomplished with flush ceiling-mounted-type fixtures centered over each table or with a complete luminous ceiling to eliminate shadows on the tables. Light sources should be shielded with louvers.

Walls are light colored, decorative, and resistant to scuffing and soiling. Vinyl-coated products are frequently used for wall covering.

Meeting Rooms and Nurseries Meeting rooms and nurseries are often combined to perform a dual purpose. In this respect, it is necessary to

survey the potential use of each function to ascertain that schedules will not coincide or overlap. Meeting rooms generally require storage closet and toilet facilities, food and beverage service, secondary egress, motion picture machine outlet and screen.

Nurseries require storage closet and toilet facilities, drinking fountain, and secondary egress (may be to an enclosed exterior play yard).

General lighting should be no less than 50 footcandles of even illumination.

In some areas, the word *nursery* implies the use of a registered or practical nurse. Therefore, the word is often changed to *children's playroom* or *toddlers' room*.

Locker Rooms The locker room is for ball storage cabinets only.

Normally, separate locker rooms are provided for male and female patrons. These are

generally located in conjunction with the main bank of toilet facilities, and it is advantageous to plan access to the toilets through the locker rooms. This continuous traffic through a locker room is a deterrent to loiterers and malefactors. A bench for changing shoes is needed. In the case of women's locker rooms, this area often encompasses the powder bar area and lounge.

In some areas, particularly the west and southwest, the locker room is a combined area open to the concourse and accommodates both sexes. The popularity of this arrangement is growing rapidly since it conserves space and provides for family use of one facility.

The locker room usually has a vinyl asbestos tile, ceramic tile, or terrazzo floor for easy cleaning. The room should be well lighted and ventilated. Since the ball storage cabinet units stand 6 ft tall against the walls, no particular wall treatment except paint is needed. In many

Fig. 7 36-lane installation, cluster ball returns; 8-table billiard room.

BOWLING ALLEYS WITH BILLIARD ROOMS

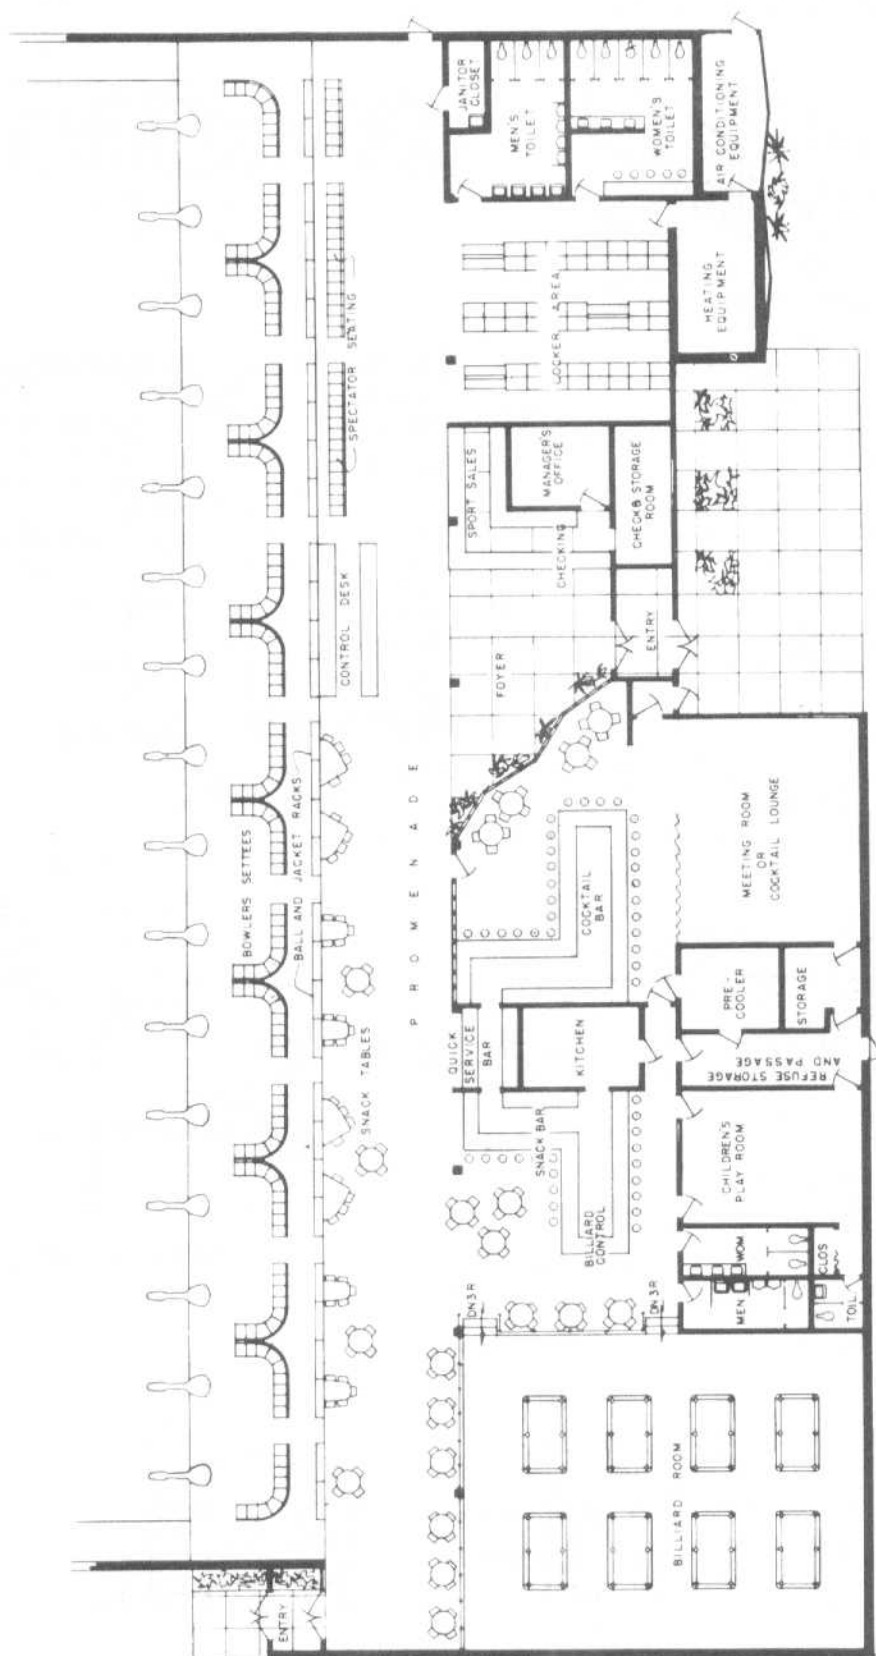

Fig. 8 Area of public occupancy.

BOWLING ALLEYS WITH BILLIARD ROOMS

NOTE: MANAGER'S AUTOMATIC PINSETTER CONTROL BOX (LOW VOLTAGE) ONE PER EVERY EIGHT LANES. 11" WIDE \times 8 $\frac{3}{4}$ " LONG \times 4 $\frac{3}{4}$ " DEEP. SUPPLIED BY BRUNSWICK - INSTALLED BY CUSTOMER. CONTROL SWITCH UNITS FOR TEL-E-SCORE, TEL-E-FOUL, MASKING UNIT LIGHTS, APPROACH & LANE LIGHTING, EXTERIOR SIGNS ETC., TO BE SUPPLIED AND INSTALLED BY CUSTOMER. INTERCOM & TELEPHONE EQUIPMENT SUPPLIED AND INSTALLED BY CUSTOMER.

Fig. 9 Typical control desk.

BOWLING ALLEYS WITH BILLIARD ROOMS

cases, open locker rooms use carpeted floors instead of tile or terrazzo.

Washrooms Public toilets are areas of heavy traffic and require constant cleaning. Since they receive constant inspection by the public, they must be kept immaculate.

The entry to any public toilet must be screened to ensure privacy.

In some areas, the law requires a couch or lounge in public rest rooms for ladies. Mirrors are required in all rest rooms.

Janitor's Closet The janitor's closet should contain a slop sink and storage area for general cleaning supplies and vacuum as well as floor polishers, lane dusters, gutter mops, lane maintenance machines, etc.

It should be located close to the front of the lanes, usually off the concourse, and should be ventilated to the outside.

An adequate size janitor's closet, minimum 4 by 6 ft; 6 by 8 ft preferred, is an asset to maintenance.

Manager's Office Most establishments of 16 lanes or over, and many smaller installations, provide an office facility. It is used by the manager and bookkeeper to perform necessary routine clerical duties such as material ordering and record keeping. The office should be under the supervision of the control, check-room, or pro shop.

The office should be well lighted, 75 to 100 footcandles. A private toilet facility for the office is not normally provided; if public toilets are not clean enough for the manager, they are not suitable for the customer.

Snack Bars Generally, the snack bar is the only food-handling facility in the bowling establishment.

Except in circumstances that show complete justification, a complete restaurant operation is not recommended, since experience shows that a restaurant operation normally does not show profit on the same scale per square foot as the other functions in the building. The exceptions to this rule might be local areas where the restaurant is required for a

bar or liquor license, or local areas where the success of such a restaurant is assured independently of the bowling trade.

In any food-handling operation, the keynote to success is experience in the business. Such experience will point the way to efficient layout of space and equipment.

As a rule, snack bars should be brightly illuminated and decorated in lively, bright colors conducive to food consumption. Maintenance of walls and ceilings, as well as floors, counters, and equipment, is of prime importance; and the careful selection of these materials is mandatory.

Air conditioning and exhaust of cooking odors require very careful planning.

Automatic fire extinguishing systems should be installed over grills and deep-fat fryers and in hood and duct assembly. This will provide maximum safety.

Bars and Cocktail Lounges In the majority of installations, the bowling center bar (or bars) functions for the convenience of bowlers and is not intended to rely on street traffic as a normal tavern must.

The location of the bar within the bowling center is of prime importance and is related to local laws, traffic flow, and drinking habits of bowlers in the local area. If bowlers usually enjoy alcoholic beverages while bowling, a simple quick-service bar may be indicated in addition to the cocktail lounge. In bowling centers too large to be serviced by a single bar, a service bar or quickie bar on the concourse can furnish soft drinks, beer, or highballs convenient for waitress service to the lanes or for consumption at the quick-service bar. Cocktails or fancy mixed drinks would be available only at the cocktail bar. Sometimes a service bar or quickie bar requires a special license.

The decor of cocktail lounges and bars runs the gamut of interior decorating. It can be as plush or as simple as the owner decides. It may have live entertainment and it may even double as a restaurant facility. Bar size and seating capacity may be governed by local or state ordinances.

Normally in planning, consideration is given

Fig. 10 Billiard table and spacing dimensions.

to some food service in the cocktail bar, if only short-order sandwiches. For this reason it is wise to locate the bar close to either the kitchen or snack bar.

Often the meeting room facility is an extension of the cocktail lounge, which can be easily screened off by use of a folding door for private functions. Toilet facilities, separate from the bowling toilets and lockers, are frequently provided for the convenience of bar patrons. Often these facilities are required by law locally.

State and municipal ordinances govern, to a large degree, the construction of walls and entrances for places where alcoholic products are sold and/or consumed.

Private "key club" operations are sometimes allowable where public bars are prohibited.

Provisions must be made for storage areas for supplies. Liquor storage should be locked. Beer requires supply storage (cases may be stacked), precooling, and an empty bottle sorting and storage area. Often a conveyor chute is used to remove empty bottles from the bar to sorting and storage areas. Easy access from the street to the storage areas is necessary for delivery of supplies.

Recreation and Entertainment

SWIMMING POOLS

Minimum standards prepared by the National Swimming Pool Institute

PUBLIC SWIMMING POOLS

DEFINITION AND POOL TYPES

1. All artificially constructed swimming pools other than residential pools shall be deemed to be public swimming pools. This shall not be applicable to residential pools as defined or wading or spray pools, which shall be covered under separate sections.

(a) **Private pools** which are excepted herein shall be defined as follows: "Residential swimming pools include all constructed pools which are used or intended to be used as a swimming pool in connection with a single-family residence and available only to the family of the householder and private guests."

(b) **Classifications of Pools:** For purposes of minimum standards, public swimming pools shall be defined as listed in the following categories, based upon specific characteristics of size, usage and other factors:

Type "A"—Any municipal pool, community pool, public school pool, athletic or swimming club pool.

Type "B"—Institutional pool (such as Girl Scout, Boy Scout, YMCA & YWCA, Campfire Girls and Boys' and Girls' Camps).

Type "C"—Country Club, large hotels of more than 100 units, with pools having a water surface area in excess of 1600 sq ft.

Type "D"—Motels and apartments, multiple housing units, small hotels of less than 100 units, not open to the general public and with pools having a water surface area not larger than 1600 sq ft.

Type "E"—Treatment pools, therapeutic pools and special pools for water therapy.

Type "F"—Indoor pools.

Exceptions: The above categories shall be the basis for certain specific variations from the Minimum Standards for public swimming pools as a whole.

NOTE: plans and specifications with supporting data, prepared by a professional

engineer or architect holding registration in the state where pool is to be constructed, shall be, as a prerequisite, submitted to and approval obtained from said state regulator agency prior to award of any contract for equipment purchase or construction.

STRUCTURAL FEATURES, MATERIALS, MARKINGS

2. **Structural Stability:** All public pools shall be constructed of an inert and enduring material, designed to withstand all anticipated loading for both pool empty and pool full conditions. Working stresses shall be based upon predetermined ultimate strengths of materials used, with a factor of safety of not less than 2½.

Provision shall be made for the relief of pressures which might occur as a result of unbalanced exterior hydrostatic pressures, or means shall be provided for positive and continuous drainage from under the pool floor or around the pool walls, whether

ground water is present, or might occur at some future time.

Special provisions shall be made to protect the pool structures from both internal and external stresses which may develop due to freezing in cold climates.

3. **Obstructions:** There shall be no obstruction extending from the wall or the floor, extending into the clear area of the diving portion of the pool. There shall be a completely unobstructed clear distance of 13 ft above the diving board.

4. **Wall & Floor Finish:** Wall and floor finish shall be of masonry, tile or other inert and impervious material and shall be reasonably enduring. Finish shall be moderately smooth and of a white or light color.

5. **Depth Markers:** Depth of water shall be plainly marked at or above the water surface on the vertical pool wall and on the edge of the deck or walk next to the pool, at maximum and minimum points

The technical data presented here gives basic requirements for public and semi-public pool design, systems and equipment. It is intended by the NSPI to serve as recommended minimum standards, and not as a model code.

STANDS & BOARDS		Depth—Feet & Inches					Length of Section—Feet & Inches					
		D-1	D-2	D-3	D-4	D-5	A	B	C	D	E	F
3-Meter Board	Min.	5-0	4-6	10-0	9-9	8-6	5-0	*6-0	*9-0	20-0	1-0	8-0
	Max.		5-6				6-0	10-0				
1-Meter Board	Min.	5-0	4-6	8-6	8-3	7-6	5-0	*6-0	*9-0	15-0	1-0	8-0
	Max.		5-6				6-0	10-0				
Deck Level Board	Min.	5-0	4-6	8-0	7-6		2-6	†6-0	†6-0	12-0	1-0	8-0
	Max.		5-6				4-0	10-0				

As D-2 varies between min. and max., D may vary, but slope of D may not exceed 1 ft vert. to 4 ft horiz. D-1 shall be at end wall of diving area, or not more than 12 in. from it

* B & C May vary to attain 15'-0" Min.
† B & C May vary to attain total 12'-0" Min.

SWIMMING POOLS

and at the points of break between the deep and shallow portions and at intermediate increments of depth, spaced at not more than 25 ft intervals. Depth markers shall be in numerals of 4 in. min. height and of a color contrasting with background. Markers shall be on both sides and ends of the pool.

6. Lifeguard Chairs: Each public swimming pool shall have at least one elevated lifeguard chair. This shall be presumed to be adequate for 2,000 sq ft of pool surface area and one additional lifeguard chair shall be provided for each additional area of 2,000 sq ft or fraction thereof. Where a pool is provided with more than one lifeguard chair and the width is 40 ft. or more, they shall be located on each side of the pool. In Types D & E pools, lifeguard chairs need not be provided.

7. Life Line: A life line shall be provided at or near the break in grade between the shallow and deep portions of a public swimming pool, with its position marked with colored floats at not greater than 5 ft spacing. Life line shall be not less than $\frac{3}{4}$ in. min. dia.; its terminals shall be securely anchored and of corrosion-resistant material and of type which will be recessed or have no projection which will constitute a hazard.

8. Ladders: A minimum of one ladder shall be provided for each 75 ft of perimeter and not less than two ladders shall be provided at any pool. Where stairs are provided in a pool, one ladder may be deleted for each set of stairs provided. A side hand-rail extending up above and returning to the horizontal surface of the pool deck, curb or coping shall be provided at each side of each ladder.

All stairs entering a public pool shall be recessed. An exception to this may permit the construction of steps directly entering the pool and not recessed into the pool walls, in Types C, D, & E.

POOL DIMENSIONS, WALKS, FENCES

9. Shallow Minimum Depth: Every public swimming pool shall have a minimum depth in the shallow area of the main swimming area of not less than 3 ft, nor more than 3 ft 6 in. from the overflow level to the floor. Exceptions may be made for Types B, C, D & E pools, or in pools built principally for instruction, or in a recessed area of the main swimming pool where pool

is of an irregular shape such as the leg of a T, L or Z.

10. Shallow Area: In a swimming pool with a diving area, the shallow portion of the pool shall be defined as the portion between the shallow end and the break point between the shallow area and the diving area. The slope of the floor shall be uniform from the break between the diving area and the shallow portion to the outside edge of the shallow portion and shall not be greater than 1 ft of slope in 12 ft, except in small Type B pools where the pool is less than 42 ft in overall length, in which case the rate of slope shall not exceed 1 ft in 8 ft.

11. Diving Area: The area of a public swimming pool where diving is permitted shall be, in the case of a rectangular pool, at one end, or may be in a recessed area forming one of the legs of a T, L or Z shaped pool, divorced from the main swimming area by a life line, or may be a wholly separate pool structure. Exceptions to this may be made in special-purpose type pools intended for training and instruction.

Pools of the types wherein diving is permitted shall have adequate area and depth of water for safe diving and the minimum depth and area characteristics for this area shall be as indicated in the accompanying chart.

12. Diving Towers: Diving towers in excess of 3-meters in height shall not be considered as acceptable in a public pool without special provisions, controls and definite limitations on their use.

13. Vertical Wall Depth: As a minimum, the pool walls shall be vertical at all points for a depth of not less than 2 ft 6 in.

14. Walks: Walks shall be continuous around the pool with a minimum width of 8 ft of unobstructed clear distance including a curb at the pool edge, if such a curb is used. Exceptions may be made in Types B, C, D, E, & F as follows: B—4 ft; C—4 ft; D—4 ft; E—No minimum; F—4 ft.

A minimum of a 3 ft walk width shall be provided on the sides and rear of any piece of diving equipment.

All walks, decks and terraces shall have a minimum slope of $\frac{1}{4}$ in. per foot to drains or points at which the water will have a free unobstructed flow to points of disposal at all times.

The finish texture of walks must be non-slip and such that there will be no discomfort to bare feet.

Hose bibbs shall be provided around the perimeter of the deck area at intervals such that all parts of the swimming pool deck area may be reached with a 50 ft hose.

15. Fence: A wall or other enclosure of 4 ft minimum height and with maximum 2 in. mesh, 2 in. wide vertical openings, or otherwise so constructed as to be difficult to climb, shall be provided completely enclosing the pool area, all of which shall be paved.

Exceptions may be made for Types C & D

In Types C & D where the fence is dispensed with, a hedge or other clear demarcation shall be provided, with instructions and posting clearly defining the pool area as for bathers only and from which spectators and others in street clothes are rigidly excluded.

Access to the pool by bathers shall be provided only through the bathhouse or dressing room facilities, and any other fence opening shall be for service operations only.

GUTTERS AND SKIMMERS

16. Overflow Gutters: An overflow gutter shall be installed continuous around all public swimming pools, with the exception that it may be eliminated in Types B, C, D & E. The overflow gutter may be eliminated across the top tread where steps occur.

Overflow gutter shape, wherein the outer edge of the lip is flush with the pool wall above and below and the gutter entirely recessed, shall not be permitted.

The overflow gutter depth below the overflow lip shall be a minimum of 2 in. at the high points between drains. The drains shall be spaced at a maximum of 15 ft on centers and a slope provided in the bottom of not less than $2\frac{1}{2}$ in. in 10 ft. In no sense is this intended to preclude the use of roll-out or deck level type pools where other conditions are met and satisfactory design is provided. In an installation where the overflow gutter is not carried to waste but is a part of the recirculation system, the provisions of spacing of drains and slope at bottom of gutter may be modified but shall conform to good hydraulic design.

The branch piping to each overflow gutter drain shall be not less than 2 in.

SWIMMING POOLS

Where overflow gutter drains discharge into sanitary sewers, a trap shall be provided in each main before discharge into the sewer.

The overflow gutter mains shall have a sufficient minimum size and be increased as necessary to carry the overflow water freely with a maximum of 2 ft pressure head or surcharge, at all times.

Where overflow gutters discharge into a sanitary sewer or storm sewer, an air-gap of not less than 1 ft shall be provided between the point of discharge of the gutter and the drains into the sewer, or a relief manhole shall be provided where surcharge or back pressure will overflow at a point not less than 12 in. below the elevation of the overflow gutter fittings in the gutter.

Disposal of water from the overflow gutters may be either to waste or may enter the circulation system and be filtered and returned to the pool.

17. Surface Skimmers: Skimmers may be permitted in lieu of overflow gutters on swimming pools of Type B, C, D & E, providing acceptable handhold is installed. At least one skimming device shall be provided for each 800 sq ft of surface area or fraction thereof. The handhold must be no more than 9 in. above the normal water line. Skimming devices shall be built into the pool wall, shall adequately remove floating oils and waste and shall meet the following general specifications:

(a) Each skimmer shall be designed for a flow-through rate of at least 30 gallons per minute and the total capacity of all skimmers in any pool shall be approximately 50% of the required filter flow of the recirculation system.

(b) They shall be automatically adjustable to variations in water level over a range of at least 3 in.

(c) An easily removable and cleanable basket or screen through which all overflow water must pass shall be provided to trap large solids.

(d) The skimmer shall be provided with a device to prevent airlock in the suction line. If an equalizer pipe is used, it shall provide an adequate amount of makeup water for pump suction, should the water of the pool drop below the weir level. This pipe shall be at least 2 in. in diameter and shall be located at least 1 ft below the lowest overflow level of the skimmer.

(e) An equalizer line shall be provided with a valve that will remain tightly closed under normal operating conditions, but will automatically open at a differential of not more than 4 in. between the pool level and the level of the overflow tank.

(f) The overflow weir shall be of sufficient length to maintain a rate of flow of at least 20 gallons per minute per lineal foot of weir lip.

(g) Skimmer shall be of substantial, enduring and reasonably corrosion-resistant material.

One skimmer will be placed at a point in the pool opposite the direction of prevailing summer winds.

FILTRATION

18. Recirculation and Filtrations: All public swimming pools shall have recirculation and filtration equipment provided for water purification in accordance with criteria in this report.

19. Filters, Sand: These minimum standards shall apply, where applicable, to either gravity or pressure sand filters.

Filter tanks shall be designed with a factor of safety of 4 in relation of working pressure to ultimate strength.

The filter bed shall consist of suitable grades of filter sand and a supporting bed of graded gravel or other porous material which shall serve to support the filter bed and distribute both filtered and backwash water uniformly. The supporting bed consisting of graded gravel or other material shall support not less than 20 in. of filter media consisting of silica sand or other durable, inert material with an effective size between 0.4 and 0.55 mm, and a uniformity coefficient not exceeding 1.75.

The minimum freeboard to the draw-off point shall be not less than 12 in. above the normal level of the top of the filter bed. The minimum backwash rate shall be not less than 12 gallons per square foot of filter bed per minute.

Where anthracite coal or other filter media is employed, the freeboard shall be adequate to prevent the media being carried off to waste when the filter bed is backwashed at a rate adequate to carry off foreign material filtered from the water. The freeboard and the rate of backwash

shall be the subject of individual design, based upon specific gravity of the media.

Under-drain system shall be such that uniform distribution of backwash water shall be provided over the entire bed area.

Ratio of total under-drain orifice area to total area of bed shall be not less than 0.25 per cent.

Orifices in the under-drain system shall be spaced at approximately 6 in. on centers both ways throughout the area of filter bed. The total orifice area may be provided by means of porosity of the material over the total under-drain area.

Under-drain system shall be provided of material which is corrosion-resistant and enduring, wherein the orifices shall be so designed and of such material that they will maintain approximately constant area.

Where the under-drain system is of manifold and lateral type, the total area of the manifold shall be equal to not less than the total area of the laterals. The total area of the laterals shall be not less than 1¼ times the total area of the orifices.

Design rate for sand filters shall be 3 gallons per minute, per square foot of bed area, as a minimum standard.

The filter plant shall be provided with influent and effluent pressure gauges, backwash sight glass and air-relief valves.

The filter plant shall be provided with face piping and valving to permit the functions of filtering to pool or backwashing to waste with the battery as a whole or any unit operated singly.

The filter plant shall be provided with means for draining all filter units and piping, so that all parts of the system may be completely drained to prevent damage from freezing.

Each filter unit shall be provided with an access opening of not less than a standard 11 in. by 15 in. manhole and cover.

Pressure filter tanks shall be supported by jack legs or other supports to give a free movement of air under each tank and to permit access for painting.

Filter turn-over cycle shall be of capacity to completely filter the entire pool body in not more than 8 hours.

SWIMMING POOLS

20. Filters, Diatomite: Where diatomite filters are used, they may be of either pressure or vacuum type. The filter rate shall not exceed 2.5 gpm per square foot of filter surface area.

The cycle of operation between cleaning of the diatomite filters shall be not less than a 24 hr period of continuous operation and this shall not be deemed to apply to initial operation of a pool, but only after operation for a period of 3 days or such period as is necessary to initially clear the pool.

Provisions shall be made to introduce a pre-coat to completely cover the filter elements, upon placing the equipment in initial operation and/or after each cleaning. The equipment shall be so arranged that during pre-coating, the effluent will be re-filtered or disposed to waste without passing into the pool until the effluent is clear of suspended matter.

Equipment shall be provided for the continuous feed of filter aid to the filter influent and the equipment shall have a capacity to feed not less than 0.1 lb of this material per square foot of filter area over a 24 hour period.

Exceptions to the above may be made in Types B, C, D, E & F pools, in cases where this equipment need not be provided.

The tank containing the diatomite filter elements shall be constructed of intermediate carbon steel, plastic or other suitable material which will satisfactorily provide resistance to corrosion, with or without coating, and shall be of adequate strength to resist all stresses resulting from loading with a factor of safety of 4, in relation to the ultimate strength.

The septum or elements which support the filter aid shall be of corrosion-resistant material and shall be provided with openings, the minimum dimension of which shall be not greater than 0.005 in.

The septa shall be constructed to be adequately resistant against crushing or deformation, with the maximum differential pressure between influent and effluent of not less than the maximum pressure which can be developed by the circulating pump and of adequate strength to resist the stresses developed by the cleaning operation, with the impact developed from an accelerated washing operation.

In the complete filter installation, where dissimilar metals are used which may set

up galvanic electric currents, the metals shall be insulated with a suitable dielectric which will satisfactorily prevent corrosion from electrolysis.

The filters shall be designed and installed in such a manner that they can be readily disassembled and elements removed and they shall not be installed where inadequate working space above or around is available for such disassembling.

The filter plant shall be provided with pressure differential gages and air-relief outlets where necessary.

21. Filters, Other: In the absence of complete information on operating characteristics, durability, etc., of cartridge and other type filters, no minimum standards can be established at this time and their installation on public pools may only be made on a trial basis.

22. Compound Gauge: The pump suction header shall be provided with a compound gauge between the pump strainer and the pump, which will indicate both positive and negative head.

23. Strainers: At all pressure type filter plants or where the circulating pump is used for vacuum cleaning the pool, a suitable strainer or screen shall be provided to remove solids, debris, hair, lint, etc. Where a wet well is provided, the strainer shall consist of a removable screen through which all water entering the pump shall pass. Where no wet well is provided or where the suction cleaner or any other suction line is piped directly from the pool to the pumps, a pot-type strainer with removable strainer basket shall be provided. The strainer basket shall be of rigid construction sufficiently strong to prevent collapsing when clogged. One extra strainer basket shall be provided.

Any type of screen or strainer basket shall be fabricated of a corrosion-resistant material or shall have a protective coating of such material.

Screen or strainer basket shall have maximum openings no greater than $\frac{3}{4}$ the size of the solids which will pass through the pump impeller without clogging and the total clear area of all openings shall be not less than 4 times the area of the largest sized pipe from the pool to the strainer influent.

24. Rate-of-Flow Indicator: Every swimming pool provided with recirculation and

refiltration system shall be provided with a rate-of-flow indicator on the pump discharge line leading to the filters and shall be calibrated for measuring both water for filtration and backwash and the activating element creating the pressure differential for indication of flow shall be installed with adequate clear distance upstream and downstream to obtain a reasonable degree of accuracy.

The rate indicator shall be calibrated for and provided with a scale reading in gallons per minute and shall have a range of 10% below the established filtration rate and 10% above the backwash rate established.

Where diatomite filters are used, the activating element of the flow indicator shall be installed in the filter effluent line.

POOL POPULATION, SANITARY FACILITIES

25. Capacity of Pool in Bathers: The maximum number of persons in bathing attire within the pool enclosure or the bathing area shall be limited to one person per 20 sq ft of pool and deck area combined.

26. Bathhouse: Adequate dressing and sanitary plumbing facilities shall be provided for every public swimming pool. An exception to this may be made in Types B, C, D, E & F pools where available facilities are provided in connection with the general development for other purposes, etc., of adequate capacity and number, in close proximity to the pool.

Every bathhouse shall be provided with separate facilities for each sex with no inter-connection between the provisions for male and female. The rooms shall be well-lighted, drained, ventilated and of good construction, with impervious materials employed in general, finished in light colors and so developed and planned that good sanitation can be maintained throughout the building at all times.

(a) Minimum sanitary plumbing facilities shall be provided as follows:

Males: One water closet combination, one lavatory and one urinal shall be presumed to be adequate for the first 100 bathers.

One water closet and one urinal shall be provided for each additional 150 bathers or major fraction thereof. One lavatory shall be provided for each 200 additional bathers.

Recreation and Entertainment

SWIMMING POOLS

A minimum of three shower heads shall be provided which shall be presumed to be adequate for the first 150 males and one shower outlet shall be provided for each additional 50 male bathers.

Females: A minimum of two water closet combinations shall be provided in each bathhouse building and this shall be presumed to be adequate for the first 100 females.

One additional water closet combination shall be provided for each additional 75 females or fraction thereof.

A minimum of two shower heads shall be provided, which shall be presumed to be adequate for the first 100 females and one shower shall be added for each 50 additional females.

One lavatory shall be provided as a minimum, which shall be considered adequate for the first 75 females. One additional lavatory shall be provided for each additional 75 females in attendance, or major fraction thereof.

These minimum criteria for bathhouse plumbing facilities shall be based upon the anticipated maximum attendance in bathers. Facilities for either sex shall be based upon a ratio of 60% of the total number of bathers being male and 40% being female.

Shower and dressing booths shall be provided in female dressing space and dressing booths shall be provided with curtains or other means of seclusion. This condition may be subject to variation for schools and other institutional use where a pool may be open only to one sex at a time.

(b) *Drinking Fountain:* Not less than one drinking fountain shall be provided available to bathers both at the pool and in the bathhouse.

(c) *Hose Bibbs:* Hose bibbs shall be provided for flushing down the dressing rooms and bathhouse interior.

The floors of the bathhouse shall be concrete, free of joints or openings and shall be continuous throughout the area with a very slight texture to minimize slipping but which shall be relatively smooth to ensure complete cleaning. Floor drains shall be provided to ensure positive drainage of all parts of the building with a slope in the floor of not less than $\frac{1}{4}$ in. per foot, toward drains.

(d) *Hot Water:* Heated water will be provided at all shower heads. Water heater and thermostatic mixing valve shall be inaccessible to bathers and will be capable of providing 2 gpm of 90 F. water to each shower head, and no other water shall be supplied.

No differences in elevation, requiring steps, shall be provided in the interior of male and female dressing areas. No steps shall be permitted between the bathhouse and the pool deck areas adjoining and should it be necessary that the bathhouse floor be at a different elevation from the pool decks, ramps shall be provided at the access doors. Where ramps are used between the bathhouse and pool decks, the slope shall not exceed 3 in. per ft and shall be positively non-slip.

All partitions between portions of the dressing room areas, screen partitions, shower, toilet and dressing room booths shall be of durable material not subject to damage by water and shall be so designed that a water way is provided between the partitions and floor to permit thorough cleaning of the floor area with hoses and brooms.

(e) *Soap dispensers:* Soap dispensers for providing either liquid or powdered soap shall be provided at each lavatory and between each pair of shower heads and dispensers must be of all-metal or plastic type and no glass permitted in these units.

(f) *Mirrors:* Mirrors shall be provided over each lavatory and toilet paper holders shall be provided at each water closet combination.

(g) *Water:* All water provided for drinking fountains, lavatories and showers shall be potable and meet the requirements and conform with the standards of the U. S. Public Health Service.

27. Food Service: Where provision is made for serving food and/or beverages at the pool, no containers of glass or other material which might be a hazard to bathers' feet, when broken, shall be used. The area shall be so arranged and posted to prohibit the consumption of food and beverages on the pool decks proper.

ELECTRICAL REQUIREMENTS

28. Lighting and Wiring

(a) *Submarine Lighting:* Where submarine lighting is used, not less than 0.5 watts shall be employed per square foot of pool area.

(b) *Area Lighting:* Where submarine lighting is employed, area lighting shall be provided for the deck areas and directed toward the deck areas and away from the pool surface insofar as practical in a total capacity of not less than 0.6 watts per square foot of deck area. Where submarine lighting is not employed and night swimming is permitted, area and pool lighting combined shall be provided in an amount of not less than 2 watts per square foot of total area.

(c) All wiring in connection with requirements for a swimming pool for lighting or power shall conform with the codes of the National Underwriters' Laboratories (National Electric Code).

(d) In addition to any other grounding, each submarine light unit shall be individually grounded by means of a screwed or bolted connection to the metal junction box from which the branch circuit to the individual light proceeds.

(e) *Overhead Wiring:* No electrical wiring for lighting or power shall be permitted to pass overhead within 20 ft of the pool enclosure.

DRAINAGE PIPING

29. Mechanical Pool Fittings: Where overflow gutters are installed, outlet spacing shall not be greater than 15 ft on centers.

Overflow gutter branch lines from each drain fitting shall be not less than 2 in. I.P.S.

Pool inlets and outlets shall be provided and arranged to produce a uniform circulation of water and the maintenance of uniform chlorine residual throughout the pool; there shall be at least four inlets for the smallest pool.

Provisions shall be made to adjust the flow through all inlets.

Maximum flow rates (in gpm) through various sized inlet branches shall be not more than as follows: Size & gpm; 1 in. = 10; $1\frac{1}{4}$ in. = 20; $1\frac{1}{2}$ in. = 30; 2 in. = 50.

In pools with surface area greater than 1500 sq ft or length in excess of 60 ft, inlets shall be placed around the entire perimeter. In any case, an adequate number of inlets shall be provided, properly spaced and located to accomplish complete

SWIMMING POOLS

recirculation and the maintenance of a uniform and adequate sterilizing medium at all times.

30. Main Drain Spacing: When the outlets to pool pump suction are installed near the end of a pool, the spacing shall be not greater than 20 ft on centers. An outlet shall be provided not more than 15 ft from side wall.

The outlet grate clear area shall be such that when the maximum flow of water is being pumped through the floor outlet, the velocity through the clear area of the grate shall not be greater than $1\frac{1}{2}$ ft per second. Outlet grates shall be anchored and openings in grates shall be slotted and the minimum dimension of slots shall be not more than $\frac{1}{2}$ in.

Where outlet fittings consist of parallel plates, of so-called anti-vortex type where the water enters the fittings from the sides rather than through a grating facing upward, entrance velocities may be increased to 6 ft per second.

All pool fittings shall be of non-corrosive material.

31. Piping: The determination of sizes of pipe, fittings and valves on the complete main pump suction line from the swimming pool shall be based upon a rate of friction losses for piping of not more than 6 ft per 100 ft of pipe, based upon Hazen-Williams formulas for 15-year old piping.

All piping on the discharge side of the pump for filtration and to the point for discharge of backwash water from the filter plant shall have pipe sizes determined on a basis of friction losses which shall be not more than 12 ft per 100 ft and the velocity in any pipe shall not exceed 10 ft per second and pipe selection shall be made based upon Hazen-Williams formulas for 15-year old pipe. In the determination of pipe sizes required, the criterion which would call for the largest pipe size shall govern.

All pool piping shall be supported by piers or otherwise to preclude against possible settlement which will either provide dirt traps or air pockets and a condition which would result in rupture of the lines.

All pressure and suction lines shall have a uniform slope in one direction of not less than 3 in. per 100 ft. Gravity waste lines around the pool 6 in. or smaller shall have a minimum slope of $\frac{1}{8}$ in. per ft. Lines larger than 6 in. and all outfall waste mains shall be designed with a size of pipe

and slope to freely carry the maximum flows required with no surcharge or back pressure in the lines. All piping and equipment shall be provided with positive means of completely draining all water to prevent damage from freezing.

32. Direct Connections to Utilities: No direct mechanical connection between a source of domestic water supply shall be made to a swimming pool or to its piping, thereby eliminating a cross connection to what may become a source of contamination.

The water supply for filling the pool, when derived from a potable supply, shall be by means of an over-fall fillspout to the pool, or an over-fall supply to a surge tank, wherein the water will freely overflow at deck level or the top of the surge tank, before coming into contact with the water supply outlet.

The disposition of sanitary sewage from the bathhouse shall be into a sanitary sewer, a septic tank or other waste line which meets with the approval of local health authorities.

Whenever any waste from the swimming pool is connected to a sanitary sewer or a storm sewer, an air-gap or a relief man-hole shall be provided which will positively preclude against surge or backflow introducing contaminated water into the swimming pool or the water treatment plant as covered elsewhere.

33. Pump and Motor: Pump and motor unit shall be provided for recirculation of the pool water which has been selected for performance and will meet the conditions of quantity required for filtering and cleaning the filters with the total dynamic head developed by the complete system. The requirements for filtration shall be based upon the maximum head loss developed immediately prior to washing the filters. The motor shall be non-overloading in continuous operation for filtration under all conditions but may be overloaded within the service factor for conditions of backwash and for emptying the pool.

Pump performance curve for the unit to be installed shall be provided and submitted to proper authorities.

34. Vacuum Cleaner: Where facilities are installed integrally in the pool piping system for the operation of a vacuum cleaner, the piping shall be required to produce not more than 15 ft total head loss at the pump,

while moving four gallons per minute per lineal inch of cleaner head.

35. Sterilizing Agent: Some means of sterilizing the pool water shall be used which provides a residual of sterilizing agent in the pool water. Either chlorine or bromine may be used for this purpose. In either case, adequate feeding equipment and equipment for testing residuals must be employed. Inasmuch as chlorine is almost universally used, minimum standards for the use of chlorine are given below.

In all public pools, chlorine shall be supplied by means of a gas chlorinator which controls and introduces the chlorine gas into water solution and introduces it into the pool water. Exceptions to this may be made in Types B, C, D, E & F swimming pools, where chlorine may be applied in the form of hypochlorites fed by a positive feed pump suitable for use with hypochlorite in solution.

Equipment for supplying chlorine or compounds of chlorine shall be of capacity to feed 1 lb of available chlorine per 3000 gallons of pool volume per 24-hour period. This may be reduced by 50% for Type E pools.

36. Instructions: All valves shall be permanently tagged and valve operating schedule shall be provided for every operation. Instructions shall be supplied in not less than two copies.

POOL WATER AND TREATMENT

37. Chlorine Compartment: Where gaseous chlorine equipment is provided below grade in a filter room or in any part of a building which provides housing, the mechanical proportioning device and cylinders of chlorine shall be housed in a reasonably gas-tight corrosion-resistant and mechanically vented enclosure. Air-tight duct from the bottom of the enclosure to atmosphere in an unrestricted area and a motor-driven exhaust fan capable of producing at least one air change per minute shall be provided. Automatic louvers of good design near the top of the enclosure for admitting fresh air are required. An opening at least 18 in. square, glazed with clear glass, and artificial illumination shall be provided in an amount such that the essential performance of the equipment may be observed, at all times, without opening the enclosure. Electrical switches for the control of artificial lighting and ventilation shall be on the outside of the enclosure adjacent to the door. The floor area of the enclosure shall

SWIMMING POOLS

Diving Pools

be of adequate size to house the chlorinator, fan, scales and one extra chlorine cylinder. Gas mask approved by the Bureau of Mines for protection against chlorine gas shall be provided, mounted outside the chlorine compartment.

33. Coagulant Feeder: Coagulant feeder of cast-iron pot type with piping arranged to provide a restriction in the flow or other means of creating a pressure differential which will circulate a portion of the filter influent on a ratio proportionate to the rate of flow shall be provided. Pot shall be of good grade gray cast iron with quick-removable, tight-gasketed cover and will be piped with IPS brass pipe to circulate through the feeder with a tapping at the bottom of the feeder for entering water and a tapping at the top for supplying coagulant solution to the filter influent. Control valves, one of which shall be needlepoint type, and a drain cock for draining the equipment when the plant is out of operation shall be provided. The capacity of the pot shall be not less than 2 oz of lump or nut potassium alum per square foot of filter bed area.

39. Testing Equipment: A test set shall be provided for the determination of free chlorine residual and the pH hydrogen-ion content in the pool water of colorimetric type with test tubes and supply of phenol red solution and orthotoluidine agents.

Color standards shall be as follows and the carrying case and test tubes shall be provided of plastic or other material which is permanent and unbreakable:

Chlorine color standards—0.1, 0.3, 0.6, 0.8 ppm; pH color standards—6.8, 7.2, 7.6, 8.0

40. Quality of Water: The equipment when operated in accordance with the manufacturer's instructions, shall provide water meeting the following standards:

(1) Shall meet U.S. Public Health Service requirements for bacteriologically potable water.

(2) Shall have a degree of clarity such that a disc 2 in. in diameter which is divided into quadrants in alternate colors of red and black shall be clearly discernible through 15 ft of water and the different colors readily distinguishable.

(3) Shall have a minimum free available chlorine residual at any point in the pool of not less than 0.25 ppm and not more than 1.0 ppm at any time.

(4) The pH or measure of hydrogen-ion content at no time shall be below 7.0 and shall be maintained between this limit and 8.0 on the hydrogen-ion scale.

41. Pool Temperature: Temperature of indoor pools shall be maintained between 75 and 85 F., with exceptions made in Type E pools.

WADING POOLS

By definition, a wading pool shall normally be a small pool for non-swimming children, only, used only for wading and shall have a maximum depth at the deepest point not greater than 24 in.

Owing to the high degree of pollution likely to be present, a wading pool shall have a maximum turn-over cycle of 4 hours. The supply to the wading pool shall consist of filtered and chlorinated water from the large pool filtration and recirculation system. The circulating outlets from the wading pool may be wasted or may be returned to the circulation system of the large pool at the suction side of the pump for re-filtration. Also a waste outlet shall be provided at the deepest point of the wading pool, by means of which it shall be completely emptied to waste.

In general, standards of sanitation in circulation, surface skimming and all other details shall be equal or superior to those for swimming pools. It is considered to be very desirable to install a spray pool in lieu of a wading pool, wherein no water stands at any time but is drained away freely as it sprays over the area.

By R. JACKSON SMITH, AIA, Eggers and Higgins, Architects

DIVING POOLS

Separation of swimming and diving pools has long been common practice abroad and is an increasing trend in the United States. Diving does not require a very large pool, but it must be deep—at least 14 ft below a 10-meter platform. A swimming pool must be large in area, but it need be no more than 4 or 5 ft deep and can have a flat bottom.

Olympic requirements for diving pools are shown in the accompanying diagram and table. Minimum requirements can be met with a pool 35 by 45 ft, but a somewhat larger size, e.g., 60 by 60 ft, is usually advisable. A water-curling arrangement should be provided so that the diver can see exactly where the surface of the water is. If outdoors, the pool should be oriented so that the sun is not in the diver's eyes. Underwater observation ports are desirable.

Diving pool and platform dimensions for competitive swimming

	Board size		Ht. above water level	Distances*			
	Length	Width		A From edge of pool to end of board	B From center of board to side of pool	C From center of board to center of board	D From end of board to wall ahead

SWIMMING POOLS

Residential Swimming Pools

Minimum standards prepared by the National Swimming Pool Institute

RESIDENTIAL SWIMMING POOLS

The technical data presented here give basic requirements for residential swimming pool design, systems and equipment. It is intended by the NSPI to serve as recommended minimum standards and not as a model code.

DEFINITIONS AND NOMENCLATURE

- 1. Swimming Pool**—Any constructed pool, used for swimming or bathing over 24 in. in depth, or with a surface area exceeding 250 sq ft.
- 2. Residential Swimming Pool**—Any constructed pool which is used, or intended to be used, as a swimming pool in connection with a single family residence.
- 3. Main Outlet**—The outlet(s) at the deep portion of the pool through which the main flow of water leaves the pool.
- 4. Main Suction**—The line connecting the main outlet to the pump suction.
- 5. Vacuum Fitting**—The fitting in the wall of the pool which is used as an outlet for connecting the underwater suction cleaning equipment.
- 6. Vacuum Piping**—The piping which connects the vacuum fitting to the pump suction.
- 7. Return Piping**—The piping which carries the filtered water from the filter to the pool.
- 8. Inlet**—The fitting or opening through which water enters the pool.
- 9. Face Piping**—The piping with all valves and fittings which is used to connect the filter system together as a unit.
- 10. Recirculating Piping**—The piping from the pool to the filter and return to the pool, through which the water circulates.
- 11. Backwash Piping**—The piping which extends from the backwash outlet of the filters to its terminus at the point of disposal.
- 12. Receptor**—An approved fixture or device of such material, shape and capacity as to adequately receive the discharge from indirect waste piping, so constructed and located as to be readily cleaned.
- 13. Filter**—Any material or apparatus by which water is clarified.
- 14. Underdrain**—An appurtenance at the bottom of the filter to assure equal distribution of water through the filter media.
- 15. Filter Element**—that part of a filter device which retains the filter media.
- 16. Recirculating Skimmer**—A device connected with the pump suction used to skim the pool over a self-adjusting weir and return the water to the pool through the filter.
- 17. Overflow Gutter**—A trough in the wall of the pool which may be used for overflow and to skim the pool surface.
- 18. Filter Media**—The fine material which entraps the suspended particles.
- 19. Filter Sand**—A type of filter media.
- 20. Filter Rock**—Graded rock and gravel used to support filter sand.
- 21. Pool Depths**—The distance between the floor of the pool and the maximum operating level when pool is in use.
- 22. Pool Decks**—The paved area around the pool.
- 23. Width and Length**—Shall be determined by actual water dimensions.
- 24. Lifeline Anchors**—Rings in wall of pool at transition point between shallow and deep area.

CONSTRUCTION

The design and construction, as well as all equipment and materials, shall comply with the following requirements:

- 1. Structural Design**—The pool structure shall be engineered and designed to withstand the expected forces to which it will be subjected.
- 2. Wall Slopes**—To a depth of 5 ft from the top, the wall slope shall not be more than 1 ft horizontal in 5 ft vertical.
- 3. Floor Slopes**—The slope of the floor in the shallow end shall not exceed 1 ft vertical to 7 ft horizontal. The transition point between shallow and deep water shall not be less than 4½ or more than 5 ft deep.
- 4. Lifeline Anchors**—Provide recessed lifeline anchor in wall of pool at transition point between shallow and deep area.
- 5. Diving Area**—Minimum depths and distances shall be as shown in table below.

DIVING AREA—MINIMUM DEPTHS AND DISTANCES

Diving Boards	Maximum Distance Above Water, in.	Minimum Depth, ft	Distance from Diving Wall, ft	Distance from Deep Point to Transition Point, ft	Minimum Overhang, ft	Minimum Width to Center of Board, ft
Deck Level	18	8	10	10	2½	7
Residential	30	8	11	11	2½	7½
1 meter	39.37	8½	12	12	3	8

SWIMMING POOLS

Residential Swimming Pools

MECHANICAL

1. Filters—Every pool shall be equipped with a recirculating system capable of filtering the entire contents of the pool in 18 hr*, or less, when the flow is calculated at a maximum of 5 gallons per minute, per square foot of filter area.

a. Filters shall be capable of maintaining the clarity of the water to permit the ready identification, through an 8 ft depth of water, of a disc 2 in. in diameter, which is divided into four quadrants in alternate colors of red and white.

b. Filter capacity shall be such that it need not be cleaned more frequently than once every four days under normal operation.

c. All filters shall be equipped with influent and effluent pressure gauges, to determine the pressure differential and frequency of cleaning.

d. All filter systems shall be equipped with an air release at the high point in the system. Each filter shall be provided with a visual means of determining when the filter has been restored to original cleanliness.

e. Operating instructions shall be posted on every filter system and all valves shall be properly designated with metal tags, indicating purpose.

2. Sand Pressure Filters—Sand filter systems shall be designed and installed to operate at a rate not to exceed 5 gallons per minute, per sq ft of filter area and to backwash at a minimum rate of 10 gallons per minute, per sq ft of surface area.

a. Filter tanks shall be fabricated to 1956 ASME Specifications for noncode pressure vessels, with the exception that standard type dished and flanged heads may be used. Tanks shall be built for a minimum of 50 pounds working pressure and tested at 150 psi. The filter underdrain shall have an effective distribution of at least 25 per cent of the cross-sectional area of the tank. Tanks placed underground shall be steel plate at least $\frac{3}{16}$ in. in thickness, with an approved non-corrosive exterior coating.

b. Filter tanks shall be supported in a manner to prevent tipping or settling.

3. Filter Media Specifications*

a. Filter sand shall be a hard uniformly graded, silica material with effective particle sizes, between 0.45 and 0.55 millimeters in diameter, with uniformity coefficient of 1.45 to 1.69. There shall be no limestone or clay present.

b. Filter sand shall be no less than 19 in.

in depth with a freeboard of no less than 9 in. or more than 12 in.

c. There shall be no less than four grades of rock, which shall be clean, non-crushed, rounded, non-calcareous material.

d. The total depth of the rock supporting bed shall be no less than 15 in. and each grade shall be 2 in. or greater in depth. Each layer of rock shall be leveled to prevent intermixing of adjacent grades.

e. The top layer shall vary in size between $\frac{1}{8}$ and $\frac{1}{4}$ in. The next layer shall vary in size between $\frac{1}{4}$ and $\frac{1}{2}$ in. The next layer shall vary in size between $\frac{1}{2}$ and $\frac{3}{4}$ in. The bottom layer shall vary in size between 1 and $1\frac{1}{2}$ in.

4. Recirculating Pumps—The recirculating pump shall have sufficient capacity to provide the rated flows of the filter system, without exceeding the head loss at which the pump will deliver such flows. The pump motor shall not be operated at an overload which exceeds the service factor.

a. Pool pump shall be equipped on the inlet side with an approved type hair and lint strainer. The basket of the strainer shall be non-corrosive and have an open screen surface of at least four times the cross sectional area of the inlet pipe.

5. Pool Piping—Shall be sized to permit the rated flows for filtering and cleaning without exceeding the maximum head, at which the pump will provide such flows. In general, the water velocity in the pool piping should not exceed 10 ft per second. Where velocity exceeds 10 ft per second, summary calculations should be provided to show that rated flows are possible with the pump and piping provided. The recirculating piping and fittings shall meet the following requirements:

a. The vacuum fitting(s) shall be in an accessible position(s) below water line.

b. A main outlet shall be placed at the deepest point in every pool for recirculating and emptying the pool.

c. Pool recirculation piping, passing through the pool structure, shall be copper tubing (with a minimum wall thickness of Type "L") brass or an approved equal.

d. Filtered water inlets shall be provided in sufficient quantity and shall be properly spaced to provide a maximum circulation of the main body and surface of water.

6. Valves—Fullway valves shall be installed throughout, to insure proper functioning of the filtration and piping system.

a. A valve shall be installed on the main suction line located in an accessible place outside the walls of the pool.

b. Valves up to, and including 2 in. in size

shall be brass. Sizes over 2 in. may have cast-iron or brass bodies. All working parts of valves shall be non-corrosive material.

c. Combination valves may be installed if the materials and design comply with the intent of these standards.

7. Tests—All pool piping shall be in compliance with these standards and the installation and construction of the pool piping system in accordance with the approved plans. The entire pool piping system shall be tested with a water test of 50 psi and proved tight before covering or concealing.

WATER SUPPLY AND TREATMENT

The potable water supply to any swimming pool shall be installed as required in AWWA Standards.

a. Unless an approved type of filling system is installed, such as is required by AWWA, any source of water which may be used to fill the pool shall be equipped with backflow protection.

b. No over the rim fill spout will be accepted unless located under a diving board or installed in a manner approved by local authorities so as to remove any hazard.

GENERAL

Wherever building regulations are established, generally the requirements are similar to those listed below.

a. Before commencing the installation of any swimming pool, a permit authorizing such work shall be obtained from the building department.

b. Application for permits shall be accompanied by plans and calculations in duplicate or triplicate and in sufficient detail showing the following:

1. Plot plan, elevations with dimensions all drawn to scale.

2. Pool dimensions, depths and volume in gallons.

3. Type and size of filter systems, filtration and backwash capacities.

4. Pool piping layout, with all pipe sizes and valves shown, and types of materials to be used.

5. The rated capacity and head at filtration and backwash flows of the pool pump in gpm with the size and type of motor.

6. Location and type of waste disposal system.

7. Structural, calculations and details prepared and signed by a registered engineer.

c. Set Back—Swimming pools shall be classified as accessory structures and conform to setbacks as required for such structures in local building codes.

*Note: Standards for diatomaceous earth filters are presently being prepared by a National Committee of diatomaceous earth filter manufacturers.

Recreation and Entertainment

SWIMMING POOLS

Residential Swimming Pools

MINIMUM FILTER AND PIPE SIZES

FOR RESIDENTIAL POOLS WITH CONVENTIONAL SAND PRESSURE FILTERS Based on: Maximum filter rate—5 gpm per sq ft of filter area. Minimum backwash rate—10 gpm per sq ft of filter area. Complete turnover of pool capacity in 18 hours.

POOL CAPACITY		FILTER SIZE		FILTER AND BACKWASH RATES	
Maximum Pool Capacity		Filter Diameter	Filter Area	Filter Rate	Backwash Rate
9,550 gal		18 in	1.77 ft	9 gpm	18 gpm
11,750 gal		20 in	2.18 ft	11 gpm	22 gpm
17,000 gal		24 in	3.14 ft	16 gpm	32 gpm
26,400 gal		30 in	4.90 ft	25 gpm	50 gpm
38,200 gal		36 in	7.07 ft	35 gpm	71 gpm
51,900 gal		42 in	9.62 ft	48 gpm	96 gpm
67,800 gal		48 in	12.57 ft	63 gpm	126 gpm

PIPE VELOCITIES IN FEET PER SECOND (Based on Standard Steel Pipe)

Flow Rate	Pipe Size		Flow Rate	Pipe Size			
	¾ in	1 in		1¼ in	1½ in	2 in	2½ in
9 gpm	5.4		32 gpm	6.6			
10 gpm	6.0		35 gpm	7.5

LOCKER ROOMS

2

DESIGN NOTES

Dressing-Locker Room. An average of 14 sq. ft. per pupil in the designed peak load should be provided exclusive of the locker space so there will be adequate dressing area. Check list: sufficient mirrors, built-in drinking fountain and cuspidor in boys' dressing room, tack board.

Storage Lockers. Each pupil enrolled should have a storage locker, with an additional 10 per cent to allow for expansion. Recommended sizes, in order of preference are: $7\frac{1}{2}$ by 12 by 24 in., 6 by 12 by 36 in., $7\frac{1}{2}$ by 12 by 8 in. These were selected as being the minimum size lockers to store ordinary gym costumes and allow free hanging for ventilation.

Dressing Lockers. Lockers large enough to accommodate street clothes should be provided. The number should equal the peak load plus 10

per cent. Lockers 12 by 12 by 72 in. are recommended for secondary schools and 12 by 12 by 54 in. or 12 by 12 by 48 in. for elementary schools.

Shower Room. In the group or gang type shower, the girls should have a number of shower heads equal to

1

These plans show three dressing-locker room arrangements, each with its own particular advantages. Dressing lockers are marked with X's. Plan 1: storage lockers are grouped in small space for economy in drying uniforms with forced warm air; some congestion may result from dressing lockers being next to one another. Plan 2: distributing dressing lockers over entire area gives each participant ample dressing space. Plan 3: dressing lockers distributed over entire suite; units can be installed in any number desired and lend themselves to group dressing method for girls. By constructing walls A, B, C and D, putting a grille to ceiling above locker tiers and installing grille sliding doors at E, each unit becomes a complete dressing room for community use. Walls A, B, C and D can be omitted and gates F added to get same use and permit towel service and toilet units to be installed at points A and D

3

40 per cent of the designed peak load; for boys 30 per cent.

Shower heads should be at least 4 ft. apart, of a non-clogging type; height of spray should be adjustable by use of a lock. If stationary heads are installed, they should be placed

LOCKER ROOMS

so that the top of the spray will be shoulder height (usually $4\frac{1}{2}$ to 5 ft.).

One to three individual shower booths, 3 by $3\frac{1}{2}$ ft., should be provided additionally for girls.

For boys, if walk-way or walk-around shower system is desired, the number of shower heads in the shower room can be reduced by one-third. In the walk-way, spray outlets attached to the water pipe must be focused to provide coverage from shoulder height to feet. There must be a continuous spray the length of the walk-way arranged so that there will be warm, tepid and cool water as one progresses along the walk-way. The walk-way should be arranged in U shape with a total length at least 35 ft. and from 3 to 4 ft. in width. An entrance from the group shower soaping space and egress to the towel-ing room and swimming pool should be provided.

Both individual and master control should be provided for all groups or gang showers. The booth showers should have individual control; the walk-way only master control.

Towelng Room. The towelng room should have the same total area as the shower room and be immediately accessible to both showers and dressing room.

Suggested locker and bench installation

When locker height is kept down to 54 in., entire room can be supervised. Sloping locker top cannot be used, but 4 in. ventilating space should be louvered.

A ledge 18 in. high and 8 in. wide coved at wall and base, with bull nose edge, as foot drying aid is desirable.

If towel distribution is such that hanging of towels in drying room is necessary, a 1-in., non-corrosive towel bar 4 ft. from the floor and 1 to $1\frac{1}{2}$ in. from the wall is recommended.

A non-shatterable, transparent panel for supervision of towelng between the towelng and dressing room may be desired.

Towel Service and Storage Room. Adjustable shelves in sufficient number to accommodate the load are

required. A check-out window should open into or be immediately adjacent to the towelng room. If uniforms are distributed from here, a dutch door or check-out window, with counter, should open into the dressing room.

Toilet Room. Facilities should be provided in proportion to the peak load on the following basis:

Toilets	Girls	1-30	Min. 3
Toilets	Boys	1-50	Min. 2
Urinals	Boys	1-25	Min. 2
Lavatories	Girls and Boys	1-20	Min. 3

Typical combined storage-dressing locker arrangements

Area of the dressing-locker room suite required for different types of storage and dressing lockers in a typical unit for 240 girls or boys. Proportionate adjustments to be made for varying school enrollments.

Class Periods Per Day	Size of lockers and Battery Arrangement	Typical Installation	Overall height with base	Number students per day	Peak load per period	Area Required, sq. ft.	Recommendation *
six	6—storage $7\frac{1}{2} \times 12 \times 24''$ 1—dressing $12 \times 12 \times 48''$ or 6—storage $7\frac{1}{2} \times 12 \times 24''$ 1—dressing $12 \times 12 \times 72''$		54'' or 80''	240	40	114.80 or 90.0	1 a. grades 1-12 b. grades 9-12
six	6—storage $6 \times 12 \times 36''$ 1—dressing $12 \times 12 \times 72''$		80''	240	40	100.0	3 grades 10-12 only
six	6—storage $7\frac{1}{2} \times 12 \times 18''$ 1—dressing $12 \times 12 \times 54''$		62''	240	40	90.0	2 grades 1-12
eight	8—storage $7\frac{1}{2} \times 12 \times 18''$ 1—dressing $12 \times 12 \times 72''$		80''	240	30	67.50	2 grades 9-12
eight	8—storage $7\frac{1}{2} \times 12 \times 24''$ 1—dressing $12 \times 12 \times 48''$		54''	240	30	105.0	1 grades 1-12

* Numbered in order of Preference

BATHHOUSES

BATHHOUSES

Information in this section was prepared by Ronald Allwork from data assembled by the Portland Cement Association; Joint Committee on Bathing Places, American Public Health Ass'n.; Conference of State Sanitary Engineers.

General. Capacity and operation of the bathhouse must be such as to avoid overcrowding at times of maximum demand; however, it is better to have an overcrowded condition a few times a year rather than to have facilities so large as to be uneconomical.

Location of bathhouse depends partly on size of pool and space available. When possible, bathhouse should be placed so as to protect pool from prevailing winds. A location at one side of the pool, or better still, at the shallow end, will reduce the danger of poor swimmers and children falling or jumping into deep water.

Size of bathhouse and selection of equipment, in relation to pool size depend on such factors as the need for: lockers, or central checking system; individual dressing rooms, or the "dormitory" system; private or group showers; and extra facilities. If patrons are permitted to use their own suits, some will come ready to swim, and dressing and check rooms may be small. But since all bathers should be required to take a cleansing shower, the number of showers needed will remain the same.

Area of bathhouse is usually 1/3 of pool area; area of dressing room approximates 1/5 pool area. It is recommended that bathhouse facilities, based on the number of bathers present at any one time (2/3 of whom may be assumed to be men), be provided as follows:

- 1 shower for each 40 bathers
- 1 lavatory for each 60 bathers
- 1 toilet for each 40 women
- 1 toilet for each 60 men
- 1 urinal for each 60 men

For rough estimate of maximum number of persons within a pool enclosure (pool and walks) assume one person for every 12 sq. ft. of pool area. Hence for a pool 30 x 75 ft., assume 190 persons.

Elements of a bathhouse vary with local requirements, but usually include: entrance lobby, ticket or cashier's booth, concessions, manager's office, public telephones, checking room, suit and towel room, dressing rooms, toilets, showers, first aid room, guard's or attendant's room, mechanical equipment, storage space, etc.

Dressing rooms. Method of checking clothes must be decided before the layout can be determined, as the method chosen affects the entire arrangement. Both individual lockers and central check rooms have been used successfully. Choice depends mainly on local conditions. A combination of the two systems may become the most desirable, since obviously requirements for a well-dressed adult and for a boy in play clothes are not the same. Lockers should be placed on a raised platform to keep them dry and to simplify floor cleaning. Lockers require most space, but tend to keep clothes in better condition. Individual dressing rooms must usually be provided for women and girls, whereas men and boys ordinarily dress in aisles between rows of lockers. A few individual dressing rooms are sometimes provided in men's dressing rooms.

Regardless of the system adopted, dressing and locker rooms should be arranged to admit a maximum of sunlight and air in order to maintain clean, sanitary conditions. Satisfactory results have been obtained from the "open-court" type, in which the roof is omitted over part of the dressing room area.

Toilets of the wall-hung type are recommended.

Showers may be either individual or group-controlled; some type of control, which eliminates any possibility of bathers being scalded, is essential.

There are many types of bathhouse equipment on the market which add to the convenience of the patrons and increase the popularity of the pool. Hair driers, comb-vending machines, exercisers and scales are frequently installed.

Planning of bathhouse elements should be such as to permit operation with minimum of personnel, particularly during slack periods.

Circulation. Arrange all facilities so patrons can pass through quickly, without confusion. The only route from dressing room to pool should be past toilets and shower rooms. Each bather should be required to take a thorough cleansing shower with soap before putting on bathing suit. By requiring each bather to pass through a group of showers before entering the pool a superficial bath will be obtained, but this must not be considered as replacing the required shower in the nude.

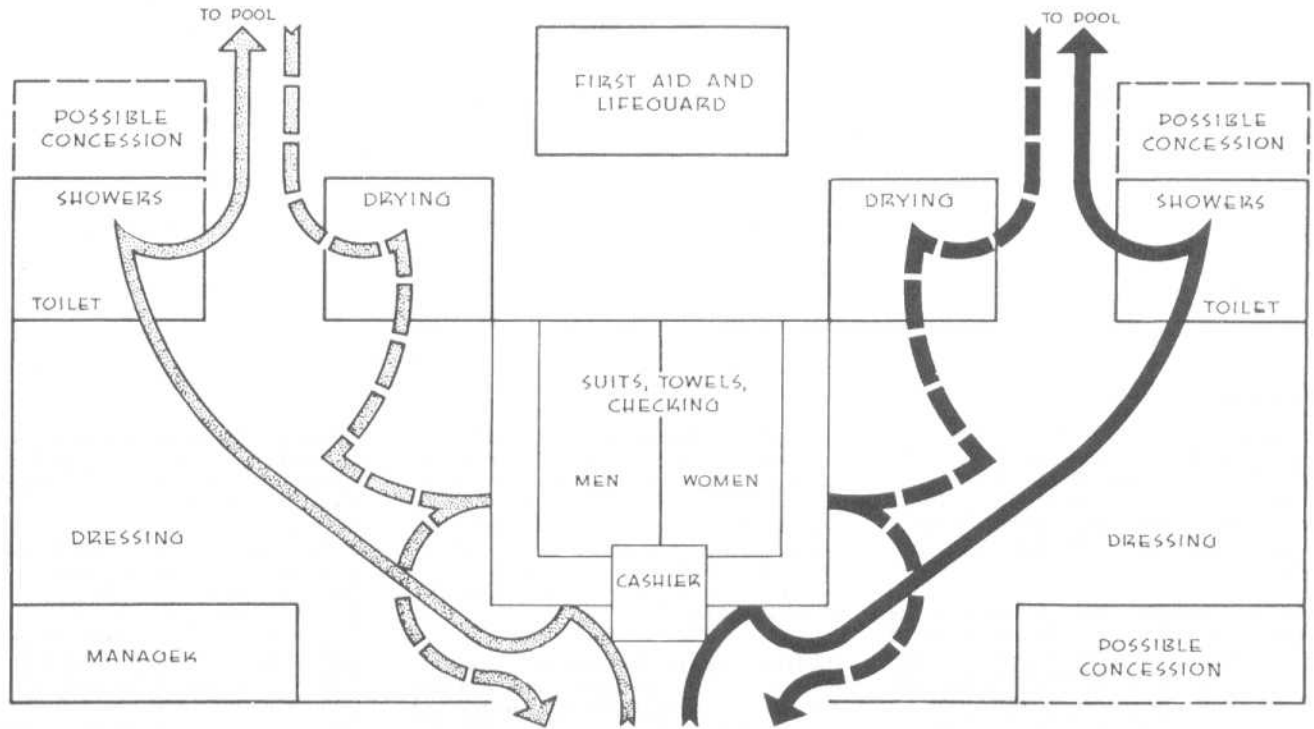

Toilets should be accessible directly from both dressing room and pool. Separate ones for "wet" and "dry" bathers are desirable. Disinfecting foot baths should be placed between pool and toilet.

Bathers returning from the pool should preferably pass through a separate drying room to the dressing room, and the "wet" and "dry" bathers should be separated as much as practical. Exit from bathhouse to street should be so arranged that an attendant may collect all keys, checks, suits or other supplies belonging to the establishment.

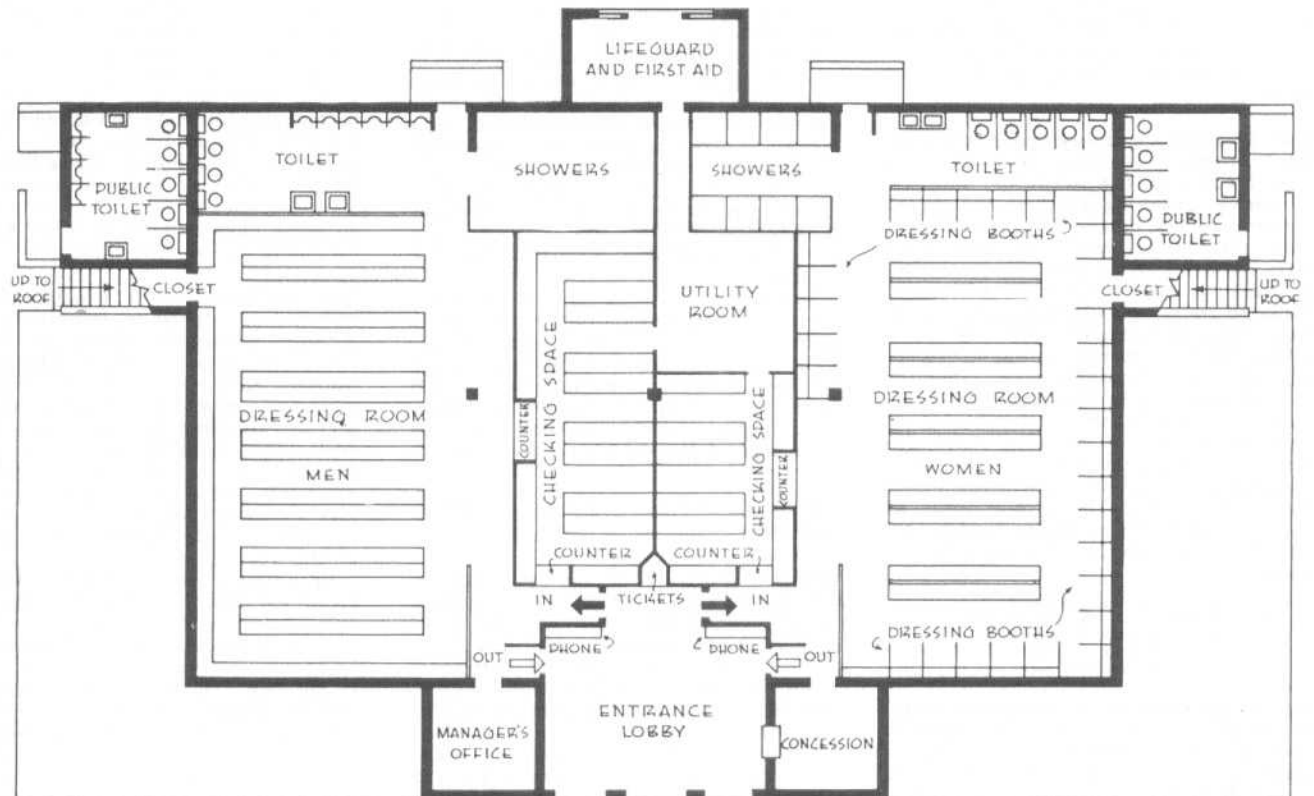

Construction. Resistance to deterioration and fire is especially important. The constant dampness which usually prevails is harmful to many materials and causes rapid deterioration. Therefore materials which are entirely satisfactory in ordinary buildings may not be desirable for bathhouses. Fire hazard must also be considered in selection of materials, particularly since the building is generally in an isolated location and without attendants a good portion of the year.

Bathhouses must be kept scrupulously clean by frequent washing. Construction should be such that washing with high pressure hose will not damage the building. Floors of bathhouses should be pitched 1/4" per ft. to frequent outlets to assure rapid drainage. Provide an ample number of hose connections to make cleaning easy. Connection should be not less than 1 in. to insure adequate water volume and pressure.

ZOO PLANNING

A. Display Arrangements or Themes

Introduction The categories described below are representative more of planning concepts than of existing facilities. Classification of any given zoo depends largely on its history, i.e., whether it was developed from the very beginning along a definite theme or whether it "grew like Topsy," with buildings and exhibits constructed as immediate circumstances and interests dictated. By far, the vast majority of zoos are in the latter category with very few institutions "master planned" from their inception and then built along orderly planned lines and stages of growth. It is hoped that master planning in zoos will increase.

The general present day lack of master-planned zoos is due largely to an absence of adequate financial support at the zoo's inception. In general, most zoos attain a stage somewhat after their inception where future developmental potential is assured. It is at just such a stage that a comprehensive and overall plan for future growth and development is frequently prepared, namely a "master plan." As a result of such a history, most zoos today are in a transitional period wherein remaining elements of the "Topsy" period coexist with new stages of master-planned growth. Since a zoo is never really "finished," the typical zoo that has attained a stage of planning maturity is actually in some phase or other of its master plan development. The older a zoo, the more periods of reevaluation and master planning it generally passes through, since new ideas and new techniques of animal display are constantly being developed, altered and then discarded in response to new philosophies of zoo functions. Certainly, wherever possible and practical, a city contemplating either a new zoo or a vast remodeling of an old one should give top priority to the preparation of a master plan.

A zoo may be classified as one of the following display types according to the nature and arrangement of its exhibits; systematic, zoogeographic, habitat, behavioral, "popular," or, most frequently, some combination of these. (See Fig. 1.)

1. Systematic Themes The arrangement of exhibits according to their taxonomic or systematic relationships; thus, all cats in one exhibit area, bears in another, hoofed animals together, etc. Historically, the earliest zoos ("menageries") were developed along this theme. From a practical standpoint of design and construction, the systematic theme allows a certain ease of daily maintenance and husbandry.

One of the distinct advantages of a systematic arrangement is the opportunity to empha-

size differences and similarities of related species within a single animal group. Such advantages are gained through the adjacent exhibition of related species permitting comparative viewing.

An entire zoo planned along systematic lines has been criticized as a source of "exhibit monotony." That is, when the visitor is confronted with several species in the same animal group (e.g., monkeys, bears, cats, etc.) the relative similarity in these animals tends to inhibit exhibit interest. Also, in such a display a species, which may be an outstanding exhibit by itself, may lose its attractiveness or effect when shown alongside other perhaps more spectacular members of its family group. In short, when the average visitor is confronted within a limited area with several similar animal species, he tends to be attracted to the more spectacular species often to the detriment of the others; also visitor interest declines as the number of similar animals increases until, when his saturation point is reached, he may leave an otherwise outstanding exhibit of animals for something simply "different." By breaking up such systematic exhibits (as in a zoogeographic theme) visitor interest is maintained at an optimum level with maximum exhibit diversification of similar species.

2. Zoogeographic Themes The arrangement of animal exhibits according to their geographic origin, e.g., New World, Old World, European, Asian, Eurasian, African, Australian, Australasian, Tropical American, Temperate American, Polar, Texas, etc. Thus, all of the animals in an entire zoo may be arranged zoogeographically or continentally. With such arrangements, there is practically no limit to the extent of imaginative exhibit supplements such as the use of native props from the same area as the animals, background music geographically keyed, architectural style, planting, and other exhibit features also geographically oriented. Such themes need not be worldwide in scope, but can be restricted to a given geographic area. Thus, "animals of the Southwest," "animals of Idaho," "animals of the Rocky Mountains," etc., with the concepts limited only by the imagination of the planner and available resources.

Regional zoogeographic themes would seem ideal for smaller zoos as they permit an institution with limited finances to do a small job well rather than do a big job poorly. Regional pride and expression also are important and advantageous factors in support of a regional theme.

From a practical standpoint, utilization of a local regional theme offers several inducements; ready availability of most animal species; few or no acclimational problems; generally less expensive and less complicated demands for physical structures, maintenance and operation when compared to the needs of exotic animals; and a ready availability of acclimated plants and natural exhibit props for naturalistic landscaping.

With so many apparent advantages it is diffi-

cult to understand why so few regionally oriented zoogeographic theme zoos have been built.

3. Habitat or Ecological Themes The exhibit presentation of animals selected from a given habitat has been practiced for years in public aquariums where animals (and plants) of an aquatic habitat are displayed in a single building. Thus, although an aquarium with a comprehensive exhibit may show a predominance of fishes, other representatives of the animal kingdom may also be displayed, e.g., invertebrates (sea anemones, starfish, crabs, crawfish), amphibians (frogs, toads, salamanders), aquatic reptiles (turtles, crocodilians, snakes), aquatic birds (penguins) and aquatic mammals (seals, sea lions, manatees, porpoises, walruses, and even whales). Surprisingly, although aquariums are generally associated with fish displays, the non-fish exhibits such as octopuses, seals, porpoises, large turtles, often are the most popular with the public.

The development of other habitats as theme exhibits has met with excellent public acceptance. Such habitats as "grasslands" (the popular African veldt displays, Pampas scenes, North American prairie exhibits, etc.), rain forests, subterranean exhibits (animals in burrows and cave settings), desert exhibits, etc. are forerunners of a potentially very popular and educational exhibit theme trend. In such ecologic displays naturally associated plants and animals of diverse groups (mammals, birds, reptiles, etc.) may be shown living together (or, more correctly, *apparently* together—often separated from one another by hidden barriers). Frequently, predator-prey relationships can be implied.

The educational and popularity potential of a habitat display is extremely high. It emphasizes the higher relative value of a single, large and well-executed exhibit of dozens of species and individuals as compared to a series of several dozen smaller cages each showing a single species. Depending on design, the single habitat display may involve less maintenance costs than the series of single cage units. Thus, for relatively small zoos or limited operations, adoption of a habitat theme permits maximum display for minimum budget expenditure. Due to inherent problems in such community type exhibits (competition and predation among species, plant-eaters, etc.), a small zoo should restrict itself to those designed, built and operated with a minimum of complications.

4. Behavioral Themes This relatively unexploited display area offers considerable exhibit potential. More time, research and development will undoubtedly be required before many of these display techniques are within the operational scope of the average zoo.

Typical of a behavioral exhibit theme is a nocturnal animal display where animals normally active only at night, are exhibited in darkened buildings. Special lighting is used which causes them to "reverse" their normal activity cycle, thus rendering them observable

Zoological Park Fundamentals, American Association of Zoological Parks and Aquariums, a professional branch of the National Recreation and Park Association, Washington, D.C., 1968.

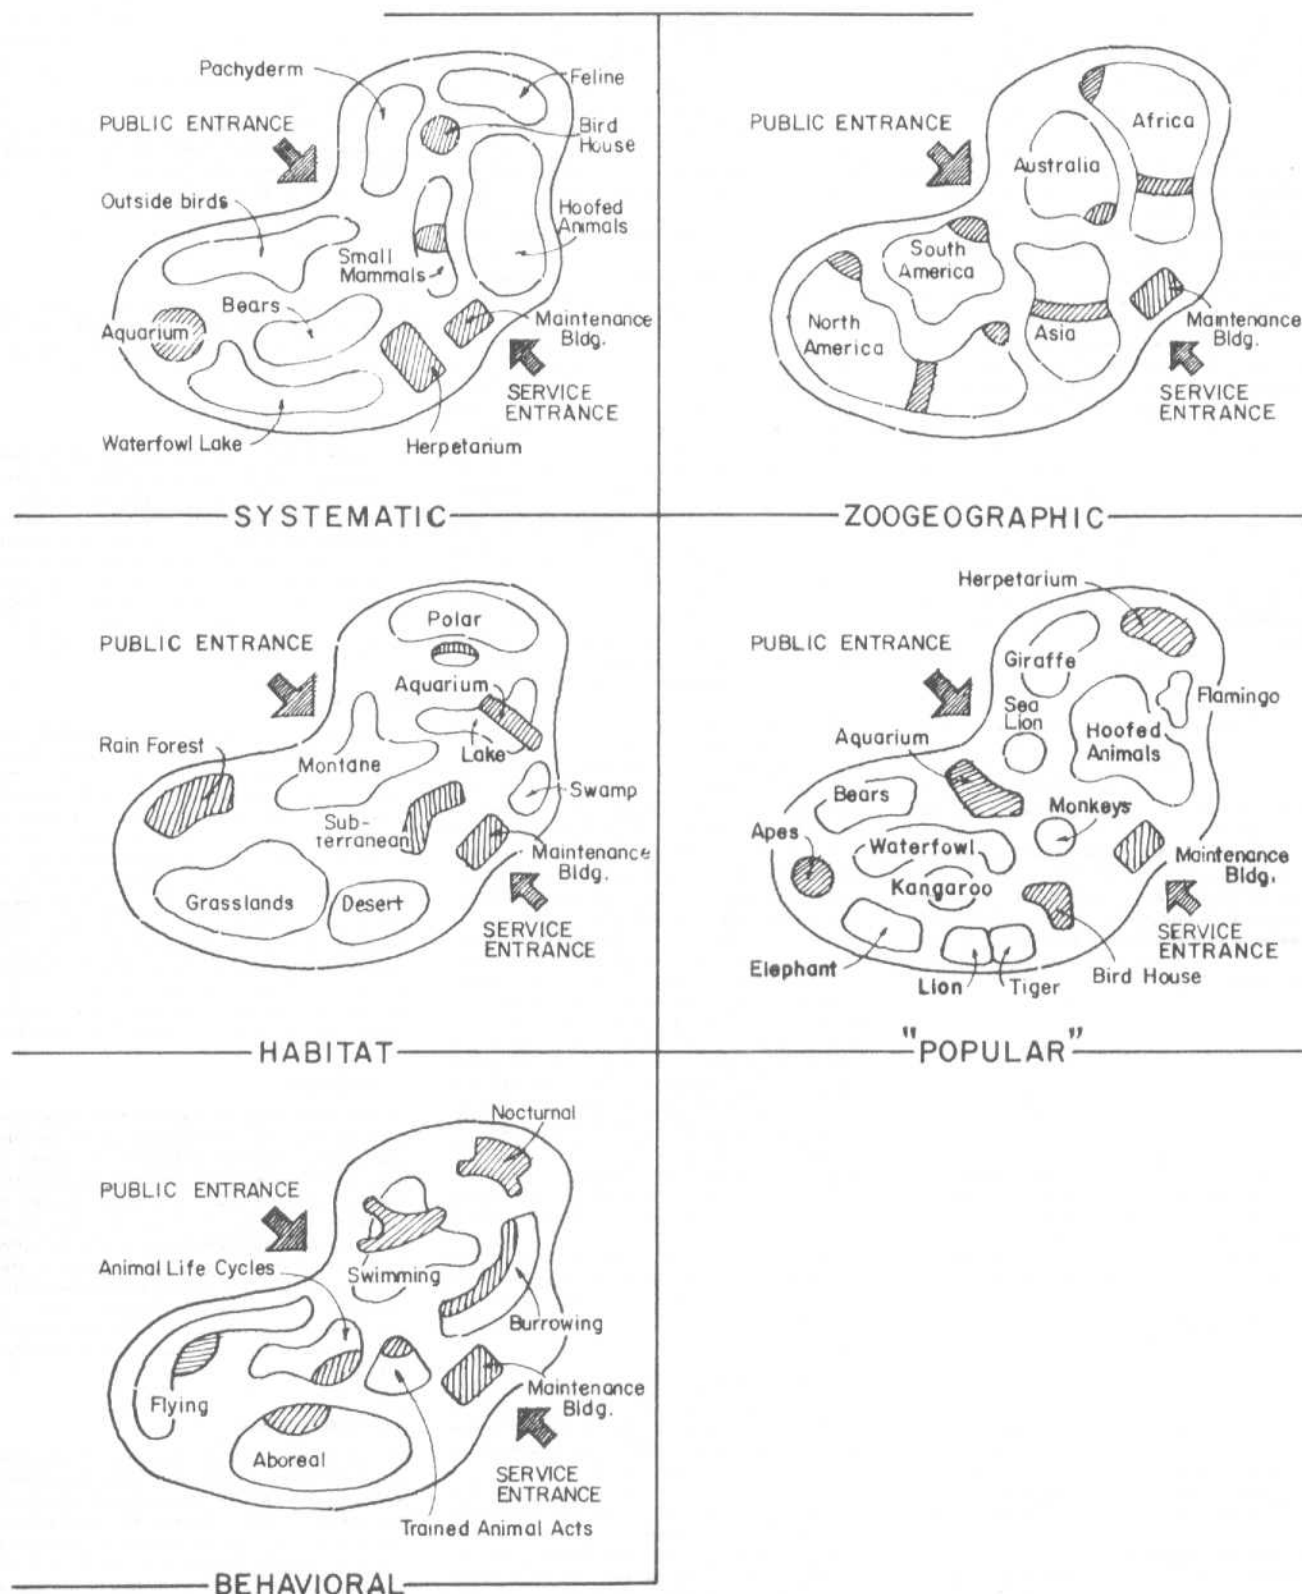

Fig. 1 Five basic display arrangements. Hatched areas indicate buildings. An entire zoo designed strictly along one display theme presents several practical problems of animal exhibit husbandry. Hence the display concept of a zoo's master plan usually involves a careful selection and combination of several themes.

by the visiting public in the daytime. In this way animals which are otherwise seen curled up asleep in the conventional "daytime" zoo exhibit are changed into active and fascinating creatures in the nocturnal display. Another example of a behavioral theme are the relatively new "automatic" trained animal acts wherein the conditioned reflex is utilized as a means of extracting certain behavior from an animal. To date these acts have been more or less limited in their application to domestic animals and a few wild species. Application of this technique to zoo exhibits holds tremendous potential for the future. Thus, in effect, zoos may exhibit not just an animal but, at the push of a button or drop of a coin, an animal going through a given sequence illustrating natural or instinctive behavior. Examples might be a raccoon removing bird eggs from a nest or a cheetah pursuing an artificial antelope.

In addition to the above, other behavioral themes which could be considered are "flying animals," "swimming animals," "burrowing animals," "climbing animals," etc. Even a comprehensive exhibit of the love life of animals—courtship, nest building, egg laying, incubation, birth, and care of offspring—has exhibit potential and stirs the imagination, perhaps in more ways than one. Depending on interpretation, the dividing line between habitat and behavioral themes may become indistinguishable.

5. "Popular" Theme Some zoos, particularly relatively small facilities, may wish simply to exhibit a limited number of animals selected and presented strictly on the basis of popular appeal rather than zoological orientation; thus the display theme would have no particular basis as regards geographic origin, systematic relationship, or such. On the basis of visitor interest, the following list might be considered a reasonably complete selection of the more popular animals generally available to zoos:

Mammals:

Giraffes	Bears
Camels	Apes
Zebras	Monkeys
Elephants	Otters
Lions	Sea lions
Tigers	Kangaroos

Birds:

Colorful, exotic, perching species	Hummingbirds
Toucans	Waterfowl (ducks, swans, and geese)
Eagles (and other birds of prey)	Parrotlike birds
Flamingos	Pheasants
Penguins	
"Giant" birds (rhea, cassowary, ostrich, emu)	

Reptiles:

Large boas and pythons	Giant tortoises
Venomous snakes	Native snakes
Large lizards (monitors)	Colorful reptiles
	Alligators and crocodiles

Exhibits and others:

Aquariums	Contact areas for children
Herpetariums (reptile and amphibian exhibits)	Trained sea lion shows
"Open-fronted," "walk-through," or free-flight bird displays (indoor or outdoor)	Monkey islands

Taken as a whole, selections from the above "building-block animals" would form an excellent basic collection for any small zoo. In such a plan each exhibit should be carefully selected and designed so as to achieve maximum visitor appreciation and education. Imaginativeness of display and presentation can spell the difference between a poor exhibit and an outstanding one. Compare, for example, a "caged" lion inmate in a cellblock-type enclosure to a king-of-beasts in a planted veldt and viewed across a hidden moat. Both are lions but any exhibit similarity ends there.

Also, under the heading of "popular" type themes might be included exhibits of animals that are oriented to a particular group, such as children. These exhibits are called by such names as "Children's Zoo," "Petting Zoo," "Story Book Zoo," "Mother Goose Zoo," "Junior Zoo," etc. Often nursery rhymes or children's story themes are used as the basis of such exhibits. Perhaps their main value is the presentation of an opportunity, especially to children, to hold, feed, or merely to touch an animal in safety. Thus, in these exhibits children are able to establish an especially close relationship with a live animal, a situation usually impossible in the conventional zoo. Certainly, many child-oriented zoos attract adults as well as children, and their design is frequently an adult inspiration of what children should be attracted to.

6. Combination Theme Obviously, unless master planned from the very beginning and along a single exhibit theme, most zoos are arranged in combinations of the above categories. Due to practical maintenance factors (animal factors as well as mechanical and architectural considerations) it is often more feasible to develop exhibits along a basic systematic theme; however, it is possible to combine display themes, thus gaining the multiple advantages and increasing the educational value of the displays.

For example, in a single building, a bird house (systematic theme), the individual exhibits might be grouped according to country or area of origin (zoogeographic theme). Included among the exhibits might be a rain forest or "jungle" scene consisting of birds, selected other animals and plants (habitat theme). A demonstration display of eggs incubating and hatching (a biological theme?) and a pushbutton activated trained bird demonstration of the pecking and scratching instinct (behavioral theme). Thus illustrated in a single building would be several different exhibit themes.

Utilization of various theme combinations has the further advantage of presenting the visitor with a variety of interest appeals and further reducing the possibility of exhibit monotony.

7. Zoo-Botanic Garden Combinations A most natural, logical, and financially sound arrangement is the combining of zoological and botanical gardens into a single entity. The advantages of such a combination are as follows:

a. Since zoos require landscaping, the combination operation enables the botanical aspect to serve a dual purpose.

b. In habitat and zoogeographic theme exhibits, the use of landscape materials appropriate to the animal's place of origin adds further to the educational and esthetic value of the display.

c. In nature, animals and plants are not separated systems but closely interrelated and interdependent upon one another. Such is the basis for the science of ecology. Separation of the two groups exhibitionally is thus an unnatural and generally unfortunate division.

d. Both zoological and botanical gardens have essentially the same basic purposes as reasons for their existence. Hence separate operations involve overlap of functions and subsequent fiscal overlap.

Possible disadvantages of combined zoological botanical exhibits might exist where separate facilities are desired so as to reduce visitor concentration in a single area.

GROUNDINGS

Specific features of the grounds, features which are not considered as part of the animal exhibits or maintenance structures, are discussed here.

A. Parking Areas

Adequate parking facilities should be planned to accommodate the average periods of maximum visitation. Various indices are available to planning engineers by which the estimated number of parking spaces needed to accommodate such periods can be determined. It is perhaps questionable to attempt to provide adequate space at a zoo to accommodate the two or three peak days of the year, which are generally the fourth of July and Labor Day.

B. Entrance

Generally, a combination entrance and exit for the public is most practical and preferable. Obviously, the fewer entrances and exits, the better the grounds security and visitor control. A single entrance-exit centrally located is optimum. Turnstiles with counters afford actual attendance checks which are always of interest in measuring the popularity of the zoo, evaluating peak loads, etc. Dogproof turnstiles are available and have special value since pet animals of any kind should be prohibited from zoos for reasons of animal health and safety. A separate entrance and exit for service vehicles should be available and as far removed from the visitor entrance as possible.

C. Landscaping

Proper horticultural treatment of the zoo grounds adds tremendously to the naturalistic and esthetic setting. Selection of plants of course is generally a function of local conditions of soil, climate, topography, as well as available irrigation facilities. As discussed above, continental plantings can be imaginatively incorporated into continentally oriented exhibits plans. Floral displays add color to the grounds and especially fragrant plantings provide a pleasant atmosphere. If plant species are labeled, then the zoo functions as a botanical exhibit as well.

D. Animal Sculpture

Zoos are ideal settings for sculpture gardens, especially animal sculpture. Many zoos locate specific pieces of animal art in association with live exhibits of the same animal. Correlation of the arts with zoo display is another example of the modern multipurpose zoo. Models and restorations of prehistoric animals also are appropriate for zoos, especially when integrated into exhibit areas of their living relatives.

E. Miscellaneous

Several items are considered here:

1. **Walks** Adequate sized walks of concrete, asphalt, or similar low-maintenance and per-

manent materials should be used. Nonskid walks should be provided wherever grades indicate. Zoo visitors frequently have their interest (and eyes) on exhibits rather than where they are walking and hence grounds planning should be especially safety oriented. Steps should be avoided wherever possible for the same reason. Low-incline ramps should be substituted wherever possible. Such planning also facilitates visitors with wheelchairs, baby carriages and especially baby strollers, the latter a frequent and useful vehicle of zoo visitors.

Use of nonstabilized materials for walkways should be avoided in zoos as any likely object can become a missile in the hands of a vandal.

The width of zoo walks is an important factor since they are used for both walking as well as standing and looking. Walks fronting exhibits of high popularity require extra room to avoid traffic jams. Adequate space for future walkway enlargement should also be provided.

Some zoos have postponed initial installation of permanent walks and planting until the grounds had been used for a period of time by heavy visitor traffic. In this way, the public in effect determined their own walking routes—a habit pedestrians are often prone to do anyway unless extensive barriers are installed.

2. Visitor Transportation Systems Provisions for a visitor transportation system should be included in the initial zoo plan. Many zoos which have omitted this provision in their early planning have suffered later from cramped transport facilities as a consequence. Systems using tractor buses, miniature or narrow gauge trains, monorails and cable cars have all been successful in zoos.

3. Barriers Depending on the danger involved, barriers of one type or another are necessary to maintain the visitor at a safe distance from the animals. Guard rails, chains, cables, low fences, masonry walls, hedges (often with wires concealed in them), spiny plantings, etc., all function in this respect. In general, the least conspicuous (yet effective) barriers are to be desired.

4. Benches Since considerable walking is usually necessary in zoo visiting, rest areas for visitors should be available throughout the grounds. At the more popular attractions many spectators enjoy an opportunity to view the exhibit while seated and proper planning takes this need into account. Bird exhibits are particularly well suited for such passive recreation. Benches are best located on paved areas to simplify litter.

5. Perimeter Fence In addition to a controlled entrance and exit, the installation of a complete perimeter fence permits added visitor control and grounds security. With a complete perimeter fence, the ingress of predatory animals (such as raccoons, cats, dogs) is limited. Likewise, escaped zoo animals are more or less confined within the grounds. The addition of barbed wire at the top and a concrete footing or curb at the base adds to the effectiveness of the perimeter fence.

ANIMAL EXHIBITS

A. Introduction

In general, there are three basic and sometimes conflicting needs to be considered in planning a zoo animal exhibit, namely those of the animal, the visitor, and the attendant.

The needs of the animal take precedence

over those of the other two. Since different animal species have different needs, it is important to select those species whose needs can be met without conflicting with those of the visitor and the attendant. Intelligent exhibit design, however, resolves many such conflicts and thus increases the variety of animals which may be exhibited in zoos. It therefore behooves the zoo architect to seek as much technical information and help as is available on the biological needs of the animals to be exhibited.

What has been termed the "social environment" of captive animals is as yet a poorly understood phenomenon but one which may very well exert strong influences on the health and longevity of animals in captivity. Enclosure design should reflect our knowledge of species' requirements, optimum group size, space needs, sex ratios, and facilities for exercise.

B. Design Factors to Be Considered

In order to properly design an animal exhibit which will satisfy the three basic needs cited above, the following factors should be considered:

1. Exhibit Size Largely determined by the size and activity of the animal. As a general rule, with many exceptions, however, the larger the quarters, the greater will be the husbandry success of the species.

2. Exhibit Shape Also determined largely by the specific kind of animal involved. In any case, acute corners are to be avoided since animals very often will panic when driven into a tight place.

3. Exhibit Orientation Where large areas are involved, the greatest dimension should parallel the public viewing area so as to keep the viewing distance between the visitor and the animal to a minimum. Orientation of the exhibit to the sun, especially during the summer season, should also be evaluated for special requirements or problems. Excessive glare in the viewers' eyes should be avoided, and the amount of sun which might be beneficial or detrimental to the particular animal involved should be considered. Excessive exposure to sun can be a serious health as well as maintenance problem. This is especially true of aquatic exhibits with their problems of algal control.

4. Materials Should be selected for ease of maintenance (nonporous, long wearability, low upkeep, permanence), naturalistic appearance, nontoxicity, readily available construction items in standard sizes, shapes, and specifications, etc. Due to constant exposure to weather, cleaning abrasives and detergents, acidic animal wastes, etc., the selection of exhibit construction materials used in a zoo require special investigation. Nontoxic paints should always be specified where animal contact is possible.

5. Eye Level Depending on the habitat preferences of the animal in nature (ground-living, tree-living, etc.) the visitor's eye level should be considered accordingly in planning the floor and ceiling elevations of the exhibit. In this way the animal will be within maximum viewing range of the visitor. In especially large exhibits, several visitor observation areas are often included—frequently at varied levels.

6. Step-ups Since zoo visitors occur in all sizes, from very young children on up, it behooves the designer to ensure adequate obser-

vation facilities for everyone. Where cage floors must be above floor level, the use of step-ups for children and short adults are helpful. Observation platforms of several "stepped-up" levels or ramped up decks are useful for highly popular exhibits where crowds cause visibility problems.

7. Props or Decorations Such items as are used to impart a natural setting for the exhibit in addition to fulfilling certain biological and psychological needs of the animal. Examples such as plants, trees, and rock work, termite nests (any one of which may be real or artificial), and even native artifacts (spears, shields, temple ruins, huts, etc.) all contribute to the display value of an animal exhibit. Strategically located cage props are important in providing hiding places for animals from one another, objects on which to rub, exercise, mark, sun, etc.

8. Shift Cages Enclosures should be designed so the animal may be easily shifted from the exhibit into an adjacent holding, isolation or reserve area without having to restrain or catch the animal. Viewing apertures should be designed into such facilities so that animal movements may be observed from a safe place by the attendant and, especially where flighty animals are involved, without the animal viewing the operator. Prisms used in such installations provide a wide angle of observation. The inclusion of a sliding wall of removable bars in a shift cage expands its function to that of a "squeeze cage"; another very useful item of animal husbandry. With the built-in squeeze cage an animal may be immobilized for veterinary treatment without the need of removing it from its exhibit area.

9. Barrier Depending on the kind of animal exhibited, many different types may be used to contain it within its enclosure. For esthetic reasons, those barriers which are the least visible are the most desirable. Barriers which have been used are of the following types (see Fig. 2):

- a. Vertical wires held under tension
- b. Bars
- c. Rails
- d. Moats (dry and water-filled)
- e. Fencing
- f. Walls (including such naturalistic features as vertical rock formations)
- g. Glass (both flat and curved or "invisible")
- h. Psychological (such as birds exhibited in a well-illuminated exhibit area and reluctant to fly into a darkened visitor area)
- i. Electrical ("shock" fences as well as charged glass windows)
- j. Thermal (refrigerated coils and hot water lines)

When structural barriers are used which interrupt the visibility of the exhibit, such restrictions may be reduced to a minimum by lowering the amount of light reflection from the barrier. With bars, fencing, etc., reflections can be reduced tremendously by painting the barrier flat black or other flat dark colors. Glass barriers, when improperly installed, become viewing barriers themselves when they pick up so many extraneous reflections that the exhibit is actually hidden from view. Tilted installations, the use of light-deflecting drop curtains and walls behind the viewer and the use of curved "invisible" glass all serve to reduce and eliminate reflections. Glass, of one design or another, is so widely used in zoos that its proper installation to avoid reflections is of paramount consideration. Glass may also serve as a viewing barrier when opaqued with condensed moisture. Frequently properly

Fig. 2 Barriers.

directed ventilation can correct this problem. So many zoos have suffered such unsatisfactory results that avoidance of these pitfalls cannot be overly stressed.

10. Security Adequate measures should be taken to prevent animal escapes, both by the animal breaking out through human error or because of vandalism. Exhibits in any way accessible to the public should always be key locked. Access doors and operating levers to dangerous animal enclosures should be clearly identified.

11. Illumination Adequate lighting must be available for satisfactory observation of the exhibit. Daylight has the advantages of being both natural and inexpensive. However, it is not always dependable, varies seasonally, and prevents interesting lighting effects obtainable only with controlled artificial lighting. Each exhibit has its own lighting requirements which must be resolved through investigation of the animal's needs and the effects desired. Installation of infra-red, ultraviolet and germicidal lights are often of special value with certain animal species. For indoor exhibits, the use of operational skylights has several advantages where direct unhindered sunlight and ventilation are of value to the health of the animal. As has been mentioned, shade is another important planning factor and is especially important where aquatic exhibits with their attendant algal growth are concerned.

C. "Grottos," "Pens," and "Islands"

1. The term "grotto" as applied to zoo exhibits usually has reference to designs in which the animal is separated from the visitor by a moat and prevented from escape elsewhere by sheer vertical walls (often leaning slightly inward). Pigmented concrete sprayed over irregular forms lends itself well to grotto

construction resulting in interesting and naturalistic artificial rock outcrops. Natural stone for such purposes is generally not conducive to realistic outcrops. However, carved natural stone has been used effectively in some instances. Properly designed grottos can be most effectively and beautifully landscaped. Adequately drained planter "pockets," if naturalistically located, will greatly "soften" otherwise drab rockwork.

Grottos may be used effectively for many kinds of animals—reptiles, mammals and flightless or pinioned birds. The value of the grotto is in the naturalness of the setting and the lack of a barrier to interrupt the visitor's view. Designers should give careful considerations to vertical elevations so as to avoid placing the animal in a "pitlike" atmosphere. Also, excessive use of rockwork may conflict with the animal's actual habitat; therefore, a study of the animal's natural history will prevent building an unnatural "natural habitat" setting.

In northern climates where outdoor exhibition may be impractical the year round, indoor exhibit cages often are included and connected directly to the outdoor exhibit.

2. The term *pen* generally implies a yard or area enclosed by fencing, quite large spatially and without top fencing. Animals which cannot climb or fly are adaptable for display in pens. Because of the large area involved, fast-running animals (especially hoofed stock) are usually kept in pens. The section of fencing along the visitor's side of a pen may be replaced with a moat barrier for a more effective display.

3. "Island" exhibits are essentially grottos which are surrounded by a moat. Generally, the same type of animals workable in grottos will do well on islands. Where wide water moats are used, islands can successfully restrain animals capable of great leaping activity (e.g., gibbons, chimpanzees, monkeys, etc.).

Retreat quarters or "dens" must be designed into the island. With large island exhibits, access tunnels are often included for the use of attendants.

D. Outdoor Cage Units

These are structures which are completely enclosed by fencing or bars. Barriers used are generally bars or fencing and with structural floors. Functional for most any animal except those which are not psychologically adaptable to the relatively close confinement characteristic of a cage. The disadvantages of visible cage barriers can be lessened by painting the bars or fencing a flat black or similar nonreflective color. Cages grouped together should be designed with variations of size and shape so that one may avoid the monotony of a continuous series of boxes. Also, the imaginative use of naturalistic props, such as trees, driftwood, rockwork, planting, and pleasing colors helps to avoid the cellblock effect of the old menageries (Fig. 3).

E. "Walk-through" Cages

A variation of the cage concept wherein the visitor actually walks through the cage (generally through double-doored "anti-escape" entry and exit compartments). A low pedestrian barrier keeps the visitor from entering the animal area. This display concept has the advantage of permitting closer contact between the visitor and the animal without a conspicuous barrier separating them. Such displays result in a more intimate and more esthetically pleasing experience for the visitor. Walk-through cages are applicable with any relatively harmless animal species whose ability to escape can be effectively controlled with the necessary visitor entry and exit arrangement. Confinement of the animals to the exhibit area can be encouraged by supplying the proper psychological needs.

F. Animal Pools

A body of water in which aquatic or semi-aquatic animals are shown, such as waterfowl, wading birds, otters, sea lions, etc. The pool may be enclosed by sheer walls, fencing, or other barriers. Underwater observation windows are extremely effective but require clear water for successful operation. Otters, seals, sea lions, penguins, and diving birds lend themselves particularly well to such display effects (Fig. 4).

G. Exhibit Buildings

Structures entered by the public in which the animals are maintained indoors, either seasonally or throughout the year. Often, outdoor cages, pens or grottos are located adjacent to a building and connect directly to exhibits inside the building. In this way, the animals may be shifted indoors, or out—according to the weather, the year around. Indoor exhibition may be desired for reasons of climate control (most animals of tropical origin) or for reasons of display effect where a darkened visitor gallery is essential (especially with glass-fronted displays).

Whenever possible it is desirable to restrict an animal display to a single exhibit area (either indoor or outdoor) for reasons of economy and to avoid practical problems of exhibition. In the latter case, the problem usually resulting from dual exhibit cages (indoor and outdoor) is that when animals have access to

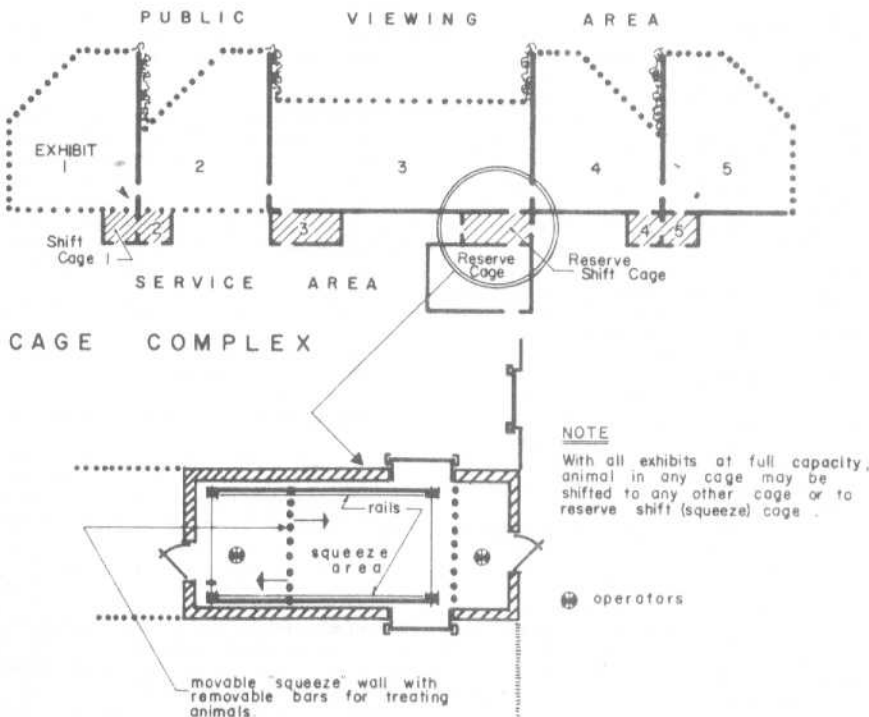

Fig. 3 A simplified plan for an outdoor animal cage complex.

both areas, the visitor must search both areas or miss the animal. Indoor cages can be designed so that the benefits of outdoor exhibition are brought indoors through the use of operational skylights, movable roofs, adequate ventilation, etc. Where adequately large indoor exhibits are impractical or too expensive, an effective compromise is to locate the indoor exhibit cage adjacent to the outdoor exhibit so that the visitor can view both from the same vantage point.

The variety of kinds of exhibit buildings is limited only by the imagination of the zoo designer. The following is a list of a few which have been either planned or built:

Mammals:	Other animals:
Monkey house	Insect house
Ape house	Reptile house
Feline house	Herpetarium (reptiles and amphibians)
Small mammal house	
Large mammal house	Habitat buildings:
Nocturnal mammal house	Aquarium (aquatic life)
Pachyderm house	Underground zoo
Aquatic mammal house	Rain forest
	"Habitat house" (several different habitat scenes exhibited)
Birds:	Miscellaneous:
Tropical bird house	Special exhibits buildings
Aquatic bird house	Nocturnal animal house
Penguin house	

Combinations of several of these into one building are frequently made.

Because of the exceptionally large crowds which visit zoos, details of design and materials selection must be carefully considered in planning the public areas of zoo buildings. Floor type is important as zoo visitor traffic is generally of a "shuffling" nature. Since zoo patrons frequently consume refreshments while walking, food spillage and the resulting hazards must be anticipated. Ramps (often imbedded with nonskid materials) are much preferred to steps. Adequate ventilation is mandatory and must be separated from animal areas. Some zoos include refrigerated air conditioning for visitor comfort. Traffic flow is another important factor and with careful planning should be as well-controlled and orderly as possible, preferably one-way on busy days. Clearly marked emergency exits are generally required by law.

H. "Visitor Cages"

This concept has been used most successfully on the game plains of Africa, but has recently been adapted to zoo use. It involves allowing the animals to roam free, or apparently so, in a large enclosure and placing the visitors in a closed vehicle such as a bus or a monorail car.

SERVICE STRUCTURES

A. Administrative

Depending of course on the size of the total zoo operation, the administrative facilities will vary in both area and complexity.

1. **Size** Three suggested categories based on the level of administrative complexity are discussed below:

Fig. 4 The otter display shown in sectional plan here permits the observer to view these animals underwater, above the water, or on the stone deck. The exhibit design is applicable to other species of aquatic mammals, various diving birds, and aquatic reptiles. (Fort Worth Zoological Association.)

a. **Minimum** A single administrative office may be incorporated with other service facilities in a combined zoo service building. Or, if a zoo exhibit building is already present or planned, the administrative office can be located in such a building for reasons of economy without adversely affecting efficiency.

b. **Median** A separate structure for administrative offices for the zoo director, secretary and other administrative personnel.

c. **Maximum** Enlargement of median facilities based on additional needs of a larger operation such as additional staff members, business office(s), library, meeting room (for staff, board and other small groups) and auditorium where audiences may be assembled for pretour orientation, educational activities, etc.

2. **Location** It is well to have the administrative building occupy a centralized location on the zoo grounds and be near or at the main entrance, the latter being where many administrative activities occur or radiate from. Direct access of this activity to a street and parking area outside the zoo grounds facilitates the administrative operation (Fig. 5).

B. Maintenance

This facility should have top priority in any zoo construction program and certainly precedes the acquisition of any live animal collection. Included here is animal maintenance concerning the daily feeding, cleaning, and care of the animal collection in addition to animal health requirements; buildings and grounds maintenance; accession, storage, and handling of supplies; and service facilities for personnel.

1. **Commissary** A function directly proportional to the size of the animal collection. Size of this facility should reflect anticipated growth and its design permit future enlargement. Prevention of rodent access to stored foods and ease of pest control should be incorporated in the design (Fig. 6). Basic requirements for this activity are as follows:

a. **Refrigerated Holding Facilities** Both chilled and freezer storage space is needed for food holding even in the smallest of zoos. Often, however, it is more economical for a small zoo, initially at least, to rent commercial freezer locker space rather than build and operate its own expensive facility.

b. **Kitchen** Diet preparation area with equipment such as grinders, choppers, mixers, blenders, juicers, stoves, ovens, scales, knife sharpeners, utensils (knives, steels, spoons, etc.) and containers (pails, dish pans, trays, etc.). Thawing facilities for frozen foods are especially useful.

c. **Storage** Nonrefrigerated food storage

including grains, commercially prepared foods, and canned goods. Dispensing hoppers should be designed into the facility and available to either the kitchen or diet delivery vehicles. Fodder materials need to be conveniently located. The combustibility of these materials must be considered in locating this facility.

d. **Location** The location of the commissary ideally should be central to all operations. In large institutions, it is often more practical to develop a main and centralized commissary facility where food is stored and prepared in bulk in addition to small departmental kitchens located in the main buildings. Ease of access for the regular deliveries of foodstuffs from outside the zoo should be provided.

e. **As an Exhibit?** A recent trend in zoo design is to install visitor observation windows in food preparation facilities so that the public can see the complexities involved in these formerly "behind-the-scenes" activities. Valuable byproducts of such installations are neater employees and more orderly and better kept facilities. Other applications of the same principle have been made with public view windows installed for specialized equipment such as filters and pumps. Even operating, post mortem and examination rooms and laboratories have been made viewable, resulting in excellent visitor reception with consequently improved public education to the total zoo operation.

2. **Hospital-Quarantine** Every zoo should have facilities where newly arrived and sick animals can be isolated from the rest of the collection, preferably in a structure completely separated from animal exhibit areas. Here also may be located the headquarters for the veterinarian, whether he be a consultant or on the staff. Facilities to be provided for are as follows:

- Quarantine section
- Sick wards with "squeeze cages" and outdoor recuperating pens
- Operating room
- Pharmacy and laboratory
- Post-mortem room
- Refrigerated holding boxes for specimens to be autopsied
- Equipment and supplies: microscope, centrifuge, autoclave, operating table, portable cages, restraining devices, surgical and medical supplies, laboratory ware, testing equipment, pharmaceutical refrigerator, etc.

Since babies must frequently be raised without a mother for one reason or another in zoos, the establishment of animal nursery facilities should be provided for. Often such activities are placed on public view as an exhibit. A human incubator is a useful piece of equipment in this facility.

Accommodation for egg incubators and chick brooders should also be included in zoo

planning. There are practical reasons for locating such in the animal health facility.

Depending on the size of the zoo operation several of the above activities can be combined into a single structure. It is desirable to either isolate this operation from direct contact with the public or locate it away from the visitor area (Fig. 7).

3. Reserve Animal Area Zoos constantly accrue animals for which exhibit space is either not presently available or when it is desired to isolate the animal from the public for purposes of breeding, holding for other zoos, etc. Also, some animal species may be exhibited seasonally outdoors and require winter holding quarters. Such animals, acclimated and healthy, invariably find their way into hospital sections or are scattered in rear service areas. A special reserve section built for the purpose is a practical and useful adjunct to the service facilities of a zoo.

4. Building and Grounds Maintenance This activity houses facilities for the conventional needs of repairs to buildings and grounds, minor construction jobs, grounds maintenance and horticulture. A shop area is a useful facility and should be included in even the smallest of

operations. Objectionable noises from the operation of power tools should be considered when locating this activity. Greenhouses to implement buildings and grounds beautification as well as planted exhibits should be included if needed. Storage facilities for tools, cleaning supplies, equipment, etc., should be located here.

Waste disposal is another important activity which should be included in maintenance planning. Incinerators are sometimes required for the disposal of dead animals.

5. Personal Facilities Employees' quarters with lockers, shower, restrooms and dining area are necessary for any operation. Not only is employee morale bolstered but personnel can be expected to be neater and more presentable when such facilities are available.

6. Combinations For a small zoo most of these maintenance functions can be efficiently designed into one central structure.

7. Location Due to the constant activities of pickup, delivery, and disposal of materials involved in the various maintenance operations, the structure or structures housing them should be located with direct access to an

"outside" or off the zoo grounds street. Service drives leading from maintenance areas to the various zoo facilities should be included in the grounds plans, preferably isolated as much as possible from public areas.

C. Public Services

Any operation which attracts the tremendous crowds which zoos engender must have adequate facilities which cater to the personal needs of visitors, as well as provisions to handle emergencies and maintain security.

1. Restrooms Inadequate and/or unclean restroom facilities do more to give a public institution an unsatisfactory reputation than any other condition—a fact which service station operators have been aware of for some time. Zoos are well advised to include the installation of toilets especially designed for children due to the large number of youthful visitors. Urinals for female visitors are also being utilized in some public restrooms.

2. Special Services Problems of crowd control are common to every zoo and proper planning must take the following factors into consideration:

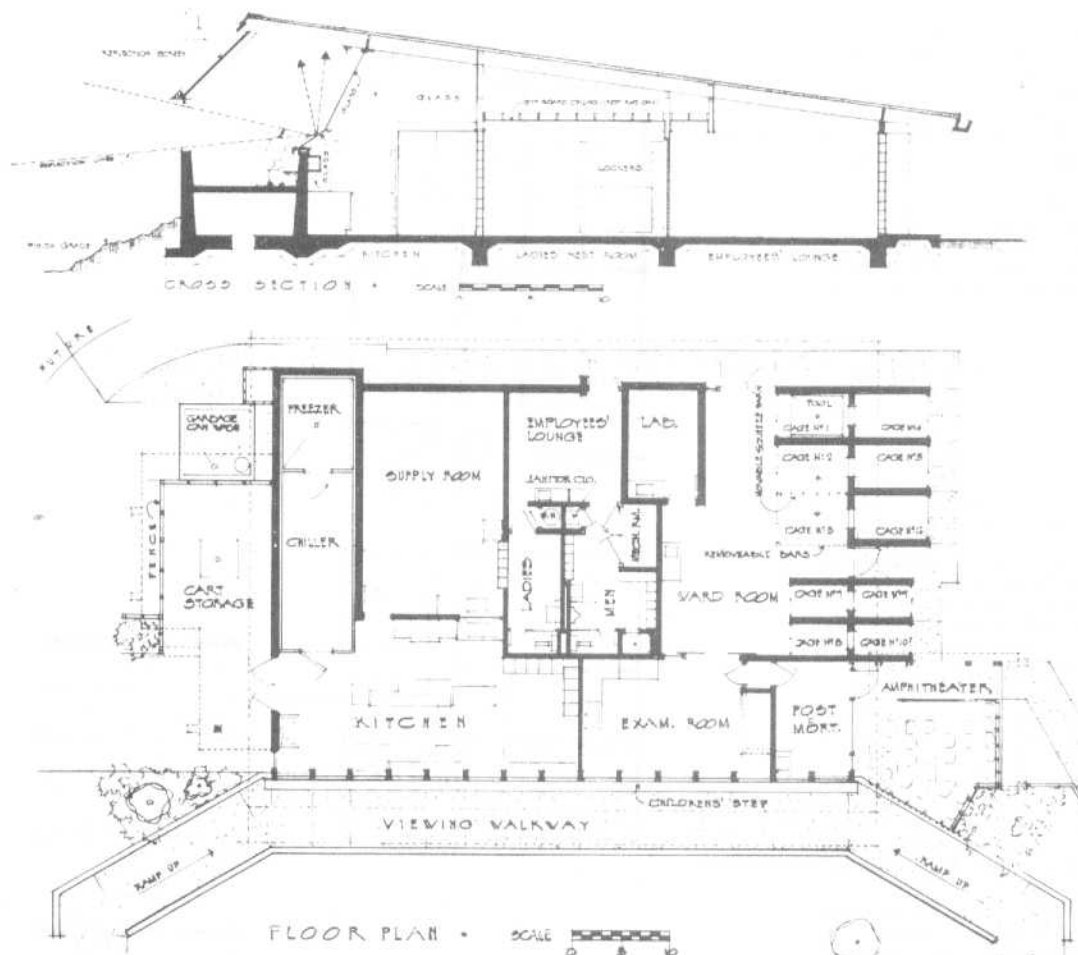

Fig. 5 The service building shown here includes commissary facilities on the left, attendants' quarters in the center rear, and animal health on the right. All activities along the building front are viewable by the public from the elevated and hooded ramp. The specially designed hood and double tilted glass eliminates reflections and yet maintains an open feeling. The kitchen area (lower left) shows the large observation windows. The amphitheater (below right) adjoins the post mortem and operating room. Here biology classes observe operations and autopsies and may take tissue specimens back to their school laboratories for further study. A two-way public address system permits question and answer interchange between the veterinarian and class. (Fort Worth Zoological Association.)

a. Public Address System For locating lost children, lost and found items, making special announcements (e.g., animal feeding times, animal demonstration and acts, etc.) and often the playing of background music.

b. Emergency Properly supplied first-aid facilities with trained personnel available should be a part of every zoo. Special instructions for the handling of intoxicated visitors, heart attack and heat victims, etc., should be available to all personnel.

c. Transportation Many zoos install vehicular systems to take visitors from one point to another or for tour or sightseeing purposes. Tractor trains, animal-drawn carts and rides, rail trains, buses, and even an overhead monorail are a few examples currently in operation in zoos. Generally, a public address system is available on such conveyances which permits lectures during tours. Availability of stroller and wheelchair rentals are also a convenience to zoo visitors.

3. Concessions Several pamphlets published by the National Recreation and Park Association are available concerning this area of design and operation. In general the following basic concessions have proven to be effective in zoos:

- Refreshment stands for minor food and beverage items
- Cafe and restaurant facilities
- Vending machines for beverages, snacks and special animal foods
- Souvenirs, gifts, and numerous educational items zoologically oriented (books, pamphlets, maps, post cards, models, etc.), jewelry, photographic film, rental cameras, etc.
- Parking lot fees
- Transportation systems

Profits from zoo concessions can be an important factor in subsidizing zoo budgets, thus decreasing the zoo's dependence on tax revenues.

GENERAL

A. Display

The difference between a menagerie and a zoo might be defined as follows: a menagerie is simply a collection of animals on public exhibition. A zoo is an educationally planned and oriented animal display presented to the visitor in the most esthetically pleasing, interesting and naturalistic context practical. Several display factors contribute to the qualities of a zoo and are listed as follows:

1. Signs and Labels These perform several functions and can be of the following four major varieties:

a. Natural History Common name, scientific name, habitat, geographic range and interesting natural history information. Where several species are exhibited together, these signs should be illustrated for easy identification.

b. Visitor Information Signs which advise the visitor of opening times for exhibits, acknowledgment of donations, feeding times, etc.

c. Visitor Instruction Signs for protection of animals, such as "do not feed," and warnings of potential dangers to visitors, such as crossing guard rails, entering off-limit areas, etc.

d. Directional Signs directing the visitor to exhibits, buildings, service facilities, etc.

Fig. 6 The commissary shown in this plan permits an efficient operation for food storage and preparation. Facilities are provided for slaughtering food animals. (Cheyenne Mountain Zoological Park, Colorado Springs.)

Fig. 7 A combination administration and hospital building. Facilities include a library, offices, quarantine and ward rooms, laboratory, pharmacy, and winter quarters. Zoo buildings, especially service facilities, require a careful selection of construction materials, particularly those which will stand up under constant humidity and abrasion of daily cleaning. (Franklin Park Zoo, Boston.)

2. Special Technique The imagination has few limits with respect to animal exhibition. Such features as special lighting, sound effects and the like have been favorably received by the visiting public. Museum displays which supplement the live animal exhibits are extremely effective in zoos and enhance their educational value. Visitor activated pushbutton exhibits are excellent. Also, slide and film projectors which illustrate an animal activity, life cycle, or other such features, otherwise impossible to demonstrate in a live exhibit, are most effective display supplements.

3. Demonstrations With many animals it is possible to go beyond the concept of the "animal sitting in the cage." The presentation of demonstrations showing specific behavior activities may be done by a variety of techniques. Some of these demonstrations must be planned with an adequate number of animals available so that the welfare of the animal subjects is not compromised. A few examples of such exhibit supplements are as follows:

- a. Electric fish demonstrations
- b. Spitting (archer) fish feeding demonstration
- c. Rattlesnake rattling and striking
- d. Cobra hood-forming demonstration
- e. Animal weighings on built-in scales
- f. Conditioned-reflex demonstration
- g. Otter slides
- h. Porpoise and fish sounds picked up by underwater microphones
- i. Observation chick incubators
- j. Microprojection of invertebrates
- k. Any scheduled special feeding

Demonstrations such as the above represent perhaps the greatest potential today in the development of educational zoo display.

B. Visitor Participation

Any design feature which establishes a closer relationship between the visitor and the animal is generally to be desired. Care must be taken, of course, that the welfare of neither the animal

nor the visitor is endangered. For example, public animal feeding of a proper ration is a good revenue producer and, to an extent, a budget saver. Coin-operated vending machines are available which are manufactured for animal wafers. Coin-operated or pushbutton animal acts are also of interest. A number of commercially available installations have been developed for providing prerecorded information for zoo and museum visitors through "talking labels," transistorized receivers with earphones and similar devices. These devices increase the effectiveness of the zoo's educational program while also adding a personal touch to the exhibits which printed labels do not provide.

Since amateur photography is widespread, it behooves the zoo planner and operator to facilitate such activity as much as possible. Signs with meter checked camera settings for highly photographed exhibits, public dark rooms for film changing, and of course a film sales desk are facilities which zoos can make available to the photographer.

Recreation and Entertainment

AQUARIUMS

The Need and Concept

An aquarium built almost anywhere will prove to be a popular attraction. Nevertheless, to be successful, whether financially or in terms of education or recreation, it must be sited where a real need exists.

The concept of the aquarium, what it will be and do, must be determined early. Within the funds available, what usual and what special features will be included must be decided upon.

An initial simple design should be prepared which presumably will provide adequate space for the expected visitors and will also provide the necessary operating areas. These must then be considered with knowledgeable persons and be modified as required. If the aquarium is to be more than a house for living aquatic animals and plants, an exhibit specialist should be at hand to design presentations to meet the objectives of the institution.

Public aquariums are leaning more and more toward educational recreation for their visitors. It is felt that a mere lineup of tanks containing specimens identified by photographs, names, and range may be interesting, but is not sufficiently informative. Groupings of specimens may be made to illustrate environmental preferences, means of locomotion, sight, hearing, food habits, schooling, use by man, and any number of other interesting and informative themes. If these are properly presented, the visitor will unknowingly absorb and retain much knowledge of aquatic life.

Planners should, then, include in the design particular configurations of tanks, in separated groups, as a means by which a theme can be effectively carried to the audience. Contributing information can be furnished by pushbutton filmstrips, guidebooks, and by lighted legend boxes.

The Planners

We shall assume that the promoters of the aquarium have the necessary financial backing and that they realize that at least 60 per cent of the cost will be for facilities, equipment and design, most of which are peculiar to aquariums and are not visible to the public.

The promoters have a site that appears to be suitable. It should be readily accessible by both public transportation and private vehicles, and should, if possible, be easily reached by tourists. Adequate vehicle parking in the area is desirable.

The most vital factor is the water supply. Usually the promoters are not competent to judge this essential ingredient, the quality of which must be known before the project can be further developed. Too often promoters assume that the water is of good quality and of sufficient, continuous volume.

At this point in the planning the promoters

should seek professional advice, both as to the quality of the water and the volume required for the proposed facility. From here on the planning staff should include individuals competent in the aquarium field.

Designing for visitor guidance will be based upon the building and site size and an estimate of the expected visitor load. More often than not the funds available for a public aquarium will dictate the size, regardless of expected visitations. If the site is large enough, the original design may provide for future expansion.

It is desirable to have a flow pattern for visitors. Design can quite readily lead the visitor into the desired path in most situations. Upon entering, a visitor will generally turn right, provided no attractions draw him elsewhere. By placing display tanks at an angle, with the viewing glass facing the oncoming visitor, he will normally proceed in that direction. Open-floor exhibits can serve as shields and also continue to draw the visitors along the desired path (Fig. 1).

Fig. 1 Visitor's flow pattern.

Monotony is to be avoided in the placement of display tanks. They should not be lined up like railway car windows. All of them should not be set at an angle. Alcoves and jut-outs will provide variety and surprises, and can serve as dividers between special exhibits. Variety also serves to orient the visitor.

Handrails to keep the public about 3 ft from the viewing glass may be desirable. Opinion

is divided among aquarists regarding rails. When large numbers of visitors are present, a rail keeps them back from the glass and permits more people a better view. On the other hand, close inspection of small organisms is then not possible. (See Figs. 2 and 7.)

A step-up for small children is often provided. This usually is about 1 ft high and 1 ft wide, and should be part of the building structure and continuous.

The Operations Area

As previously stated, planners of aquariums often consider the facility only from the visitor's viewpoint. They do not realize that the welfare and attractiveness of the specimens and minimum costs for operation and maintenance depend upon the attention given to behind-the-scenes design.

The immediate work area behind the display tanks may be considered first. The work-area floor should be about 3 ft higher than the public area floor. This is dictated by the height of the average visitor looking into the approximate center of the viewing glass of the average large display tank. Most display tanks are placed on the floor of the work area. Obviously, very small and very large tanks will have to be placed differently. Tanks should be placed to permit ease of cleaning by aquarists.

Holding tanks to receive new specimens for quarantine and space to hold surplus or sick specimens should be placed along the rear wall of the work area or in any other convenient locations. Each of these holding tanks should have its own recirculating system. The total holding capacity should be equal to about one third of the display volume but may vary considerably, depending upon the sizes of display tanks and specimens as well as the mortality rate and replacement need (Fig. 7.)

All quarantine tanks should be provided with drain valves to permit rapid drainage after treatment procedures. All tanks should have removable pump screens.

Many aquarists feel that practically all

Fig. 2 Plan of tank gallery.

Aquarium Design Criteria, Drum & Croaker, National Fisheries Center and Aquarium, U.S. Department of the Interior, Washington, D.C., 1970.

healthy specimens ought to be on display since they use space when held in reserve and require the same care as specimens on display. Nevertheless, too few quarantine or treatment tanks can greatly hamper operations. The exhibit/holding ratio should be carefully considered.

The various main supply pipes from the reservoirs should extend around the aquarium over the display tanks. These should be a minimum of 7 ft above the work-area floor and should have frequent tap valves from which, by flexible hose, replacement water or a continuous flow may be fed to the tanks, depending upon the system. It is important to have shut-off valves conveniently located along the major supply lines to facilitate plumbing repairs.

To reduce the possibility of accidental flooding to a minimum, automatic cut-off switches, built-in overflow drains, and failsafe devices should be planned in connection with tanks and reservoirs that are periodically drawn down and refilled.

All electrical appliances and equipment, including connector boxes, must be grounded. Outlets should not be located near the floor. Fixtures over the tanks should be protected to avoid breakage and possible danger to personnel working in water. Poles attached to brushes or other cleaning devices should be of wood or other nonmetallic material.

Natural light should be held to a minimum, unless completely controllable. Natural light

promotes algae growth on interiors of tanks.

A flexible lighting system over each tank should include the capability of being lifted out of the way when cleaning tanks or feeding specimens. Sufficient waterproof outlets should be provided for auxiliary or special lighting.

A clear passageway about 6 ft wide should extend along the back of all display tanks in order to permit the easy transport of tanks, incoming specimens, etc., by fork-lift truck or four-wheel flatbed. No stairs or other obstacles should be located in this passageway.

The surface of the work-area floor should have a nonskid finish. Floor drains with sand traps are absolutely necessary and floors should be sloped to drains. Water-resistant materials should be used in all places adjacent to tanks.

Storage space for tools, nets, chemicals, and other items in frequent use should be provided. Refrigerators often are convenient for the storage of special foods, and may reduce trips to the food preparation room.

Stairs should be placed conveniently from the work area to the public area, with lock doors. Small wall desks may be provided for record keeping.

Deep washbasins with hot and cold water and towel boxes should be located conveniently in the work areas. Also, suitable containers for net sterilization should be provided.

Centrally located and convenient to the live

exhibits should be the grouping of loading dock, food preparation room and freezer, offices for the biologist and chief aquarist, a room for the shipping and receiving of live specimens, and a crew room with showers and toilets. Space for the chief engineer and control and monitoring panels should be provided. The size of each of the foregoing, as well as the necessity for offices and crew room, will depend upon the size of the aquarium and the number of personnel involved in operations.

The above can be located on either the work-area level or the public-area level. If the latter is the case, a ramp should extend from the loading dock area to the work level. It is also desirable to have easy rolling access to the public area and to the administrative offices.

In any aquarium a two-way intercom system is very important.

The work area should be separated acoustically from the public area.

Interior windows may be desirable to permit visitors to view the more interesting operational features.

By JAMES W. ATZ, Associate Curator,
The American Museum of Natural History

Water Quality

The chemical condition of the water in which fishes and aquatic animals without backbones (invertebrates) are kept is vital to their health. Anything suspended or dissolved in the water comes into the most intimate contact with these animals, mostly through their gills, and there is little they can do to keep harmful substances from entering their bloodstream or body. For example, only two parts of copper dissolved in a hundred million parts of water can kill some fishes within 24 hours, while acutely toxic concentrations of pesticides like Endrin need have a strength of less than one part per billion. The invertebrates are even more sensitive than fishes.

In order to keep animals as sensitive as this alive in captivity, there is only one safe rule to follow: all aquaria and other parts of water systems must be made of chemically inert materials.

The source of any water that is to be used in aquariums must be scrutinized to make certain it always has the proper chemical composition and never contains substances harmful to the exhibits. Ordinary standards of water purity are not adequate because perfectly potable fresh water or seawater, perfectly safe for bathing, may be deadly to fishes and aquatic invertebrates. As far as their water supply is concerned, these animals are much more delicate than man. Frequent troublemakers in municipal tap water are chlorine, excessive hardness, and brass or galvanized piping. A single small metallic fixture can quickly bring about the death of fish when the water running through it is soft.

As far as the aquarium's visitors are concerned, the only necessary water quality is clarity, so that they can easily see the exhibits. For large tanks (500 gal or more) the water must be very clear indeed; the water of some municipalities contains colloidal clay, and although it looks crystal clear in small tanks, its milky appearance in large ones makes viewing through it quite unsatisfactory. (Animals may live in such cloudy water without any difficulty, but water that is cloudy from the

Fig. 3 Cross section through coral reef tank.

AQUARIUMS

presence of myriads of bacteria is unsatisfactory for both visitor and exhibit animal, although for different reasons.)

In some aquarium water systems, the water is used only once and is then discarded. These are called *open systems*. *Closed systems* are those in which the water is recirculated, being used over and over again.

Sometimes it is necessary to treat the water as soon as it enters the aquarium building, usually by filtering it. Natural seawater should always be filtered before being put into reservoirs or closed systems of any kind in order to remove the tiny animals and plants (plankton) that inhabit it. These floating mites cannot live under the conditions of captivity and when they die, they decompose and temporarily make the seawater toxic to larger forms of marine life. Even filtered seawater "rots" to some

extent and may have to be stored in the dark for as long as 6 weeks before becoming fit to use, particularly in small tanks.

For the great majority of exhibits, however, fresh, filtered seawater may be used without delay if it has not originated from polluted sources and if each water system contains at least 1,000 gal. On the other hand, untreated natural seawater can be used in *open* systems provided it is clear enough not to obstruct the view of the exhibits. An important advantage of this kind of arrangement is that it makes easy the exhibition of plankton-feeding animals, which subsist on the small plants and animals they strain out of the water.

Unless the aquarium can be built near a dependable source of water of the proper quality and sufficient quantity, closed water systems will be a necessity, but water that

is used over and over accumulates waste products from the animals living in it, and as time goes on, the concentration of these substances becomes intolerable. Their removal, however, presents special problems.

Aquarium animals, just like terrestrial ones, must consume oxygen to stay alive and at the same time must get rid of the carbon dioxide they produce. If the water in which they find themselves has either too little oxygen or too much carbon dioxide, they will die. Fortunately, the atmosphere provides an unlimited supply of oxygen and can take up unlimited amounts of carbon dioxide—at least the small amounts produced by aquariums. Therefore all that needs to be done is to expose enough of the aquarium water to air above the vessel so that the two gases will be exchanged at a sufficiently rapid rate. This is most easily done by

Fig. 4

the use of aerators, although circulating the water and otherwise agitating it is also very helpful. (See Fig. 4.)

The animals' other wastes are not so easily disposed of, however; in fact, no economically feasible way has yet been devised to remove them from aquarium water. Most important of all is ammonia. This is the principal waste product in the urine of fishes, and these animals excrete ammonia through their gills as well. Ammonia is also the principal excretory product of aquatic invertebrates. Other waste products, such as urea, are broken down into ammonia by bacteria in the water. In addition, ammonia is produced when bacteria bring about the decomposition of fecal fish wastes as well as any uneaten food or plants and animals that have died in the tank. It would not be far wrong to state that every bit of food put into an aquarium, except that utilized in the growth of its inhabitants, eventually turns into ammonia.

Ammonia is exceedingly toxic to almost all fishes and invertebrates. For example, trout living in water with as little as six parts per billion of ammonia show abnormal gills. Even freshwater pond fishes, which are much less sensitive to ammonia than trout or coral-reef fishes, should not be exposed to concentrations of more than one part in ten million of water.

At the present time, there is only one economical way to avoid ammonia poisoning in closed aquarium systems, and this is by taking advantage of the bacteria that change ammonia into nitrate (by oxidation), a chemical that is much less harmful to aquatic animals. These nitrifying bacteria occur naturally in all aquariums and water systems, but not in large enough numbers to quickly convert the toxic ammonia into relatively harmless nitrate. In a well-managed tank, these bacteria thrive on the walls and other surfaces, but not in the water itself, because they must be attached to some kind of solid material in order to grow and multiply. There are not enough surfaces in an aquarium to provide "homes" for sufficient numbers of nitrifying bacteria to keep the concentration of ammonia as low as it needs to be, that is, virtually zero. One of the principal functions of a filter is to provide living space for nitrifying bacteria, and countless numbers of them cover the grains of sand or gravel of the filter bed. In the future, other ways of eliminating ammonia may be found, but biological filtration is now the only practical way to do so.

In addition to the solid surface they require, nitrifying bacteria need oxygen; the water should be aerated both before and after filtration—afterwards in order to replace the oxygen used up by the filter bacteria. Nitrifying bacteria are slow multipliers (as compared with many other bacteria), and cold temperatures, acid waters, high salinity, and lack of calcium slow them down even more. Whenever an aquarium or a water system is put into operation, the number of animals put into it ought to be limited until the filter has acquired its full complement of nitrifying bacteria. A "healthy" filter is essential to a "healthy" closed aquarium water system and vice versa.

The longer the aquarium or water system is in operation, the greater the amount of nitrate that accumulates in the water. Although certain aquatic bacteria (denitrifiers) change nitrates into nitrogen gas and thus eliminate the nitrogen from the system, this process does not take place rapidly enough to prevent the buildup of nitrate in aquarium water. More-

over, there are other less well-known substances that accumulate in the water in which animals are living. None of these is at all as toxic as ammonia, but they do have an inhibitory effect, especially on marine invertebrates. The only practical way to get rid of them, at the present state of aquarium technology, is by replacing part of the water at regular intervals. This is the procedure used by home aquarists who want their fishes to reproduce. By keeping the concentration of nitrates (and undoubtedly other inhibiting substances that were not measured as well) below 10 parts per million with regular replacements of fresh seawater, the London Aquarium has been able to maintain marine invertebrates it otherwise found impossible to keep alive.

Another cumulative change that takes place in aquarium water is an increase in acidity. Oxidation is a process essential to all life, and oxidation is an acid-producing process. Aquatic animals produce carbon dioxide, which becomes carbonic acid in water. All of their other waste products are eventually oxidized by bacterial action, and this, too, produces acid. In order to prevent the aquarium system from suffering from acidosis, it must be alkalinized. This is absolutely essential for closed seawater systems and is usually accomplished by keeping the water in very close contact with some form of calcium carbonate (coral sand, calcite, marble chips, bivalve shells).

Proper aquarium water quality depends primarily on the following factors:

- Chemically inert material
- Suitable source of water
- Adequate circulation, aeration, and filtration
- Cleanliness, achieved mostly by avoiding overcrowding and overfeeding

- Control of waste end-products by filtration, alkalization, and dilution

Water Systems

The water system includes, in whole or part, the incoming line, a clarifying or sterilizing unit if required, storage reservoirs, the pipelines furnishing types and temperatures of water serving the display tanks, the display tanks, inflow and outflow and drainage, and filters.

Piping should be of nonmetallic materials. Water should come in contact with metal only as absolutely necessary. Metal or other piping may be used to serve cetaceans, seals, penguins, and aquatic reptiles, but expensive replacement may be necessary because of corrosion. (See Figs. 4 and 5.)

1. Open system (use and waste). This method is the least complicated and least troublesome provided an adequate source of excellent disease-free water is available. The requirement that metal not come in contact with water may not be quite so important here, as the animals are exposed to water that has passed over the metal only once and as the toxicity potential decreases due to the formation of inert oxides, etc., on the interior of metal pipes, thus forming an insulating barrier, but corrosion is a factor to be considered.

Economics must be considered when water is to be discarded after one use. As a general rule of thumb, the average display tank of specimens loaded at the rate of 1 lb. of fish per 100 gal of water should have a turnover or replacement rate of one volume each one to two hours. If the gallonage of all display tanks is 100,000 gal, a flow of 50,000 to 100,000 gal per hour would have to be maintained. Thus,

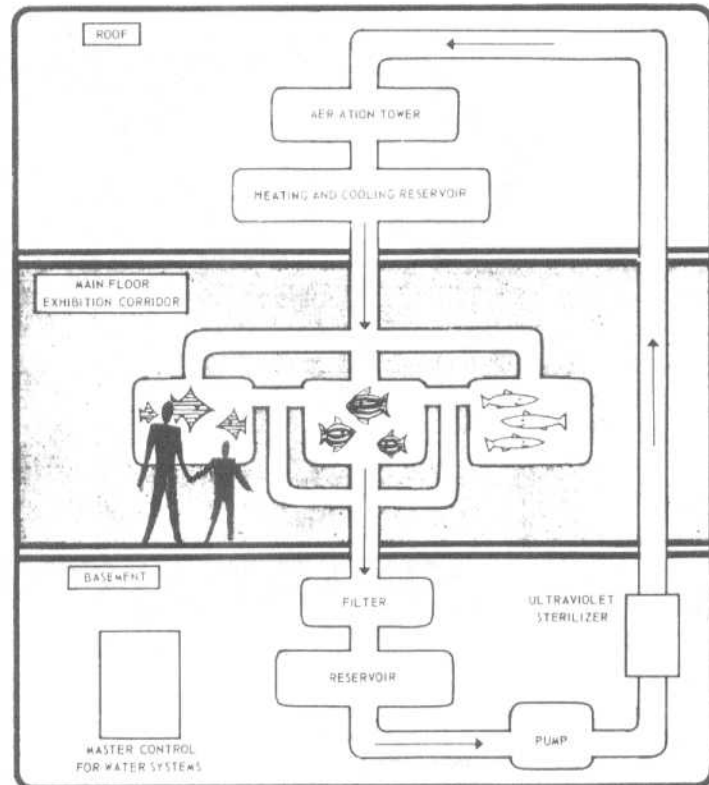

Fig. 5 Simplified diagram of the aquarium water system.

Recreation and Entertainment

AQUARIUMS

Fig. 6 Typical vanishing side wall tank installation.

Fig. 7

1.2 to 2.4 million gal would be required each 24 hours. An added cost would arise if some waters had to be heated or cooled.

When water is used only once and discarded, the rate of turnover usually need not be as great as in closed systems, as waste products from the specimens are continually carried away.

It should be noted that the rule of thumb cited above is just that. Many species of fish can be loaded heavier, and some species, particularly invertebrates, may require a more rapid turnover of water.

2. Closed system (recirculating total system). Water continuously enters the display tanks and the overflow returns to the reservoirs after passing through filters. In theory, this method requires only the replacement of water lost by evaporation or in the process of cleaning a tank or backwashing a filter. However, seawater should be replaced at the rate of one-third of the total volume every two weeks, if possible. If this cannot be done, monitoring of nitrite, nitrate, and urea buildup becomes very important.

One serious disadvantage in a closed system is the real possibility of disease organisms from one tank being carried to all tanks. Filtration will not remove many of these. Ultra-violet radiation or passage through a reverse

osmosis process, however, is effective in removing or destroying organisms both desirable and undesirable. Reverse osmosis cannot be used with salt water.

3. Closed system (recirculating individual systems). Each display tank is provided with its own recirculating water system. Filling and minor replacement is from the main supply lines. In operation, the overflow passes through a biological filter and is pumped back to the display tank. Desired temperature range can be maintained by cooling or heating units placed in the filter or line.

In the recirculating systems, the main supply lines of water, preferably overhead, also are continually circulating at a low rate to preclude dead water and the growth of organisms in the pipes.

The plans for the National Fisheries Center include the above system (3). The city water supply contains traces of zinc and copper, detergents and chlorine. After all display and reservoir tanks are filled (approximately 3.5 million gallons) the replacement water estimated to be required is 100 gallons per minute. It is planned to pass this incoming water through the reverse osmosis process to remove the metals and detergents. The chlorine will be removed by aeration or charcoal filtering.

Display tanks of up to 2,000 gal can, for some species, be recirculated through bottom filters with water circulation controlled by air-lift pumps.

In recirculating systems it is desirable to replace at least 10 percent of fresh water and at least 40 percent of salt water each month to avoid a buildup of harmful substances. Usually a greater amount than this is replaced when the display tanks are regularly cleaned and filters backwashed.

Display Tanks

Tanks for the display of aquatic specimens are expensive. Materials in tanks for seawater must be more carefully chosen than for fresh water. Nevertheless, all tanks should be made of inert material to the greatest extent possible.

Ideal tanks are those that are least costly, light in weight, readily altered or drilled, inert in seawater, with hard and smooth interiors, among other things. No currently available materials from which tanks may be produced have quite all the foregoing desirable features. For smaller tanks (up to about 2,000 gal), fiber glass or plastic-impregnated plywood appear to be quite satisfactory.

A number of companies manufacture fiber

AQUARIUMS

Fig. 8

glass aquaria or holding tanks. Moreover, some of these will fabricate to specifications. It is desirable to plan to install tanks of standard sizes, preferably those that are available "off the shelf" or for which fiber glass-fabricating forms are still available.

Fiber glass is completely inert, is light in weight, and can be readily altered and drilled. Some experience by aquarium personnel will permit them to make repairs. It is quite possible, with an experienced technician, for an aquarium to fabricate its own tanks of reinforced fiber glass.

For larger tanks, reinforced concrete, steel

plate, or some other substantial and suitable material will be required.

Concrete tanks should never be poured as an integral part of the building. Each such tank should be an independent unit, capable of being broken up and removed without damage to the building.

The design of tanks should consider the problems of drainage, cleaning, viewing, etc. Some tanks, because of the specimens to be held therein, may require special features, e.g., scuppers at the surface to remove oily film produced by some foods. Rapid drainage is desirable. It is preferable that gravel or sand

not touch the viewing glass. Disappearing side walls may be desired (Fig. 11.)

All concrete and metal surfaces should be coated with an epoxy sealer. This will continue to seal the inevitable hairline cracks in concrete, and thus prevent seawater (particularly) from attacking the reinforcing iron. (If possible, Monel bars should be used.) The seal also inhibits the growth of algae. Color may be added to the epoxy. Epoxy may also be used with sand to provide skidproofing for wet floors, ramps, etc. Careful application of epoxy paints over concrete will prevent blistering.

INDOOR TENNIS BUILDING

INDOOR COURTS AND BUILDINGS

Number of People Per Court

An indoor facility generally has a capacity of 125–150 members per court, since the indoor court is available at least 14 hours per day, 7 days a week. There are some players who show up infrequently, while others wish to play 5 hours or more per week. Most sets played are doubles and require four people per period.

Site Selection

As previously suggested, a site should be selected which is reasonably level to avoid excessive grading problems. It should be sufficiently large to allow expansion of the number of tennis courts, the club facilities, and parking and still allow sufficient room for required setbacks of the building from the lot lines. The site should be properly zoned for tennis establishments, located as close as possible to the active tennis playing group in the community, preferably within 15 minutes driving time. Availability of utilities at low cost is highly desirable. Restrictions on height and types of construction should also be considered when choosing the site.

Clubhouse Facilities and Layout

It is generally more economical to place courts side by side if there are less than six. It then may be feasible to place three courts side by side and the additional courts end to end with the first three. Of course, the shape of the property may dictate the shape of the building to be constructed.

The person in charge should be able to see everyone who enters or leaves the building and

goes to or from the locker rooms; it is difficult to see what is happening more than four courts away. A side-court control point is preferred. This position allows the person in charge to see all that is happening without interfering with play.

It is highly desirable to separate the teaching court from adjacent courts by a divider net to prevent balls from interfering with play in progress. The divider net can be located directly over the outside alley line of the teaching court or there should be a minimum of 10 ft on each side of the divider net to the nearest outside alley line.

Players should be able to get from locker rooms to their court out of sight of players on adjacent courts. Men's and women's locker rooms generally contain seven to eight lockers per court. Generally 1 to 1½ showers per court is sufficient in the men's locker room; ¾ to 1 shower per court (with private dressing booth) is generally sufficient for the women's locker room.

Building

The tennis court building should be 120 ft in the clear to accommodate the length of the tennis court and the space behind the end lines. The walls behind the courts should be a minimum of 16 ft high and the center of the building over the net should be a minimum of 35 ft in the clear. For safety any structural members projecting into the playing area should be padded with foam rubber or other shock-absorbent material from a point 18 in above the floor to a point 6 ft above the playing surface.

Court Surfaces

All surfaces used outdoors can be used indoors. However, certain types of porous courts require the addition of moisture on a daily basis. Adding moisture to the air will make it humid and may create condensation problems on the structure in the colder climates unless adequate precautions

are taken to insulate the outside surfaces. Because frost is not a problem indoors, the court base can probably be reduced in thickness to save money. Indoor courts should also be level.

Hard courts may be used for other purposes, and porous courts can be covered for other uses or repaired if abuse is minimal. But nonporous cushioned courts *cannot* be used for any other purposes.

Lighting

Lighting may be provided by incandescent, fluorescent, mercury vapor, or quartz lighting fixtures. Lighting intensities should be above 50-foot candles for tournament and club play and above 30 foot-candles for recreational play. It is desirable to shield the player as much as possible from a direct view of the light source, and some lighting should be directed upward to reduce the contrast between lighting above and below the lighting fixtures. When louvres are used under fluorescent lights, they can be protected by an expanded metal screen. Natural lighting may create more problems than it cures.

Other Considerations

Gas or electric radiant units, hot-water perimeter fin-tube units, and warm-air distribution duct systems provide the most uniform heating. Unit heaters can also be used. If air conditioning is to be considered, a duct system might be utilized for both heating and cooling.

Ventilation should meet local building codes. If no code exists, it is considered good practice to provide ½ to 1 air change per hour.

The ceiling of the court area should be a light color. There should be no contrasting colors for structural members. The background behind the courts should be a medium or dark color for 8 to 10 ft above the playing surface.

Recreation and Entertainment

SPORTS ARENAS

By ROBERT L. KNAPP, AIA, Charles Luckman Associates, New York

There are three primary sets of requirements which the sports arena designer should clearly define and then keep in proper focus during the design/planning process. They are:

1. General planning requirements
2. Spectator requirements
3. Operation/management requirements

On occasion, conflicts will develop among these criteria as the attempt is made to find the optimum solution to a particular set of problems—as for example between providing a maximum seating capacity for a large variety of events and perfect sight lines for all spectators. As these conflicts develop, the designer should be alert to them and promptly communicate alternatives to his client. In this manner a serious evaluation can be made of the alternatives at the appropriate stage of the design/planning process, thus allowing the flow of work to proceed smoothly with minimum wasted effort.

GENERAL PLANNING REQUIREMENTS

Projected Uses

Among the first program criteria to be determined regarding multipurpose arenas is the list of projected uses or events which are intended to be booked into the arena. Many events require their own unique features or support facilities which if not included in the original design and construction prove very difficult and costly to provide at a later date (e.g., inserts in playing floor surface for anchoring circus rigging). Some also have fixed dimensional or space requirements which must be accommodated and checked for sight lines. A list of the more common events currently being held in multipurpose arenas follows (Figs. 1 to 6):

Ice hockey	Horse show
Basketball	Rodeo
Boxing/wrestling	Bicycle racing
Indoor track	Rock concerts
Tennis	Stage events
Circus	Conventions
Ice show	Exhibitions
Roller derby	

Seating Capacity

The establishment of maximum seating capacity should be carefully evaluated prior to start of design. Several factors are important in making the determination including:

1. Market area
2. Professional franchises
3. Sponsor/owner
4. Budget
5. Viewing distance limitations

The market area, whether it falls within a large metropolitan region or a small college town, should have an influence on determination of optimum seating capacity. The overall size of the market area radius will depend not only upon total area population but largely on available highways and mass transit facilities. The nature of the potential audience must also be analyzed as to income levels, spending

habits, and recreational preferences. The availability of competing arenas or other attractions will also be a factor.

The growing popularity of professional sports in the United States is perhaps the biggest impetus to the construction of new arenas. The professional hockey and basketball leagues require prospective new franchise owners to provide arenas of specified capacity and quality. These regulations should be checked specifically at the start of any design program, but in general terms of capacity they have specified 15,000 to 18,000 seats.

The nature of the owner or sponsor of any new arena will have some influence on the capacity decision. College or university arenas, except those with a history of top basketball teams and enthusiasm, will tend to warrant a

capacity of 12,000 to 15,000 seats. A municipal arena with one or more professional teams as tenants will tend to be larger as stated above. Also arenas built privately as profit-making ventures will tend to be even larger, as well as to book a wider variety of attractions. Their economic success depends largely on creative and energetic promotion to keep "dark time" to a minimum. The operator of a municipal arena will be under somewhat less pressure to show a profit as the subsidization of operating deficits can be rationalized against the peripheral revenue an arena may bring to a locality through increased property values and business income from arena patrons.

In cases where an overall construction budget has become fixed prior to any physical planning or programming, this alone may

Fig. 1 Hockey.

Fig. 2 Basketball.

Fig. 3 Circus.

Fig. 4 Track.

Fig. 5 Stage events.

establish the maximum capacity. Construction costs and circumstances vary too widely to attempt to quote here any cost per seat figures that would not be misleading. Estimates should be made at the completion of any schematic solution to test the scheme against the budget target. If reductions must be made, they should be balanced between capacity and quality. Too often it is a shortsighted decision to hold on to capacity at the sacrifice of material and systems quality which will have long-term penalties in operating and maintenance costs.

Possibly the most relevant factor in the determination of maximum capacity is that of optimum viewing distance. The limitations of normal visual acuity make any seating falling outside a radius of 200 ft from the center of action increasingly marginal. Although the Houston Astrodome and other planned enclosed stadiums either do hold or are promoting the inclusion of arena events, their success in terms of spectator satisfaction is less than ideal. If the 200-ft limitation is adhered to, together with a seating height limit above the floor of 65 to 70 ft (the resultant of sight-line angles and code limitations on riser heights), the maximum capacity will prove to be from 20,000 to 22,000.

Plan Configurations

One of the earliest decisions to be made in the design/planning process must be that of the basic physical form of the arena seating plan. The relative merits and problems of four plan forms in Fig. 7 will be discussed:

Straight Rows Ends and Side The straight-row arena is the simplest and most economical of all possible seating configurations. Most early gymnasiums with spectator seating took this shape, many utilizing fold-away bleachers or platforms which are readily adaptable to the straight-row plan. There is also minimum waste of seating area due to the absence of wedge-shaped sections between aisles. The seating sections are of course rectangular between pairs of parallel aisles. The aisle spacing can be set based upon the desired seat width and the maximum seats allowed between aisles, and it will remain constant for all rows. In a small arena tailored around the size of a basketball floor this shape is perfectly satisfactory. However, in a larger multiuse space where the rows would be straight for the length of ice hockey (200 ft or more) spectator viewing problems will begin to develop. As an example, a person sitting in seat X will be required to swing his line of sight laterally from left to right far enough to see both goals on the hockey ice. The view to the right requires a quite extensive movement (approximately 60° from a straight-ahead position). This will not only prove uncomfortable to the viewer (and many seats are worse than X in this regard) but visibility is additionally impaired the further the spectator must look left or right. This will be discussed at a later point dealing with sight lines and referred to as the "picket fence effect."

Straight-Row Sides and Curved-Row Ends This is perhaps the most commonly employed plan for arenas now in use. It maintains the economy and efficiency for a good portion of the seating paralleling the playing floor but takes the end seats around in a circular configuration from a radius point near each end of the floor. If the two radii are located well short of the ends of the hockey ice, thus keeping the straight rows as short as possible, a spectator in seat Y will have been relieved of much of

Recreation and Entertainment
SPORTS ARENAS

Fig. 6 Boxing.

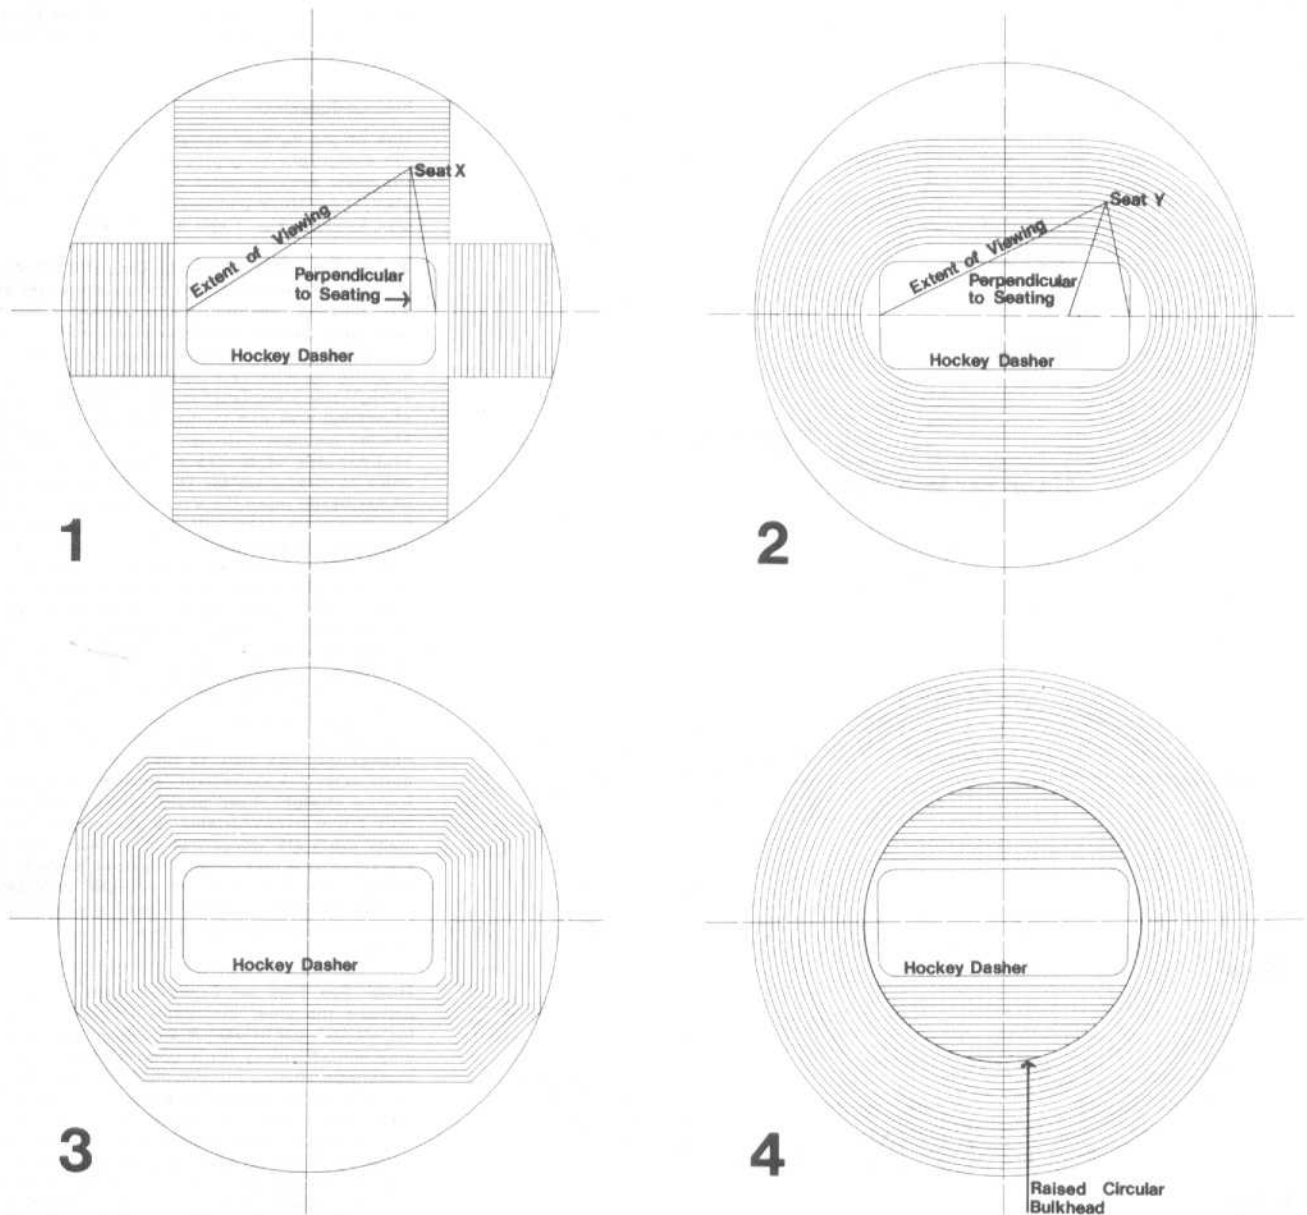

Fig. 7

the discomfort of seat X in Fig. 1. The maximum lateral movement for Y, which is now located in the curved area, is about 45° . Also, the line perpendicular to the seat falls much nearer to the center of the floor or the average center of activity for most events.

Straight Rows, and Sides with Diagonal Corners This plan configuration, also quite common, has all the advantages and disadvantages described in Fig. 1. Only those seats in the diagonal corners have relief from the lateral head-movement problem inherent in the side seats. In terms of construction economy it is the least costly of any configuration with full-perimeter seating, lending itself to precasting or other methods of repetitive trend/riser fabrication.

Circular Seating with Straight Rows at Side Lines Upon quick examination it would appear that a circular plan would be the optimum arena seating configuration. This might be true if all arena events were the size of a boxing ring and

seating could radiate outward and upward from a small central floor area. However, the introduction of an 85×200 ft hockey rink into the scheme brings with it almost irresolvable problems. In order to clear the ends of the hockey rink the innermost full circular row of seats must have a radius of about 110 ft. The height above the floor of this first circular row can be set no greater than 3 to 4 ft if spectators in the end seats are to see the near goal. Thus if this 4 ft height is followed around the row to the center point of the sidelines, a seat at this point will be 58 ft away from the dasher with only 4 ft of elevation. The seats along the sidelines within the space formed by the hockey dasher and the first circular row pose the dilemma. There is space for about 18 straight rows of seats, but with only 4 ft of elevation at the rear row of this group each riser could be only $2\frac{1}{2}$ in. This would be too low for adequate viewing by spectators in otherwise prime seats. If the reverse approach is taken and the height of the first circular row is established at an elevation appropriate for the sideline

seats, the height will be about 10 ft (18 rows at 7 in.).

Following this 10 ft height around to the end of the rink would result in the first row end seats being 10 ft behind and 10 ft above the dasher—much too high for these spectators and those in the rows behind them to see the near goal. About the only possible way to employ this configuration is to omit the sections of straight-row seating along the sidelines and set the circular bulkhead at the low elevation. This has been done in a few arenas, the Palazzo dello Sport in Rome being one, but is not likely to be adopted in a commercial arena due to the large loss of prime revenue-producing seats. There is in addition a loss of intimacy between spectators and the game activity, which is very desirable to maintain, when such a large void exists between them.

Elliptical-Row Seating (Fig. 8) This configuration as illustrated for the Forum in Inglewood, California, and also used at Madison Square Garden in New York City has proved to be an

Fig. 8 The Forum, Inglewood, California.

Recreation and Entertainment

SPORTS ARENAS

optimum plan shape for this type of multiuse arena. It is the best possible adaptation of a curved-row configuration, desirable to minimize lateral head movement to the governing size of an ice hockey rink. In both examples noted above, the outer perimeter of seating was carried to a circular outer wall line. This being done primarily to take advantage of the structural economies of a cable-suspended roof system. The intersection of the elliptical seating form and the circular outer wall generate an undulating line at the perimeter. The high point of this undulation, and thus the maximum number of rows, occurs along the sidelines, and the low point with minimum seating occurs at the ends of the arena. The radius of the outer circular wall was held to approximately 200 ft to stay within the practical limits of spectator visual acuity as discussed earlier. The elliptical seating form was developed from circular arcs on a 4-center point system. Radius points for the two broader sideline curves fall 200 ft above and below the center line for the tighter end curves. They are 61 ft left and right of center.

Madison Square Garden seating differs from the Forum in one respect—the addition of a balcony (Fig. 9). As mentioned above, the main

body of seating has an undulating intersection with the outer wall with a low point at the arena ends. Above these low end seats, space develops which can accommodate balcony seating. Madison Square Garden takes advantage of this option to gain maximum capacity. The balcony is given a circular configuration seven rows deep following the outer wall line. For a portion of the sideline areas the balcony blends with the main body of seating rising from below but is kept separated by a continuous circumferential bulkhead.

Seating and Sight Lines

The study of spectator sight lines in section should proceed simultaneously with development of the arena plan configuration. Sections should be developed at both the arena axis and several intermediate points in any curved plan configuration to verify the arrival point of sight for the maximum number of seats.

The "Picket Fence Effect" It is impractical to provide riser heights sufficient for spectators to see over the heads of persons in the row immediately in front. It is assumed view will be between heads of persons one row in front and

over the heads of those two rows in front. Looking straight ahead, a spectator will have a reasonable wide angle of vision between two heads immediately in front. However, the further one looks to the left or right following players' action on the arena floor, the more this cone of vision between heads diminishes. It is the same effect as one gets standing a few feet in front of a picket fence. Looking straight ahead between pickets the view is little impaired, but as the eye moves left or right, the pickets gradually appear to move together until at some point they appear to form a solid surface. It is for this reason as mentioned in discussing alternate plan configurations that the curved-row plans are preferred over straight-row seating as they minimize the lateral viewing angle and thus the picket fence effect.

Two-Row Vision When plotting graphically or calculating sight-line sections, assume a spectator's seated eye level at 3 ft 11 in. above tread elevation and 5 in. from eye level to top of head. In most arena situations the hockey floor size will be the most restrictive in determining proper sight-line profiles. If sight lines can be made to work for hockey, they will be more than adequate for all other smaller floor size events.

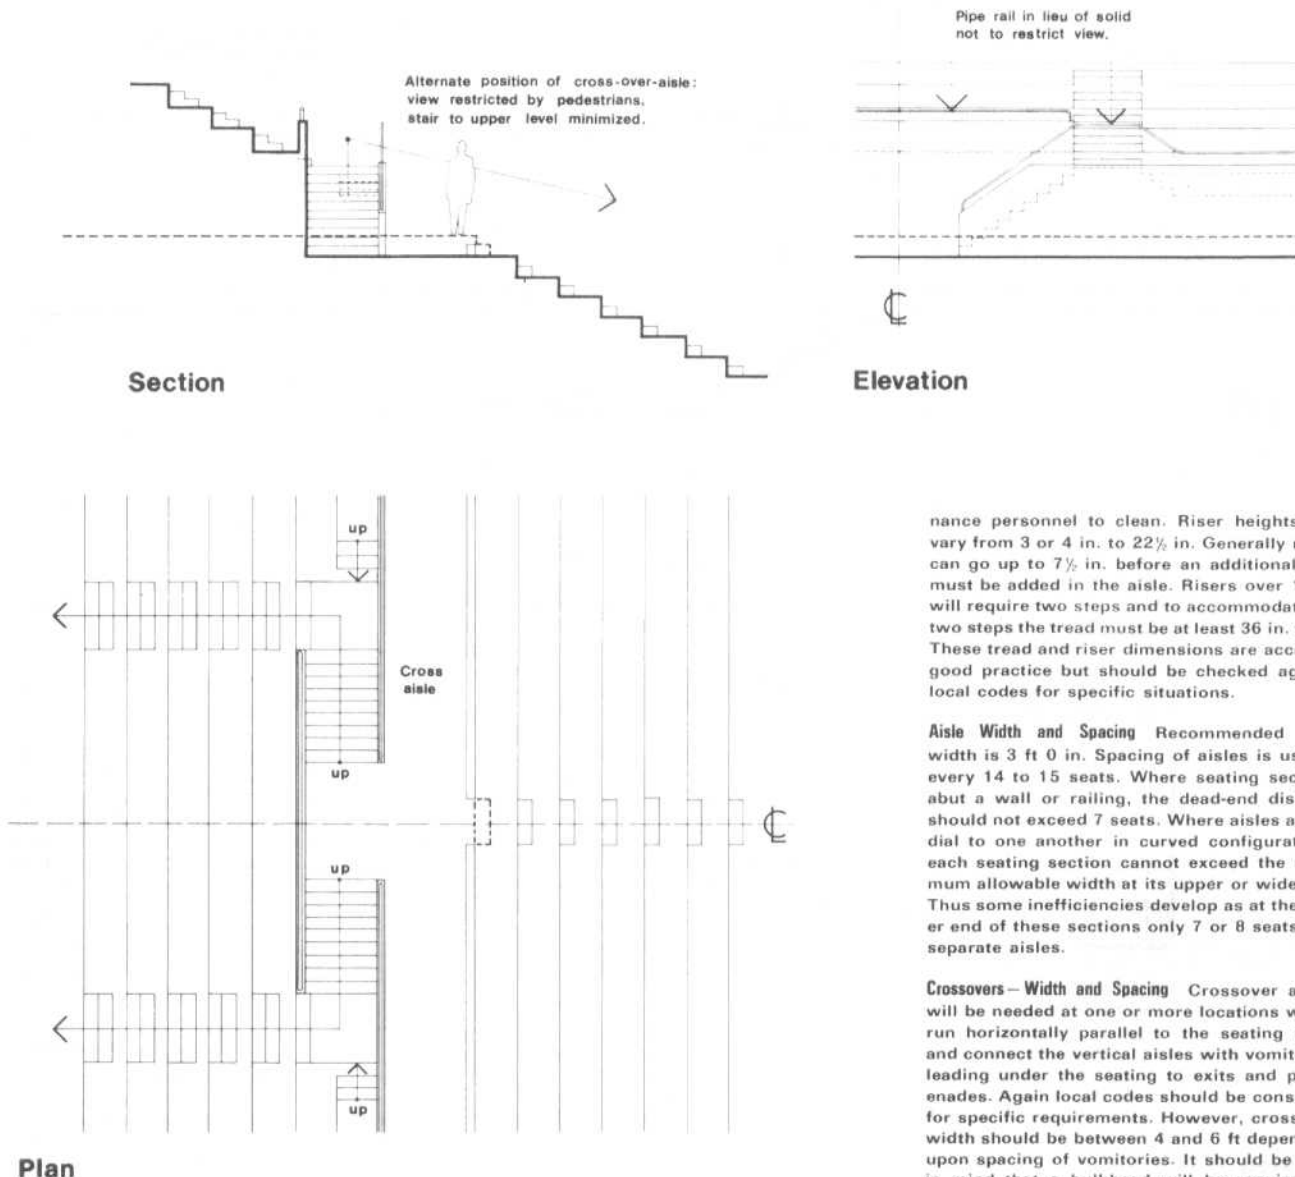

Fig. 9 Balcony.

Plan

Fig. 10 Vomitory—Type A.

The arrival point of sight should be made to fall at the top edge of the near hockey dasher (3 ft 6 in. above floor level). To graphically plot a series of sight lines, begin by assuming a height above the floor for the first row of fixed seats. This should be as low as possible to still accommodate temporary seating which will fall between the playing surface and the first fixed seats. Next extend a line from the arrival point of sight (APS) to the top of head of the first row spectator (tread height + 4 ft 4 in.). If you continue this line up and to the rear the distance of two rows, you will set the eye level for the third row of spectators. The trend height for this row will then be found by subtracting 3 ft 11 in. Tread heights are now established for the first and third rows; the second row will be midpoint between them. This procedure should be repeated for each successive row working from the bottom up. When a full section of seating is plotted in this manner with all sight lines meeting the same APS, the section profile will have a slightly dish or bowl effect, with each riser height being a fraction of an inch greater than the one below. For

the sake of construction economy, risers are grouped in sections of four or five of the same height before an increase is made. Several trials may need to be made to keep the overall profile within desired limits. Changes can be made in the original assumptions of first tread elevation and tread width which can alter the cross section as successive rows are plotted. For instance, if too high an elevation is selected as the lower row starting point, the upper rows may develop riser heights which exceed code limits, or the overall building height might prove too great.

Tread and Riser Dimensions Tread width of rows should vary between 32 and 36 in. The wider dimension is generally used in the lower tiers of seats which are of shallow slope and where the extra comfort is commensurate with their premium cost. Any tread width below 32 in. should be avoided if possible especially if upholstered seats are used. In addition to sacrificing spectator comfort, narrower rows inhibit travel to concessions at intermissions and prove more time-consuming for maintenance

personnel to clean. Riser heights will vary from 3 or 4 in. to 22½ in. Generally risers can go up to 7½ in. before an additional step must be added in the aisle. Risers over 15 in. will require two steps and to accommodate the two steps the tread must be at least 36 in. wide. These tread and riser dimensions are accepted good practice but should be checked against local codes for specific situations.

Aisle Width and Spacing Recommended aisle width is 3 ft 0 in. Spacing of aisles is usually every 14 to 15 seats. Where seating sections abut a wall or railing, the dead-end distance should not exceed 7 seats. Where aisles are radial to one another in curved configurations, each seating section cannot exceed the maximum allowable width at its upper or wide end. Thus some inefficiencies develop as at the lower end of these sections only 7 or 8 seats may separate aisles.

Crossovers—Width and Spacing Crossover aisles will be needed at one or more locations which run horizontally parallel to the seating rows and connect the vertical aisles with vomitories leading under the seating to exits and promenades. Again local codes should be consulted for specific requirements. However, crossover width should be between 4 and 6 ft depending upon spacing of vomitories. It should be kept in mind that a bulkhead will be required at the rear side of the crossover and the tread of the first row behind it raised to a height to allow sight lines not to be interrupted by the lower seats. Where site conditions permit, it is ideal to have both a lobby/promenade and a crossover aisle at or near grade level. The seating can then be split with approximately one-half below grade and one-half above, which very much simplifies exiting problems. Crossovers at the top of balconies should generally serve not more than seven rows of seats. Aisles running up from a crossover and dead-ending at a wall or bulkhead should not serve more than 18 to 20 rows.

Vomitories As stated earlier vomitory width and spacing will be governed by local code conditions. When they are used in connection with horizontal crossovers, stairs will be required to reach the first row to the rear of the crossover which must be elevated 4 to 5 ft. Two types of vomitories are illustrated:

Vomitory Type A (Fig. 10). Here a stair leading to the upper seating flanks either side of the vomitory passage. These stairs are entered at their lower end before reaching the crossover and thus minimize crowd congestion. Two

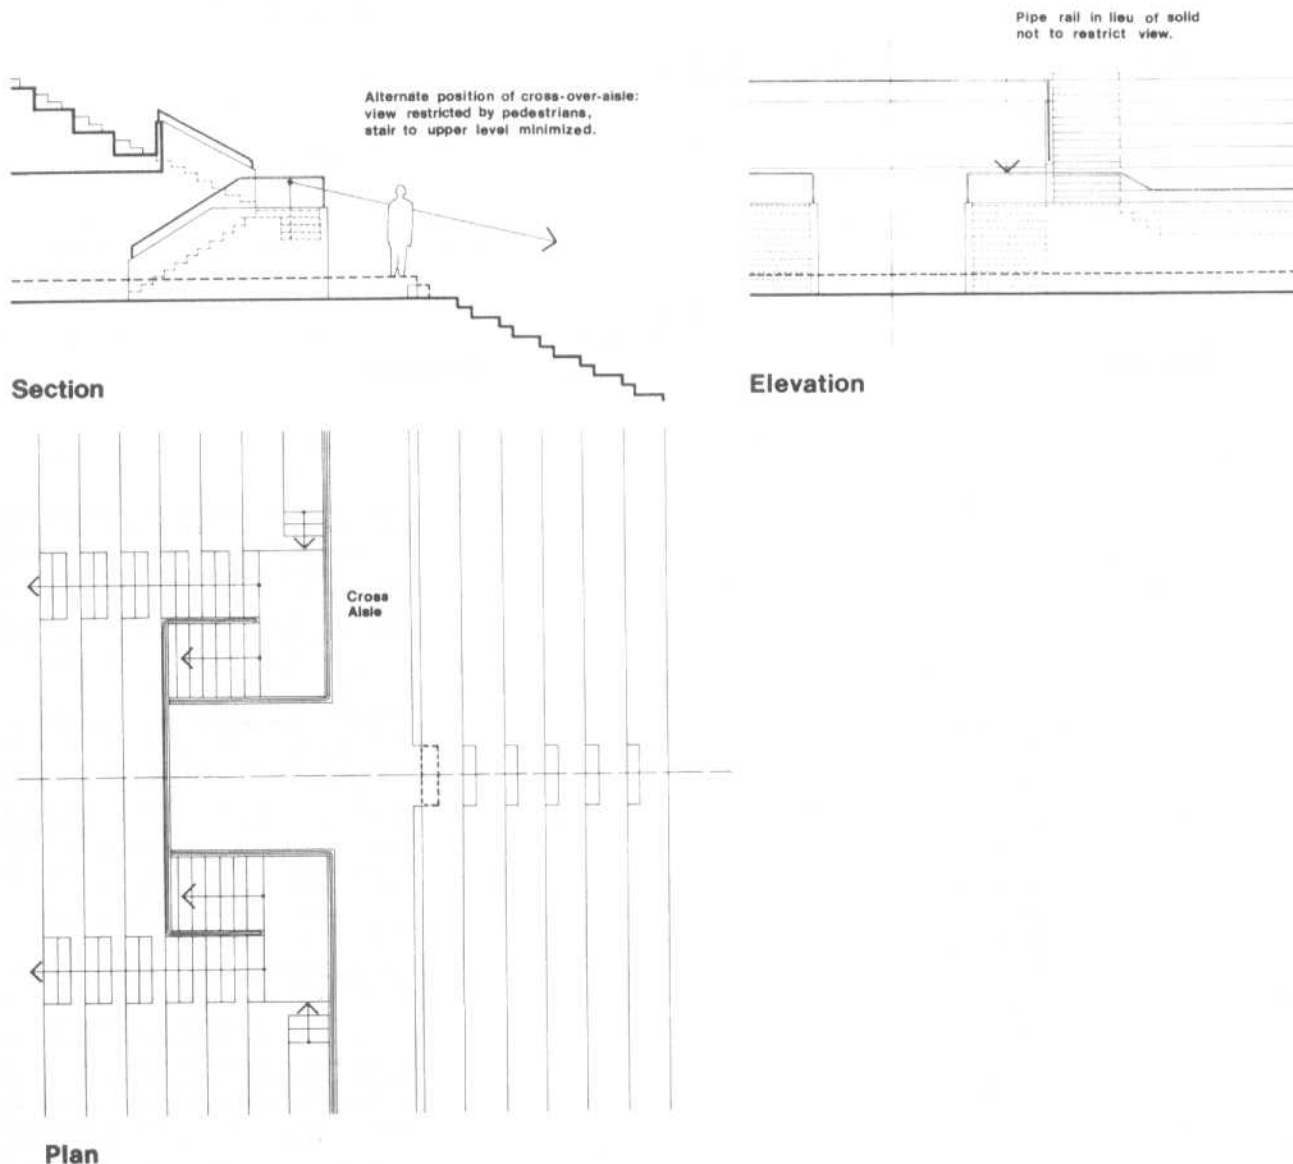

Fig. 11 Vomitory - Type B.

possible elevations exist for the crossover relative to the seating tread levels. It can either be flush with the last row of seats on its front side or be one riser above this last row. The crossover at the lower level minimizes visual interference for spectators in the upper seating from those walking the crossover and is the preferred alternative. The other option does reduce the height of the bulkhead and thus the number of steps required to reach the upper seating. Railings on these stairs and bulkheads should be solid for their lower portions with open pipe rail above. The total height should be kept as low as allowable to prevent sight line interference.

Vomitory Type B (Fig. 11). This detail may be used either as part of a full vomitory or as a stair access only to upper seating tiers. It is not as desirable as Type A in a vomitory situation, as the stairs empty into the traffic path between crossover and vomitory and can cause excessive congestion.

Truck Access. Access to the playing floor surface for large trucks will be required at one or more points. Vomitories at least 10 ft

wide and 14 ft high should be provided at one end of the playing floor. Two are preferred in those arenas expecting to book circus performances to allow for the promenade of animals and performers out one and in the other. Temporary treads and risers can be placed over these large vomitories to gain seating capacity when they are not in use. It also follows from the exterior to this floor level by some means as well as to the loading/receiving area of the building. Additional vomitories will be needed to give spectator access to and from the temporary floor seating setups. Also required will be an opening or vomitory at one end of the arena floor to allow for the overrun for indoor track dash events. At least 20 yards should be available past the finish line of the 60-yard dashes for this purpose.

Temporary Seating For most events some amount of temporary seating must be set up to fill in the gap between the fixed seating and the size of the playing surface or performance area. This will in some cases be flat on the floor or on shallow riser platforms.

To minimize labor cost for setups, the largest amount possible of this seating should be on platforms which telescope out from the periphery of the fixed bulkhead line. Where riser heights are sufficient to permit it, these seats can be left attached to the platforms and folded flat to allow stands to be pushed against the bulkhead wall. Where this is not practical, the seating and/or the platforms will have to be disassembled, stacked, and moved to storage areas in other parts of the building.

Crowd Movement

Great care should be taken in the design/planning process to avoid building in situations which will inhibit the smooth flow of spectators through the public circulation spaces and to and from the seating areas. This should be true for normal traffic situations or avoiding panic in emergencies. Activities which involve spectators waiting in lines must have sufficient room so that circulation is not blocked behind them. Toilet rooms must be laid out so that peak usage at intermissions is handled

as fast as possible to avoid backups within the rooms and the corridors. Shallow pitch ramps should be used wherever possible in lieu of stairs at floor level changes. If escalators are used, ample room must be provided at their landings. Blockages must not occur and force dangerous situations as more spectators are forced into the space as they are delivered by the moving escalator. The general pattern of circulation must be clear, orderly, and easily comprehensible by the spectators. Graphic aids will help as discussed later, but they cannot overcome built-in planning flaws.

Building Codes

Code requirements relating to arena planning will be primarily concerned with exiting and seating circulation. It will be found that where they exist at all, regulations will vary widely from one locality to another. Many codes do not have any references to arenas at all, and interpolations must be made between specifications for theaters and outdoor stadiums. When this is the case, the designer's assumptions should be checked at an early stage with local building officials to avoid changes after final drawings are complete.

SPECTATOR REQUIREMENTS

Seating

Most arenas now being built are employing theater-type upholstered seats. The minimum recommended width is 19 in., and they should vary up to 23 in. center to center for the prime areas. In the wedge-shaped sections in curved rows, a mix of widths is usually used to make the ends of each row come out as flush as possible. Where risers are 5 in. or over, seat stanchions should be riser-mounted to facilitate cleaning. Seats should be self-rising with perforated acoustical treatment on the seat bottoms.

Concessions

Concession stands for food, beverages, souvenirs, and coat checking should be provided at convenient locations in the promenade areas. Counter areas should be as long as practical and if possible recessed in alcoves to prevent backup of patrons into circulation spaces. Storage space should be provided immediately adjacent to each counter area so that food items can be restocked to the sales area during a game or performance without a trip to the central supply point. If it is contemplated by the arena management that an outside concession firm be brought in to run the operation, it should be selected as early as possible and participate in the planning process. If the firm is an experienced national operation, it will have strong points of view on counter locations, size, visibility, and utility requirements among others. If not built into the original building, the concessionaire's desires will likely prevail at a later date and unsightly and costly additions result.

Toilet Rooms

Sets of men's and women's rest rooms should be provided at one or more locations on each public level. Their layout must provide for peak loads during the 15- to 20-minute intermission periods when hundreds of patrons will pass through each room. It is ideal if a one-way traffic flow can be developed with an in and out doorway separated by some distance. With-

in, the space should be divided with the water closets and urinals located near the entrance and the lavatories in a space near the exit. Also it is desirable if possible to design each toilet room so that half of the space can be closed off by some means during events of small attendance. This will save a good deal of operating cost for cleaning. Plumbing-line capacity should be studied carefully for peak use and generous pipe spaces with good access provided.

Graphics

A good graphics and signing control program is important not only for an attractive appearance, but for controlling and expediting crowd movement. Signing can help establish a clear pattern of movement which can easily be comprehended by the patrons. Seat colors in the arena can be keyed to ticket colors to identify the various areas or categories of seating. This can be done on a horizontal basis with rings of seats changing color as they change from one price category to another. Or the arena can be divided into quadrants each with its own color key. In cases where the arena sits within a large parking field, this color system may even extend to the exterior and guide patrons to the proper entrance as they park and approach the building. Within the seating area, signs designating sections, rows, seats, etc., should be large, clear, and located in easily read places. Signs for rest rooms, concessions, telephones, etc., should also be of good size and clear and consistent in style. In the lobby ticketing area, space must be provided for coming attraction signs, current event pricing, and seating plans for various event setups. It has proved successful also to have a scale model of the arena seating including colors and section identification within the ticket sales area to assist patrons with their ticket purchases.

Scoreboard

Two basic types of scoreboards are in common use. The center-hung 4-sided type is one, wall-mounted single-faced the other. The central type is usually on a drop cable system which allows it to be lowered to the floor for maintenance. The central speaker cluster can also be combined with this type scoreboard, but it should be checked early whether the same suspension height is appropriate for both scoreboard visibility and sound distribution. When the wall-mounted type is used, at least two units will be required so that all spectators will have a proper view. Very often the building management will arrange for advertising display to be incorporated into the scoreboard design as a revenue-producing device. If so, the decision should come as early as possible, as it will have obvious effect on size and detailing. The boards, of whichever type, must have provisions for the major sports that are likely to use the arena and have a portable control console that can operate from several positions depending on the sport involved.

Public/Private Clubs

Most new arenas will include a club or restaurant facility. These are often tied to the purchase of season tickets and their use restricted to these patrons. Capacity might vary from 150 to 300 people. This facility should be located within easy reach of the seating area and also be accessible to patrons at hours other than when the building is open to the general public for events. If an outside con-

cessionaire is involved for the arena, it will also likely manage this club. A typical commercial kitchen will probably be required and should be so located as to be easily serviced from the central trucking/receiving area. This kitchen may also serve to cater food to other parts of the building such as the owner's suite and press lounge.

OPERATING REQUIREMENTS

Administrative Offices

Areas for the building manager, accounting, personnel, booking, publicity, and engineer are generally provided within the building. In addition, office space may be required for the various teams who use the building, whether they are only tenants or are owned by the arena owner. Additionally, office space should be available for use by shows booked into the arena for an extended period (circus, ice shows, etc.). Also, the owner of the arena, if it is a private venture, will usually require a suite of rooms including his office, private bath, and a conference/meeting room suitable for entertaining dignitaries. Food may be catered to this area from the central club kitchen; thus it should be within easy access. It is possible in some instances that a portion of the offices mentioned could be located in other space remote from the arena. This decision and a full program of office requirements should be developed at an early stage of the design/planning process.

Ticketing Facilities

This area will vary depending upon the intended scope of events to be booked. However, in most situations, ticket booths will be required in the lobby area or an outer lobby. They should be accessible to the public during non-event periods without losing security to the remainder of the building. Madison Square Garden has 25 booths, the Forum, 20. Immediately to the rear of the booths should be a large ticket room for storage and sorting advance sale tickets. Also required will be a money room with vault, group sales office, ticket manager's office, and a work area for storing event posters and making up ticket pricing boards.

Storage

Large bulk storage areas will be needed for a variety of uses. The temporary seating setups for the arena floor will require space to store both chairs and riser platforms. These are usually stacked on metal pipe racks as high as ceilings will permit and handled with forklift trucks. Space for storing the hockey dasher boards and glass, basketball floor and goals, and indoor track must also be provided. All of these should be so located relative to the arena floor as to minimize time and cost for the setting up of each event.

Locker and Dressing Rooms

If the arena is the permanent home of two professional teams (hockey and basketball, for example), a pair of separate home team dressing rooms will be required (Fig. 12). As illustrated, the teams can share toilets, shower room, a training area, and the trainer's office. The hockey dressing area should be somewhat larger than that for the basketball dressing area because of larger team size and more cumbersome equipment. A pair of rooms for visiting teams somewhat smaller than the rooms for home

SPORTS ARENAS

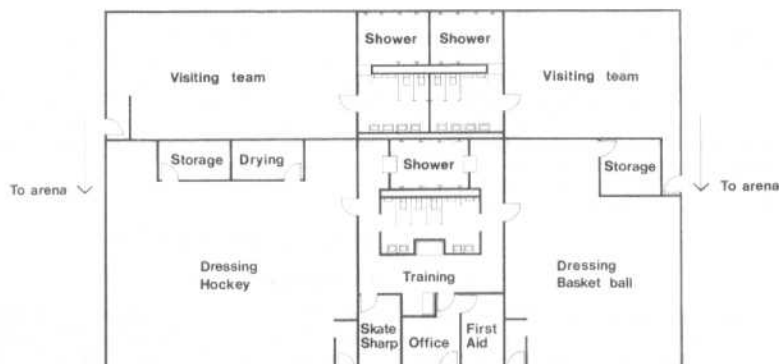

Fig. 12 Dressing rooms.

teams, can be located adjacent to or nearby with home team rooms as shown. Several smaller dressing and interview rooms should be planned in this area. Some can be for individual use, others for four to six people, and each with appropriate toilet facilities. All these spaces should be located at arena floor level with convenient vomitory access to the playing floor. Public exiting traffic should be directed away from the dressing area corridors.

Press Facilities

A press workroom with adjacent Teletype room and toilet should be located near the lower seating area. It is also desirable to include a lounge in this group with facilities to set up a small bar and food service from the main concession kitchen. A small photographer's work area and darkroom should also be provided at the arena floor level. Location of the press seating varies widely. Many arenas which have been built with elaborate press booths high above the floor have discovered them unused, reporters preferring to sit at court-side near the action. Radio and TV announcers, however, usually prefer to sit high for an overall view of the action. Booths for this purpose can be located over vomitory openings or suspended from the ceiling or balcony structure.

Concession/Vendors' Storage

Large bulk storage areas will be required for the concessionaires' supplies of dry food goods, beverages, meat, general supplies, souvenirs and programs. This may include walk-in refrigerator space and cold rooms as specified by

the operator. Also needed will be a concession manager's office, a security area for counting money and a vault. Ample vendors' stations will be needed at several points around the arena. They must be located within easy reach of the seating and be laid out to allow fast refill of the seat vendor's stock. Separated in-out doors are helpful.

Employee Toilets/Lockers

As seen from the following space allocation summary, several categories of employee spaces will be necessary. General cleaning and maintenance help, ushers, and concession employees each need separate toilet/locker facilities. As local conditions might warrant, space may also be needed for security guards and parking lot employees. Definitive space needs for each group will depend upon a management analysis of the numbers of staff required.

Television Broadcasting

Facilities appropriate for the telecasting of events are an important ingredient of all new arenas. Consensus as to number, location, height, and angle of camera positions is hard to find, especially if several networks or local stations are likely to be working out of the building at various times. However, an attempt should be made during the design/planning stage to meet with those broadcasting groups most likely to use the building and build in as much as possible such items as camera platforms and cable runs. Primary use of television in any arena will be for sporting events rather than stage or performance-type shows.

Camera locations for hockey and basketball should all be from the same side of the playing floor with one position high at center ice (at Madison Square Garden it is 64 ft above the floor and 120 ft back from the near dasher) and other positions at low level covering center ice and each goal. Space will also be needed for the station's remote truck, preferably at the building truck area, or a permanent TV monitor room. Any cables from the various camera positions will terminate at this point whether built-in or separately laid for each event. A built-in cable system which can be used by any station's crew is obviously desirable, as it prevents the unsightly view of large bundles of cable as well as avoids interference with circulation at the cross aisles and vomitories.

SPACE ALLOCATIONS

The following space allocations for the Forum in Inglewood, California, an arena of 18,424 seats, can serve as a planning guide and checklist of required facilities:

	Area, sq ft
1. Play floor surface	26,900
2. Lobby promenade	20,000
3. Concession stands	2,500
4. Public toilets	4,800
5. Home team lockers/toilets	4,300
6. Visiting team lockers/toilets	2,100
7. Dressing/interview rooms	1,200
8. Press work area	600
9. Darkroom	150
10. Men employee toilets/lockers	1,200
11. Women employee toilets/lockers	700
12. Men ushers' toilets/lockers	400
13. Women usherettes' toilets/lockers	600
14. Men concession toilets/lockers	350
15. Women concession toilets/lockers	500
16. Truck dock	4,500
17. Receiving area	1,300
18. Storage—bulk	8,800
19. Storage—concessions/vendors	6,000
20. Storage—temporary seating	6,600
21. Storage—dasher glass	250
22. Ice machine	250
23. Administrative offices	9,000
24. Ticketing facilities	7,000
25. Private club dining and kitchen	
26. Pay telephones—22 booths	

PUBLIC GOLF COURSES

Ideally the golf course should be designed and constructed so no major alterations ever will be required. However, even the greatest of golf courses have been revised and the organizers of a new golfing enterprise need not expect that their course will be the one in the world that will not eventually need some changes.

It always is advisable to engage the services of a competent golf course architect. Even if funds do not permit initial construction of the course so it will be completed with all the trapping of a finished course, the qualified architect's plan will provide for later installation of traps as money is available and the course will develop according to a wise plan instead of being a rather expensive and unsatisfactory exhibit of inexpert experiments.

There are many instances, particularly in rural areas, where the budget is limited. Services of a professional golf course architect may seem unnecessary. But knowhow is extremely important in planning and building a course. It is a wise investment to have someone experienced lay out the course, and especially to oversee construction.

Golf architectural authorities remind us that Nature is the best golf architect. The famed courses of Scotland which now are fundamentally as they were almost a century ago are proof that small town golf club organizers can do a great job if they are fortunate in selecting—or having available—sites that fit golf. Natural hazards make the most interesting and easiest and cheapest maintained hazards. The genius of the golf architect often shines brightest in his use of these natural features of terrain in providing shot problems.

But in many instances the ground is flat and without trees. The problem then is to provide a layout that will call for every sort of a shot that the best courses demand and that is usually done, as far as possible, simply by judicious variation in length of holes.

Such tremendous advances have been made in mechanical moving of earth that at even the flattest of sites not much money is required to move enough soil to elevate a green, taking the earth from locations where grassy hollows or areas for sand traps are left as improvements in the design of the course.

Selection of Course Site

The golf architect usually considers a number of prospective sites for a course and selects the one that, at reasonable cost of land, can be converted into a good course at minimum construction cost and maintained properly at minimum expense.

Size of property is important. For a 9-hole course, 50 acres is generally considered the minimum, and 110 acres for 18 holes. Even these areas involve risk of injury of players playing parallel holes. For the better courses,

80 acres for a 9-hole course and 160 for 18 holes is about right. Irregularly shaped plots often afford opportunities for most interesting course design.

Land shouldn't be too rugged. A gently rolling area with some trees is preferable. Land that is too hilly is tiring on players, usually necessitates too many blind shots and is more costly to keep well turfed.

The course should have practice fairway area close to the clubhouse. Some public and daily fee courses have installed practice ranges, lighted for night use, adjoining their courses or alongside the highways, and from these ranges they get considerable income and develop golfers for day play on the courses.

Accessibility

Unless absolutely unavoidable, a golf course should not be off the beaten track. This is especially important in the case of a small-town course planning on having the green fees from transients help to meet maintenance costs. Locate your course along the main highway into town. All other things being equal, design the course so one or two holes parallel the highway; it is good advertising.

Another reason for not locating the course in an out-of-the-way spot is that the club should have good transportation for the members. It should be as near to town as possible, cost of land should be taken into consideration, and the main highway from town to the club should be one that is kept in good condition and is not merely a country lane, unpaved and liable to become impassable with every heavy rain.

Soil Factors

Condition of the soil is extremely important because in the final analysis the better the stand of turf raised on fairways and greens, the more satisfactory and more popular will be the course. The ideal golf course soil is a sandy loam. It is not impossible but is expensive to grow a good stand of grass on a heavy clay. Be sure to take the character of soil into consideration when choosing the site.

Soil analysis of areas of the golf course site will be made at low cost by state agricultural departments or county agents. Considerable helpful information can be supplied by state agricultural experiment stations and county agents in determining the most desirable site from the viewpoint of good turf development and in recommending the grass seed, growing, and maintenance program.

Past Use

Closely tied in with the above is the use to which the land has been put in the past. Is the plot a run-down farm where a large part of the plant food has been removed from the soil, or is it rich in the elements that will be necessary for successful cultivation of turf? Has the land lain idle for many years or has it been intensively cultivated by its farmer owner without his returning plant food to the soil?

The selection of property that has been well kept up as pasture land is highly advisable. Much money is saved in putting the course into excellent condition. Frequently the scenic attractions of a site are such that to the susceptible and uninformed organizers of a golf club, they totally outweigh soil conditions. A happy balance should be maintained between both factors. Pick a site which will offer no serious handicaps to the attempts of the club to grow a stand of grass and maintain it thereafter.

Power and Water Availability

Water and power are absolute necessities for any modern golf course. Even in the smallest communities, grass green courses with a clubhouse are being built. To water only greens and tees, or the whole course, and operate a clubhouse, you must have power and water.

The source of water should be close to the site, reliable and pure enough to drink and irrigate fine turf. It may be a city system, wells, lake, river or some combination. The cost of connecting to water and power supplies must be included in your plans.

How Much Clearing?

Consider next the amount of clearing that will have to be done in building the course. Will it be necessary to move many trees or grub out many stumps? Will it be an expensive proposition removing stones from the soil? Are there large swamp areas that will have to be filled in or drained? Do not misunderstand the statement above relative to clearing out trees. A golf course should, if possible, have patches of woodlands, as trees offer one of the best natural hazards if properly placed with reference to the course. However, it is an expensive matter to remove large growing trees, and the site selected should not have too many of these in those portions of the plot which will be fairways in the final picture.

Natural Golf Features

The last consideration in selecting the site is whether or not it possesses natural golf features.

This may seem to the uninitiated to be the first and most important thing to look for, but, as a matter of fact, natural golf features, while extremely desirable, are not nearly as important as the character of the soil and site location.

Rolling terrain, creek valleys, woodlands, ravines, ponds and the like, of course, make the job of designing an interesting course just so much easier, but all of these features or a substitute for them can be secured through artificial hazards. For this reason the presence or absence of natural golf features is perhaps less important than any of the factors that have been mentioned above.

Clubhouse Location

Location of the clubhouse, entrance drive, parking spaces, tennis courts, swimming pools, golf practice and lesson tees, fairways and traps and practice greens, is another job

Recreation and Entertainment

GOLF COURSES AND CLUBHOUSES

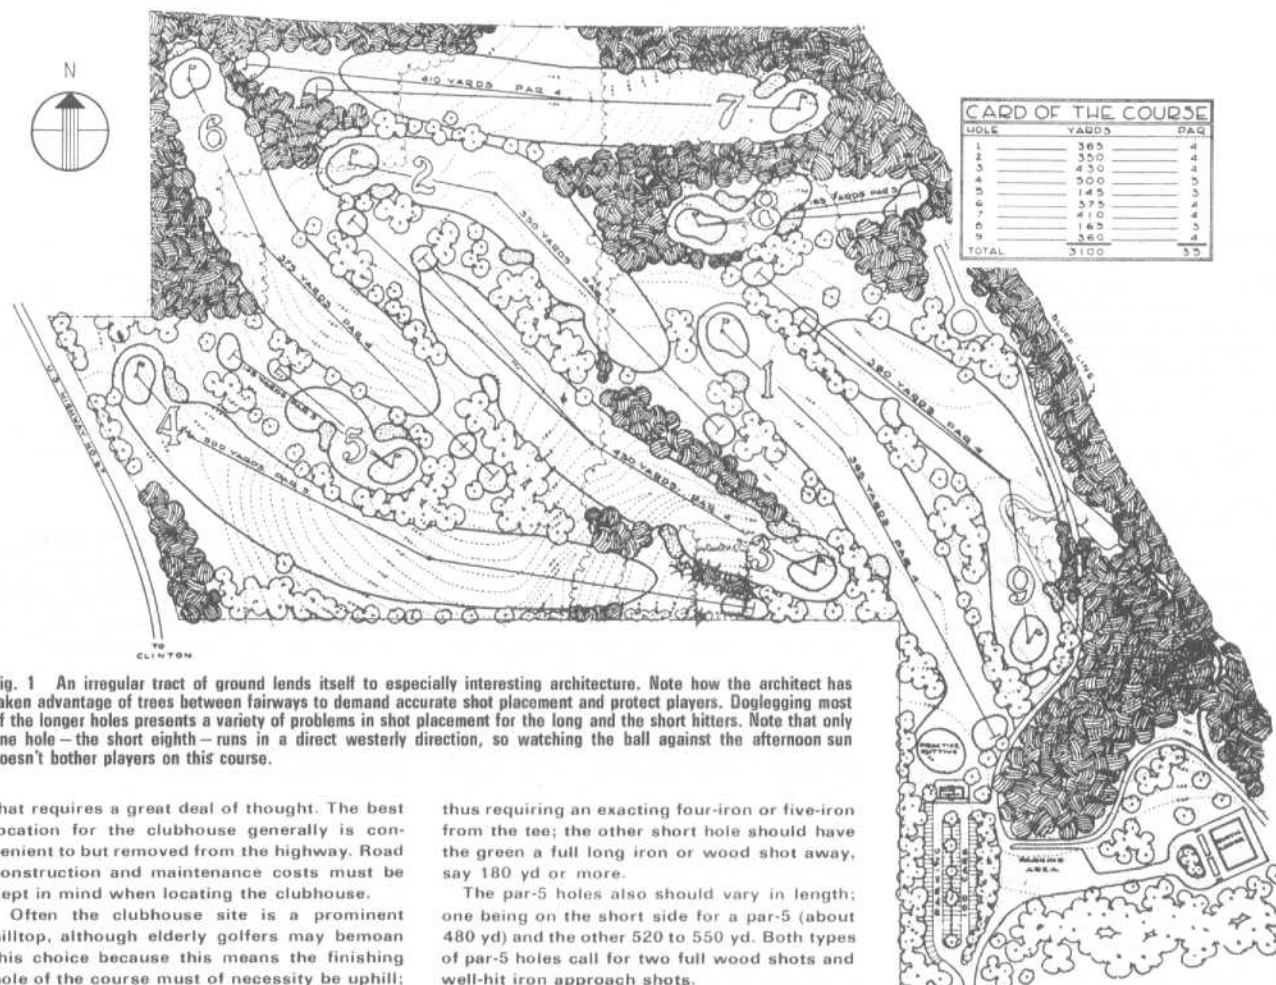

Fig. 1 An irregular tract of ground lends itself to especially interesting architecture. Note how the architect has taken advantage of trees between fairways to demand accurate shot placement and protect players. Doglegging most of the longer holes presents a variety of problems in shot placement for the long and the short hitters. Note that only one hole—the short eighth—runs in a direct westerly direction, so watching the ball against the afternoon sun doesn't bother players on this course.

that requires a great deal of thought. The best location for the clubhouse generally is convenient to but removed from the highway. Road construction and maintenance costs must be kept in mind when locating the clubhouse.

Often the clubhouse site is a prominent hilltop, although elderly golfers may bemoan this choice because this means the finishing hole of the course must of necessity be uphill; they do not like a heavy climb at the end of a strenuous day of golf. Generally, a convenient and practical site can be found at a less elevated spot.

Mapping the Course

Authorities are well agreed on what makes the "ideal" nine-hole course in the matter of distance. All agree that such a course should measure over 3,000 yd, preferably around 3,200 yd. These authorities likewise agree that the par¹ of the course should be 35, 36, or 37, with the first mentioned most general. Just how should these 3,200 yd be apportioned among the nine holes? Most experts suggest two par-3 holes, two par-5 holes, the remaining five holes to be par-4's. Par-6 holes should be avoided. (See Fig. 1.)

Considering first the two par-3 holes, they should vary, for obvious reasons, in length; the shorter one should measure 130 to 160 yd,

thus requiring an exacting four-iron or five-iron from the tee; the other short hole should have the green a full long iron or wood shot away, say 180 yd or more.

The par-5 holes also should vary in length; one being on the short side for a par-5 (about 480 yd) and the other 520 to 550 yd. Both types of par-5 holes call for two full wood shots and well-hit iron approach shots.

It is advisable to provide a mixture of pars, points out architect Robert Bruce Harris. He suggests a par order of 4-5-4-3-4-5-4-3-4—36 as one that will be found highly satisfactory.

Under U.S.G.A. regulations, the minimum length of a par-4 hole is 251 yd, and throughout the country many courses contain holes of this length. Yet, only in rare instances where some physical feature redeems the lack of distance do these holes rate as even of average interest. They are too short; after the drive nothing remains but an easy chip-shot or run-up; there is no "kick" to playing so short a hole.

Indeed, this same objection attaches itself to par-4 holes even as long as 350 yd, where physical peculiarities are lacking.

This distance, from 251 to 350 yd, is known among golf architects as "No Man's Land," a zone to be avoided if the course is to be genuinely popular with golfers.

Now that we have established a minimum length for the shortest of the par-4 holes, how shall we vary the length of the remaining four? It is very simple: They should be graded up by easy stages to the upper limit of par-4 (470 yd) so that after a regulation drive from the tee, the player is called upon to hit approach shots with different clubs.

Course Planning

Certain standard practices should be observed in making a course layout, among which the important ones are:

1. The distance between the green of one hole and the tee of the next should never be

more than 75 yd, and a distance of 20 to 30 yd is recommended. Tees should be not closer than 20 yd to a green because of the danger of being hit by an approaching golf ball.

2. The first tee and the ninth green of the course should be located immediately adjacent to the clubhouse. If it is practical without sacrificing other factors, bring the green of the sixth hole also near to the clubhouse. This is a feature appreciated by the golfer with only an hour to devote to his game, as six holes can be comfortably played in that time and at the finish of his available time he is once more back at the clubhouse.

3. As far as is practical, no holes should be laid out in an east-to-west direction. The reason for this is that a considerable volume of play on any golf course is in the afternoon and a player not only finds it difficult and disagreeable to follow the ball's flight into the setting sun, but it also presents a safety problem to other golfers. If an east-west hole is unavoidable, locate it among the first two or three holes of the layout so that a player will strike it as early in his round as possible. Southwest direction of holes is particularly bad.

4. The first hole of the course should be a relatively easy par-4 hole of no more than 380 to 400 yd in length. It should be comparatively free of hazards or heavy rough where a ball might be lost, and should have no features that will delay the player. This is for the obvious reason of getting the golfers started off on their game as expeditiously as possible.

¹Par is an arbitrary measure of the difficulty of a hole. It is the number of strokes an "expert golfer" would take to play the hole, always allowing him two putts after his ball is on the green. A par-3 hole, therefore, is one the "expert golfer" can reach from the tee in one shot; a par-4 hole, in two shots; a par-5, in three shots. Par figures for men and women, as established by the United States Golf Association, are as follows:

Men: Par-3, holes up to 250 yd, inclusive; par-4, 251 to 470 yds., incl.; par 5, 471 yd and over.

Women: Par-3, holes up to 210 yd, inclusive; par-4, 211 to 400 yd, incl.; par-5, 401 to 575 yd; par-6, 576 yd and over.

Recreation and Entertainment

GOLF COURSES AND CLUBHOUSES

5. Generally speaking, the holes should grow increasingly difficult to play as the round proceeds. It takes a golfer about three holes to get well warmed up, and asking him to execute difficult shots while he is still "cold" is not a demand that he will appreciate.

6. Whenever practical, greens should be plainly visible, and the location of sand traps and other hazards obviously apparent from the approach area, which is that portion of the fairway extending teeward for approximately 125 yd from the green.

7. Generally speaking, fairways sloping directly up or down a hillside are bad for several reasons: (a) steep sloping fairways make the playing of the shot by the majority of players a matter of luck rather than skill; (b) the up-and-down climb is fatiguing to the golfer; (c) turf is difficult to maintain on such an area.

8. If there are ravines or abrupt creek valleys on the property, a splendid short golf hole could consist of a tee located on one edge of the ravine with the green on the other, a suitable number of yards down or up the ravine. This calls for perfect control in carrying the ravine, permits the golfer to "bite off" as much of the ravine as he thinks he can carry, and does not unduly penalize the beginner, who can play straight across the ravine and then progress greenward on the other side.

9. The par-3 holes should be arranged so that the first of the two is not earlier in the round than the third hole and the other one is not later than the eighth hole. Par-3 holes should not be consecutive.

The old days of golf courses that punished the shortcomings of the club so severely that

fun was taken from the round have passed into extinction. Along with this penal design are going unnatural looking knobby bunkers, geometrically designed traps and tiny, miserably conditioned tees. Trees, slopes, creeks, lakes and other natural details will provide hazards enough for the average well-designed small-town course. If sand traps around the greens can be well maintained, their use provides the course with a feature that is of metropolitan course character. But if the construction or maintenance cost rules out such traps, turfed hollows in which the grass is allowed to grow several inches high and of a design that fits in the natural surroundings will do well (Fig. 2).

An eminent American golf architect sets forth points that are generally agreed on by members of the American Society of Golf Course Architects. He says:

The backbone holes of the modern golf course are the two-shotters, of 400 yards or over. The length of the two-shot hole offers plenty of opportunity to develop good strategy. Unfortunately, these holes are a little long for the average golfer to be able to reach in two, but this can be remedied by having sets of alternate tees.

The short holes should be kept under 200 yards in length so that every golfer has an opportunity to reach the green with a good shot and thereby obtain his par or birdie. These holes should be attractive and tantalizing in appearance with the greens designed so that they will become extremely formidable or relatively easy depending upon the position of the pin and the angle of the tee in use.

There should be as little walking as pos-

sible between greens and tees, but under certain circumstances it is more expedient to break this rule than to adhere to it. For often, where the property is rugged in type, a longer walk between the green and the tee makes it possible to obtain a good golf hole rather than a poor one.

The holes should be so different in length, character, and architectural type, that there is no feeling of duplication.

The three types of golf architecture—penal, strategic and heroic—should be used in good proportion.

In penal type construction, the traps guard the greens in bottleneck or island fashion. Here the average golfer must either hit the shot accurately or choose a club to play short in order to avoid the trouble which he would ordinarily find at his normal range. One or two holes of this type are usually sufficient in the composition of an 18-hole golf course, and should be the "short" or "drive-and-pitch" holes.

The strategic type utilizes fewer traps, adroitly placed, so that any golfer can hit with his full power but must place his shots to obtain the most favorable results. The modern golf courses are designed with about 50 per cent of the holes strategic in type. This architecture adapts itself best to holes of 400 yards or over, the par-4 holes.

The heroic is a blend of strategic and penal design. The traps or natural hazards, such as creeks, rivers, and lakes, are placed on the diagonal so that the player can bite off as much as he feels he can chew. The more he is able to carry, the more advantageous will he find his position for the next shot. This type of architecture is adaptable to all length holes, and should be utilized on 30 to 50 per cent of the holes of the course.

There should be no blind shots for ap-

Fig. 2 In this nine-hole layout the architect has provided for shot variety by having two tees for each hole. Note too, the practice driving fairway, an important and popular course feature that many clubs have overlooked in their original planning.

Recreation and Entertainment

GOLF COURSES AND CLUBHOUSES

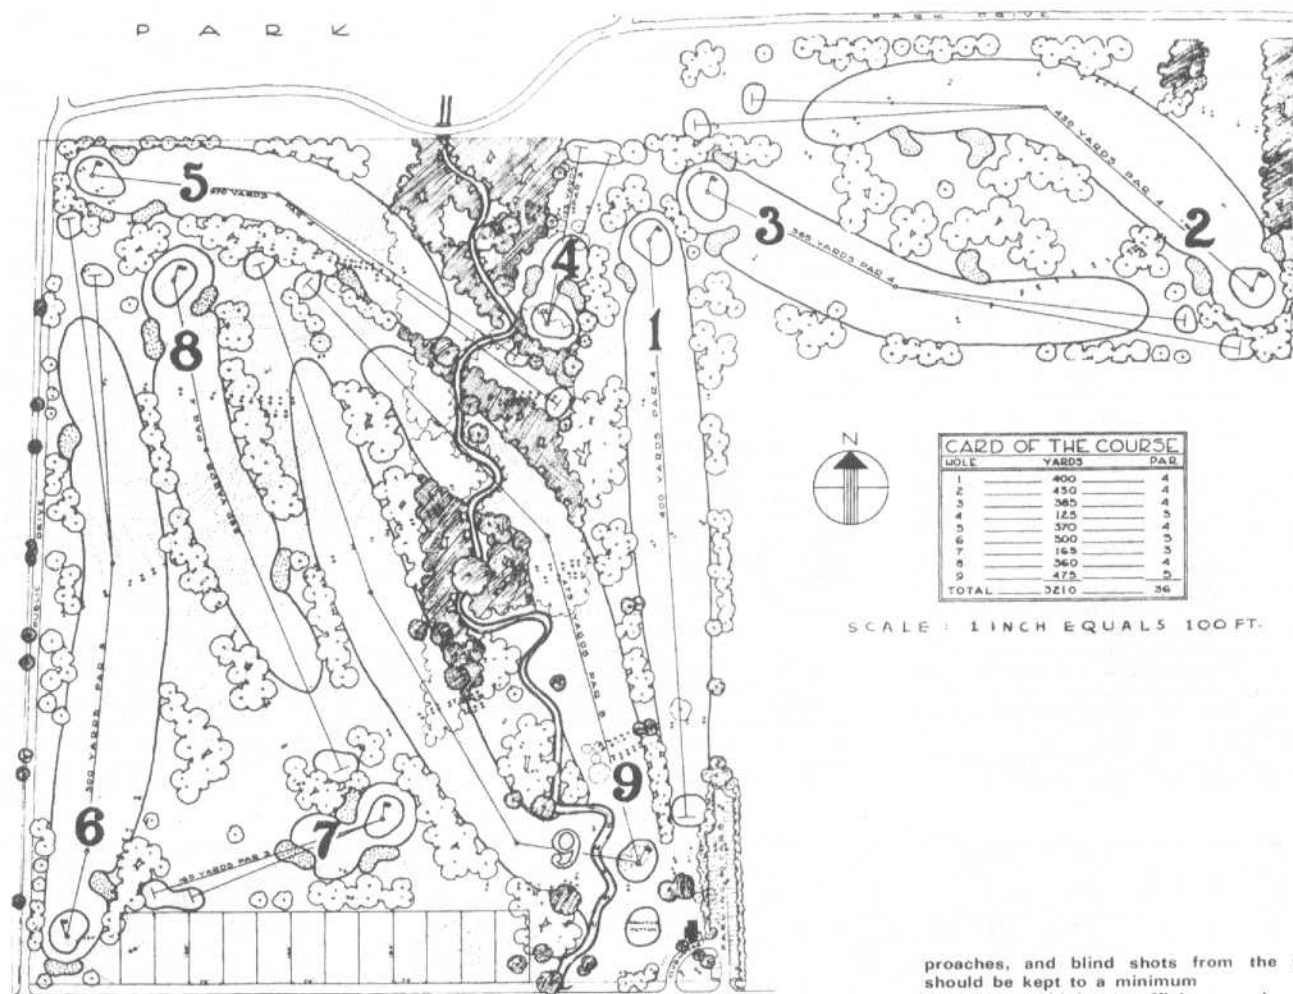

Fig. 3 Double tees add greatly to the variety with little expense. This plan suggests interesting use of two tees on all holes except the first and eighth, to give unusual variety to a nine-hole course. The ninth hole allows the choice of two distinctively different layouts. This sort of arrangement calls for planning that usually is beyond the capacity of any but the experienced golf architect. The 12 rectangular areas at the bottom border of the plan are prospective homesites that make especially desirable residential property when the adjacent golf hole is so laid out that golfers won't be coming into a yard for out-of-bounds balls.

Fig. 4 Typical grading plan.

proaches, and blind shots from the tee should be kept to a minimum.

There should be a sufficient number of heroic carries from the tee, but the routing should be so arranged that the player, with the loss of a stroke, should always have an alternate route to the green.

The character of the course should be so designed that during one round every club in the bag should be used.

No stereotype design can be used, but the principles of the design have to be applied in accordance with the natural terrain and the location of the proposed green.

On level or flat land a nine-hole course of 3100-3400 yards can be laid out in approximately 50 acres but it will be cramped. An 18-hole course of 6200-6500 yards or more would require at least 110 acres. This is a minimum, making the routing of the course extremely tight. Gently rolling land requires approximately 60 acres for 9 holes and 120 acres for 18. Hilly or rugged land will require considerably more because of the waste land where the contours are severe; at least 70 acres will be needed for 9 holes and 140-180 acres for 18 holes.

Before starting the routing of the course all the natural green and tee sites on the property should be examined, and as many of these as possible incorporated in the routing of the course. Natural sites should not be passed over in routing the course in order to obtain a hole of predetermined length, unless the hole would fall within the undesirable length of 250 to 350 yards.

The minimum length for a standard 18-hole golf course is 6,200 yards. A good average is 6,500 yards, and championship length is 6,700 yards and up. The short holes should range from 130-200 yards (par-3) and there

Fig. 5 Typical drainage plan.

are generally four of these holes, but there may be five. Par-4 holes should range from 350 to 470 yards, and there are generally ten of these. Par-5 holes should range from 471 to 550 yards and there are generally four of these.

The length of the hole will be determined by the slope of the terrain and the direction of play, the natural features from tee to green and at the green site, and the desire to obtain a variety of lengths throughout the 18 holes.

Fairway width generally is about 60 yards, but will vary depending upon the type of players expected to play the course, and the strategy of the play of the hole. A yardstick of fairway widths is as follows: 75-120 yards from the tee the fairway will be 40 yards wide; 120-180 yards from the tee the width will be 50 yards; 180-220 yards from the tee the width will be 60-70 yards.

The fairways can then narrow again if desired to the next landing area if the hole is long; that is in the area from 330-440 yards.

The green sizes will vary from 5,000 to 8,000 feet depending upon the length of the hole and the length of the shot called for. The shape of the green will depend upon the strategy of the design, the location and size of the traps, and the length of the shot playing to it.

Where the slope of a green is from front to back, the slope should not be more than five per cent, unless there is a break in the slope by a depression. If the depression is not too deep, the slopes of the depression can go from 10 to 15 per cent.

The slopes on the approach of a plateaued green can run as high as 20 per cent.

Mounds and slopes running from the surface of the green to the sides or back can run up to 20 per cent.

The slopes of the traps in front or on the sides playing toward the green will run from 30 to 40 per cent.

At the entrance of the traps the slopes should not be over 25 per cent so that the golfer's backswing can be taken with a full, clean stroke.

Golf Course Costs

There are four factors which determine more than anything else the wide range which one gets when trying to gather from all sources how much a golf course should cost. These are (1) the cost of land; (2) the natural assets and liabilities of the land chosen; (3) the labor and equipment costs in the area; and (4) the type of design. (See Figs. 3 to 5.)

Practice Area

In laying out the golf course it is well to have an area some 250 to 300 yds long, conveniently adjacent to the clubhouse where golfers can practice their golf shots.

Practice Putting Greens

If at all possible, there should be a practice putting green of considerable area near the clubhouse. This green should be surfaced with the same turf as the greens on the course, should be gently undulating, and is best arranged with nine or eighteen putting cups spotted about the green and numbered so that a player can putt from cup to cup in regular order.

Tennis Courts

Tennis courts get a good play at most country clubs. An area of at least 120 by 50 ft should be reserved for tennis, or larger space if survey of tennis possibilities among users of the club indicates greater need of space.

Children's Playground

Whether a club decides to operate strictly as a golfing proposition or to include the social aspects of country club life, it is a good idea to plan on a children's playground somewhere near the clubhouse.

By HAROLD J. CLIFFER, AIA

PRIVATE CLUBHOUSES

In private clubhouses functions break down as follows: social, golf and other sports, food service, storage, clerical and administrative offices, maintenance facilities, and on-site member, management and employee quarters. The individual components of these functions will vary from club to club, depending upon the size and class of operation involved. Components marked with an asterisk indicate those which are not absolutely necessary to a minimum operation.

Social Functions

In the organization of clubhouse functions the social activities are normally accommodated in the following main and supplementary areas:

Main areas:
Lounge
Cocktail lounge
Main dining room and ballroom
*Private dining and party rooms
*Card rooms

Supplementary areas:
Entry
Vestibule or lobby
Men's and women's toilets and women's powder room
*Porches and terraces
Storage
Checkroom

Lounge

The club lounge is really the stopping-off place for persons or groups waiting to participate in other activities as well as a passive recreation area. It is seldom occupied for long periods and should not be designed to provide seating for large groups gathering for affairs. As a matter of club economics, the space should be relatively small, not too amply furnished and accessible to the cocktail lounge. This acts as an inducement for people not able to find seating in the lounge to gather in the cocktail lounge and have a before-dinner or before-luncheon cocktail. Activity in the cocktail lounge is much more profitable from the standpoint of the management than having the lounge furniture warmed by nonpatronizing members or guests.

In addition to giving access to the cocktail lounge, the lounge should provide entrance to the dining rooms, men's and women's toilets and powder room, coat room and front desk, as well as to connecting circulation to locker rooms.

If there is a demand among the club members for provision of passive recreational activities, a library, museum, trophy room, card rooms, etc., may be provided off the lounge proper.

There has been some tendency in newer clubs to combine the lounge with the dining room. This has the unfortunate result of making the lounge into a dining room most of the time, and in creating the problem of constantly shifting furniture or in the accretion of lounge space by the dining operation, thereby reducing or eliminating the effectiveness of such a space. These spaces may well be contiguous, but some permanent full or partial division should be made between them to preserve the status of the lounge.

The provision of a fireplace in the lounge usually generates the feeling of what has been termed "a more homelike atmosphere." Whether a television set should be included in the lounge is a matter of club discretion. If a certain amount of quiet recreation is to take place in the lounge, then it would certainly be better for the television set to be placed elsewhere, preferably in the cocktail lounge or TV room, where it is an attraction and not a distraction.

Bars and Cocktail Lounge

The bar and cocktail lounge are almost consistently the profit makers for the club. The main cocktail lounge should be provided in the social end of the building. A secondary and smaller bar should be located in connection with the "Nineteenth Hole" and/or the mixed foursome's grill. Portable bars should be avail-

GOLF COURSES AND CLUBHOUSES

able for large parties and receptions as the occasion warrants. As mentioned before, the main cocktail lounge should be accessible directly from the main lounge for those who wish to enjoy a before-luncheon or before-dinner cocktail. There have been some attempts made to place the bar at one end of the dining room, but this has proven unsuccessful on two counts: the drinkers feel too inhibited about imbibing freely while exposed to the scrutiny of the diners, and as a result of too little patronage, the management has complained bitterly that the bar cannot make money in such a location. Costly remodeling has been occasioned as a result of the incorrect placement of bar facilities and the lack of recognition of the traditional habits of even the most casual drinker.

Dining Rooms

The main dining room should be designed to take care of the day to day service of the membership as well as the special functions of a more regular nature. This is where the information obtained from the membership survey or from the management will come in handy in determining the scope of the dining area. Once the type and degree of patronage of the dining functions have been determined or estimated, then space can be allocated to handle the traffic. The type of menu and turnover per table are customarily used in arriving at proper space allocations for commercial operations. About 14 sq ft per seat is generally accepted as adequate in planning dining rooms for clubs.

If a dance floor is to be provided, estimates as to proper size for this function should reflect the frequency and intensity of use for a typical operating year. Normally, the dance floor may be used to accommodate tables for regular dining. However, dining space must be adequate to handle seating for those occasions on which the dance floor must remain free; otherwise a furniture moving problem is created which is both costly to the club and inconvenient to the members and guests.

In addition to a main dining room for the day to day service of members, additional private dining rooms should be provided for the private parties which are or will become a part of the club's standard operations. Most club managers at clubs with over 300 members agree that an absolute minimum of two such private dining rooms are necessary, one to handle about 20 to 25 people, and one to handle groups of about 60 to 70 people. Where two or more private dining rooms are provided, a pattern of flexibility should be considered such as using folding doors to make the spaces as adaptable as possible to a wide variation in the size of groups.

Private dining rooms should be private in the truest sense of the word. To have them open onto other dining or gathering places in any way can be a source of irritation and embarrassment to a host, who may have invited certain friends from among the membership and not others, and to the guests who have to face their uninvited friends as well. To provide privacy for the club members during outside parties or business luncheons taking place in private dining rooms, these rooms should be accessible from the lounge or the main entrance.

All dining rooms should be closely grouped around the food preparation center for the maximum speed and efficiency of service. Circulation to and from the kitchen in no case should be across public spaces. Circulation to private dining rooms should, insofar as pos-

sible, be directly from the kitchen and not through other dining spaces.

Dining porches and terraces, like other dining facilities, should be convenient to the kitchen. A dining space in or near the kitchen area should be provided for the dining room and kitchen help.

Supplementary Functions

Ordinarily, very little needs to be said about the supplementary functions of entries and vestibules, toilets, storage and check rooms. Yet, a surprising number of newer clubhouses have overlooked these features either in whole or in part. One northern club with a new clubhouse neglected to provide a vestibule to shield its members from the biting cold of the northern climate. Another club in the midwest forgot completely to include a coat checkroom. And, if any problem is common in the field of clubhouse design, it is the failure to provide adequate storage facilities. This applies to storage in all areas of the club and is discussed in more detail in a following section.

Clubhouse entrances, particularly in clubhouses located in climates which experience moderate to severe winters, should be designed with double sets of doors so that occupants of the areas immediately adjacent to the entrance are not subjected to cold blasts of air. In addition to providing more comfort, this arrangement also cuts down on heat losses and reduces fuel bills.

Provision should be made near the building entrance for a checkroom large enough to permit the storage of such items of outer apparel as are usual in the club's local climate. In addition, the checkroom should be large enough to hold a number of garments consistent with the size of the membership. Referring back to the programming in the previous section, the size of the checkroom and number of garments held should bear a direct relationship to anticipated or known patronage.

Occasionally, it is possible to make the toilet facilities of the golf section of the clubhouse available also to the lounge, dining rooms and cocktail lounge. However, it is considered better practice to keep these separate in order to be able to close off the locker room during social affairs.

The number of fixtures required in the toilet rooms normally will be dictated by local codes and ordinances. Generally accepted standards for the number of fixtures in the social end of the building are as follows:

Number of persons served	Number of water closets
75 to 100	5
101 to 125	6
126 to 150	7
151 to 175	8
More than 175	Add 1 water closet for each 30 additional persons

Where the number of men and women members is known, fixtures should be apportioned accordingly. In men's toilet rooms, 66 percent of the water closets may be replaced by urinals. Lavatories should be supplied at the rate of one for every four water closets and/or urinals. A women's powder room in connection with toilet facilities is generally provided, although it is not absolutely necessary.

Golfing and Athletic Functions

The following are the main and supplementary areas normally provided with golf and pool facilities:

Main areas:

- Men's locker room, showers and toilets
- Women's locker room, showers and toilets
- Pro shop
- Sales and display area
- Office
- Club and cart storage
- Club cleaning room
- Stock room
- Attendant's station—
- shoe cleaning, clothes drying and pressing
- "Nineteenth Hole" or men's bar and grill
- Mixed foursome's grill
- Pool locker, shower and toilet facilities (boys and girls)
- Caddie house and caddie yard

Supplementary areas:

- Entrance and vestibule from parking area
- *Steam room and masseur's room
- *Quiet rooms
- *Auxiliary card room
- *Electric car garage

Golf Facilities

With a little imagination, the golf facilities section of the clubhouse can be made considerably more attractive than they have been in the past. To say these accommodations often have been treated as an afterthought in clubhouse design would be an understatement. Locker rooms have been placed in dark, poorly ventilated basements, with exposed piping and ductwork overhead.

Clubhouse Circulation

The natural division of social and athletic activities in club operation is the key to clubhouse circulation patterns. One entrance should be provided to the social activities of the clubhouse, and one entrance should be provided to the athletic activities of the clubhouse from the parking area.

Within the clubhouse, circulation from the social activities entrance should proceed in the following manner from entrance to vestibule to lobby to lounge or cocktail lounge; from lounge or cocktail lounge to main dining room or private dining rooms; toilets and powder room handy to lounge, dining rooms and cocktail lounge; front office desk at lobby, offices behind; coat room at lobby; kitchen centrally located for most efficient service to all dining areas; connecting circulation to golf facilities.

Golfers should, first of all, have a separate entrance to the building and to their facilities so as not to interfere with more formal functions of the social activities end of the building. This entrance should be directly off the parking area. From the entrance, both men and women golfers should have access to their respective locker rooms. From the locker rooms, the golfers should be able to proceed to the pro shop either directly or via a corridor to check with the pro on the schedule of play, the status of foursomes, to pick up balls, tees, score cards, pencils, or some other special item of information or equipment which is needed. From the golf shop the golfer should be able to proceed directly to the first tee. From the ninth green the golfer should be able to reach the pro shop or locker room or toilets without a long hike. And, of course, the trip back to the clubhouse from the eighteenth green

*Not necessary to a minimum operation.

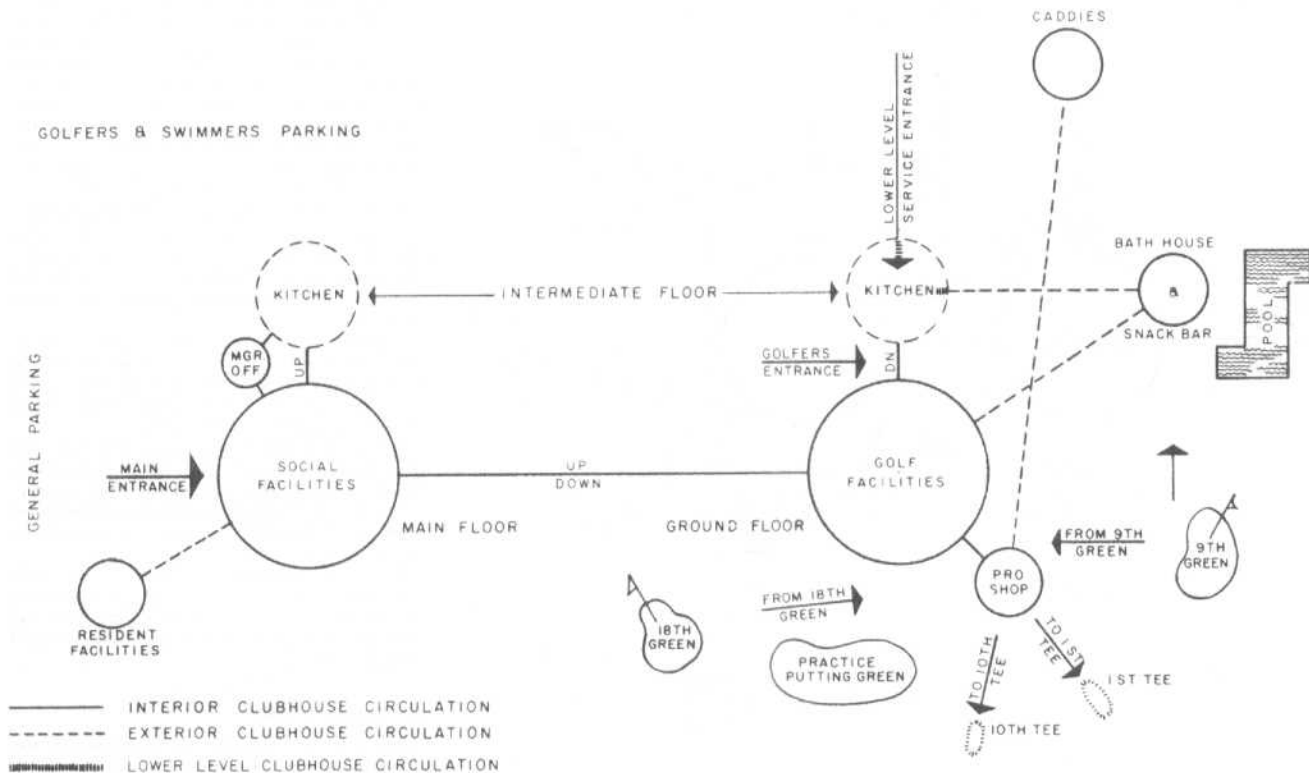

Fig. 6 Two-floor scheme with intermediate-floor kitchen facilities.

should be as short and as easily negotiated as possible for the tired golfer. On the return trip to the clubhouse from the course, the "Nineteenth Hole," men's grill or mixed foursome's grill should be immediately accessible to the thirsty or hungry golfer. Circulation should be provided between the locker rooms and the social end of the house.

Access to teen-age facilities should be directly from the parking area without passage through the clubhouse proper.

Shown in Figs. 6 and 7, in diagrammatic form, are three basic types of clubhouse schemes. They are intended to show functional organization only. Topography, space and budgetary limitations will dictate which scheme is the most feasible in any given case. There may be times when a combination of these types is indicated. From these diagrams, the close correlation necessary between the course and site design and the building design should be apparent.

PUBLIC CLUBHOUSES

Clubhouse buildings for the municipal golf course or the privately owned public fee course are so different in operation and accommodations from the clubhouse for private clubs that they really constitute almost a separate building type. While it is true that many public course clubhouses serve as the focal point for the operation of a local golf club, it is rare that the accommodations of these structures approach the scope and quality of those of the private club.

Comparison of Private and Public Course Clubhouses

Where the private club attempts to make provision for every conceivable social and athletic need its members can afford, the

public course owner or operator, whether a municipality or a private individual, has only one objective in mind: to provide adequate and accessible golf facilities for as many persons as possible at popular prices. This means that all frills and extra services are reduced to a minimum, consistent with a profitable operation. In short, golf is a business and a means of livelihood to the private owner of a public course and a combination business and public recreation service for the municipality, where the private club is usually a cooperatively owned and subsidized social and recreational facility for the exclusive use of the owner-members. In the case of the public course, maximum turnover of play is of utmost importance from the standpoint of service to the clientele and profit to the owner, while at the private club, controlled play on the course is the objective, to assure the members available playing time without waiting or reservations. Moreover, social activities at the public course are primarily limited to socializing on the course and at the snack bar and generally little if any attempt is made, except under the rare and astute management of an occasional private entrepreneur, to provide social activities or dining facilities on or near a country-club level.

Another difference between the municipal and the privately owned public course operation is in the nature of the management. Of necessity the municipal operation must rest totally upon hired personnel or concessionaires, whereas the privately owned operation rests in the hands of the owner and his family and perhaps a minimum number of hired personnel. Fundamentally, this difference has no important implications in the design of these facilities, since it should be the objective of both types of operation to design and construct buildings which can be staffed with as few persons as possible.

Profits from public course operation are derived largely from green fees. However, most public course operators recognize the revenue producing possibilities of a snack bar, cocktail bar and golf shop. If properly designed and attended, these auxiliary operations can and do produce consistently good returns. The question facing most municipal and individual course owners is: what facilities should be provided, how big should they be and how should they be related?

Methods and Criteria for Planning the Public Course Clubhouse

Basically, the public course operator must proceed in much the same fashion as the private club to arrive at the proper size and type of building to suit his needs. The number of factors to consider are fewer but no less complex to analyze than in the case of the private club. Preliminary planning must be thorough, design must be attractive and efficient and construction must be economical.

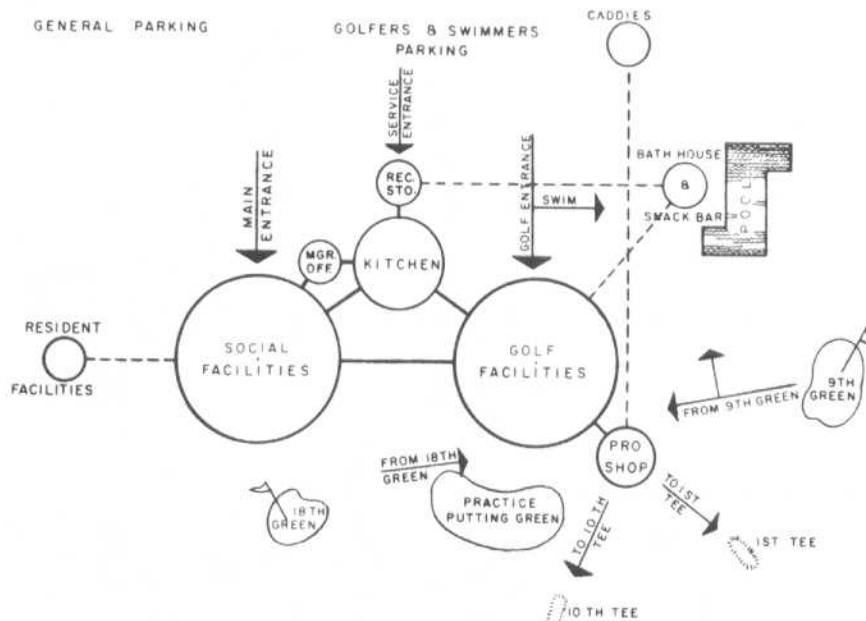

Elements of Clubhouse Design

In a municipal course clubhouse, the essential elements of the design are the starter's booth, golf shop, food concession, lounge and public toilets. Locker and shower rooms may be incorporated into the design, although they are not necessary in all instances, and their use will depend upon local conditions. At privately owned public courses, the owner, in seeking to capitalize on his food operation, may actually increase the proportions of this accommodation to the extent that he has separate kitchen and dining facilities as well as a liquor bar or cocktail lounge.

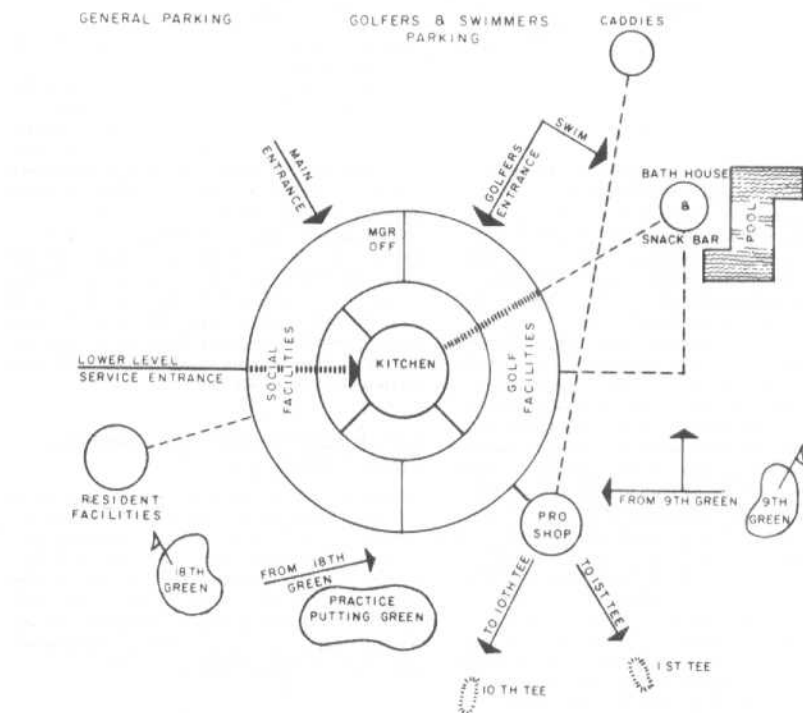

In privately owned operations, where the owner decides to go into an extensive food

Recreation and Entertainment

GOLF COURSES AND CLUBHOUSES

(a)

(b)

Fig. 7 One-floor scheme with (a) grade-level service entrance and (b) lower-level service entrance.

service operation, it is advisable for him, as suggested for private clubs, to call on the services of competent food service consultants as well as an architect. Before anticipating a large scale food service operation, however, the private operator would do well to assure himself that he is well acquainted with the intricacies and pitfalls of food service, or that he can obtain the service of competent personnel, concessionaire or catering service.

One of the prime considerations in the design of public clubhouse facilities is that the functions be arranged in such a way as to allow for the multi-use of employees, or so that the owner himself may attend to several operations at once.

Thus it should be possible for the starter to pinch hit in other operations, such as selling merchandise or food in slack periods. Or it should be possible for the golf professional to double as starter on slow days.

Building maintenance is handled in a number of ways in municipal operations, but the most usual manner is that city maintenance personnel handle it. The private operator, on the other hand, either has to do it himself or hire personnel to do it for him.

The more compact the facilities, the less overhead. As a general principle, the building should be designed so that as little labor as possible is required to operate and maintain the premises.

Clubhouse Functions

In the case of the public course clubhouse, the functions break down in a manner similar to those of the private clubhouse, namely into golf and social functions, in which the social function is reduced to the simple elements of a snack bar and lounge. The golf functions are mainly the golf shop, starter's room and, in some cases, locker and shower rooms.

Normally, the public course golfer will arrive at the course dressed to play with the possible exception of his shoes, which generally will be changed in his car. The question which often confronts municipalities constructing golf facilities is whether to provide shower, locker and lounge facilities, and if so, to what degree and in what manner they should be related to other activities. To establish what has been common practice along these lines, a study was conducted in which 38 communities throughout the country came up with some of the answers.

Clubhouse Relation to Other Recreational Facilities

Very often, to combine all municipal recreation facilities in one central location, municipalities will integrate the golf operation with other recreational activities.

Site Selection

Whether or not a new indoor range is to be located in an existing building or in a newly constructed one depends greatly on the legal considerations of zoning and special use permits.

Anyone planning to build an indoor range should first consult his local government for details of zoning, building codes, and special use permits. Some types of zoning will categorically exclude ranges of any kind; others will allow ranges, but require annually renewable special use permits and/or inspections by the local police or other governmental agencies. Some zoning codes will permit a recreational facility in many different zoning categories. If the proposed range is to be operated on a nonprofit basis by a civic club, fraternal order, or a group of citizens organized for that purpose, the recreational status of the facility may permit a wider range of site selections.

Once the questions or problems in zoning and permits have been resolved, the local building code should be consulted with regard to fire hazards, noise control, insurance liability, health hazards, restroom facilities, etc. This should complete the builder's responsibilities to the local authorities.

Next, the physical site selection should be considered in light of (1) accessibility—is it accessible in all weather conditions? (2) Is parking adequate? (3) Can the range be made physically secure so that there can be no unauthorized use? (4) Are water, sewerage, and electricity available? If not, what costs are involved in obtaining them?

When all of the site selection criteria are met, consideration may then be given to the decision to use an existing building or to construct a new one within the allowable geographical area.

Use of Existing Building

The use of an existing building is usually the most economical way to develop a new indoor range.

A number of factors need to be considered. First and foremost among these is space. The room in which the range is to be built should be at least 75 ft long for a 50-ft range. This allows approximately 8 ft (minimum) each for the bullet stop and firing line, plus a 9-ft assembly and spectator area. Emphasis is placed on the fact that the above dimensions are minimum. (See Figs. 1 to 3.)

The width of a proposed range can vary depending on how many firing points are desired. Normal points for pistol are 4 ft wide; for rifle, 6 ft. Rifle points 5 ft wide may be used if space is limited. Since most indoor ranges are used for both rifle and pistol, 6 ft should be allowed if possible.

Once it is established that there is enough space to locate the range in the existing building, the following factors must be considered:

1. Structural strength—can the floor or framework of the building support the weight of the backstop? A backstop of $\frac{1}{2}$ -in. steel approximately 10 by 25 ft will weigh over 2 tons.

2. Doors and windows downrange must be permanently shut and covered with bulletproof material.

3. The walls, floors, and ceiling must either be bulletproof or be made so. This must also be a part of the structural strength survey—since adding material adds weight. A building which is built of cinder block or brick may be considered to have bulletproof walls for all practical indoor calibers. These are normally .22; .38; and .45 calibers. Wooden buildings should have wall protection of at least 2 in. of plywood. Wooden floors should be protected in the same manner, as should ceilings.

4. An air exhaust system must be supplied, and must be capable of a complete air change from 20 to 40 times per hour. The exhaust fan should be placed above the target line, with the supply to the rear of the firing line, so that combustion gases, lead dust, and other air pollutants are exhausted safely from the range area. If funds are available, a second exhaust duct should be placed just in front of the firing line so that the by-products of firing are exhausted immediately. In some states or local jurisdictions, an air filter on the exhaust may be required so that the contaminants are not exhausted into the open air.

Construction of New Range Building

A new range building may be put up as a shell, and extras added as more money becomes available, or it may be put up as a complete recreational facility. For instance, it would be entirely possible to include an indoor range as a part of a bowling alley complex which could have a restaurant and other recreational facilities.

However, regardless of the approach taken, the new building must meet all building code, zoning, and special use permit requirements as would the conversion of an existing building. In either case, it is strongly recommended that a registered architect be retained to draw up the plans.

DESIGN OF THE ACTUAL SHOOTING AREA

Once a suitable building has been converted to range use, or built specifically for that purpose, primary consideration must be given to the installation of a suitable backstop.

Since the backstop is probably the largest single expense other than the building itself, it is worth spending some time in making the decision as to which type should be purchased.

There are three basic configurations of backstops which are considered to be safe. They are:

1. 45° plate with either water or sand pit

2. 45° reverse plate with dry lead catcher

3. "Venetian blind" type backstops

According to the NRA Shooting Facilities Survey, the most common type of backstop is the 45° plate with a sand pit. It is also normally the least expensive to install, although maintenance may run slightly higher than for other types.

The bullet pit should cover the entire area under the backstop, and should be a minimum of 4 in. deep. The pit should be mined of accumulated lead deposits on a regular basis. The cleaning schedule depends on the amount of use, but would probably average about one mining and sifting operation per month. The sand itself should be changed about once a year, because of the unsatisfactory lead dust which accumulates in the sand.

The inconvenience of cleaning a sand pit may lead to the consideration of a water pit. This requires a water supply and a drain, but makes cleaning the pit an easier task. The water pit has other advantages as it creates no dust, and thereby reduces any health hazard. The lead retrieved is much cleaner than that from a sand pit, and is therefore easier to use for reloading. Lead dust which falls into the water trap is easily flushed down the drain.

Backsplat occurs when a bullet strikes a hard surface. In the case where the surface is smooth, as a good backstop should be, relatively little backsplat is redirected toward the firing line, and it travels only about 15 to 20 ft in small particles. Where the surface of the backstop is rough or pockmarked, the amount of backsplat is increased greatly, and large particles can travel 25 yd or more with enough force to cause injury. This is reason enough to keep bullet traps clean, whether they use sand, water, or are of a patented variety. It should be emphasized that backsplat is a physical phenomenon which occurs when any bullet hits any surface, and is of a much more serious nature if the bullets are made of a hard alloy than if they are of a pure lead.

Backstop Steel Specification

The type of steel which should be used for plate backstops has been a matter of discussion for many years. Different types of steel have been mentioned in reports and manuals, and it is entirely likely that most clubs have no idea what type of steel is in their present backstop.

The previous NRA recommendation for the type of steel to be used in backstops has been SAE 1020. This is too general a specification, as it deals only with the chemical content of the steel in question. In most forms it is too soft to withstand the constant impact of bullets for a long period of time.

Since this specification was inadequate, a study was undertaken to try to determine what type of steel would be satisfactory, and what type of processing treatment would be both economically feasible and have a greater durability than any type of SAE 1020.

It was found that there is a suitable steel which, when processed properly, is of greater

Recreation and Entertainment

RIFLE AND PISTOL RANGES

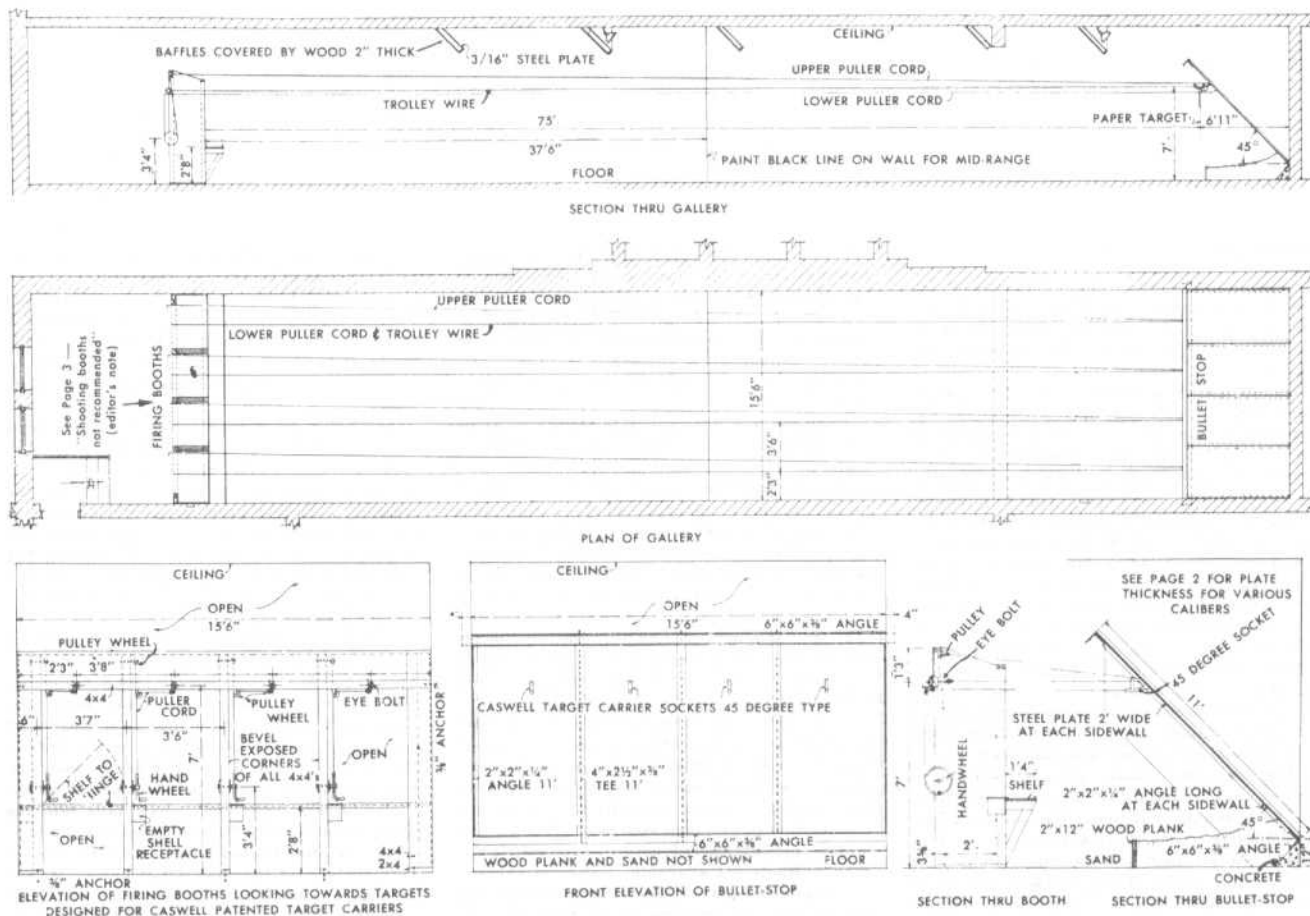

Fig. 1 Fifty-foot indoor range with club room facilities. As shown: 10 firing points each 4 ft wide. Width of building is variable depending on size of club and number of firing points. Structural details should be determined by a local architect or engineer.

durability than SAE 1020. It costs approximately twice as much, but has a much greater life expectancy.

U.S. Steel and Bethlehem Steel both have a specification which is available from warehouse stock. Other suppliers should be able to cross-reference this with little difficulty.

The U.S. Steel specification is type T1-A and the Bethlehem Steel is RQC-100-A.

These are characterized by the following specifications:

- ASTM type—A514, Grade B
- Yield strength, minimum—100,000 psi
- Tensile strength, minimum—115,000 to 135,000 psi
- Elongation in 2 in., minimum—16 to 18 percent
- Reduction of area, minimum—35 to 40 percent
- Brinnell hardness—321

This type of steel, since it is heat treated, requires low hydrogen welding practice in order to avoid impairing the performance of the material in the heat affected zone. Low heat inputs are also necessary. Further information on how to weld this material may be obtained from either U.S. Steel or Bethlehem Steel.

The General Services Administration has written a specification for target backstop

steel in their bulletin PBS: 3-1395 (INT), and the above specified steels come closest to meeting that specification in steels that are easily available in warehouse stock. The bulletin also carries the following specification for construction standards of a 45° plate backstop:

Steel plates supported by concrete or masonry should be anchored by expansion bolts or toggle bolts, as suitable for the construction, with flush countersunk heads, not more than 12 inches on center at all edges of each plate. Joints and edge lines shall be backed with a continuous 1/8 inch plate not less than 4 inches wide. Bolts shall pierce both facing and back plate. Expansion bolts shall penetrate concrete not less than 2 inches.

Steel plates shall have milled edges at all joints. Joints shall be butted flush and smooth. Plates shall be free from buckle or wave after erection. Exposed edges shall be beveled at 45 degrees to a fillet approximately 1/8 inch thick. There shall be no horizontal joints in any steel plate work. Welding shall be in accordance with the American Welding Society Code for Welding in Building Construction.

Steel plate jointed at and supported on structural steel supports shall be spot welded to steel supports not more than 6 inches on center.

The 45° plate backstop should be at least 1/4 in. thick for standard velocity .22 caliber firing only. For .38 caliber wadcutters only, a minimum of 3/8 in. thickness is suggested; and for .45 caliber pistol, including hardball, 1/2 in. is recommended as the minimum. It is recommended that the above minimum figures be exceeded wherever possible. Greater thicknesses are recommended for larger calibers, not because thinner steel is penetrable by them but because the greater impact flows the steel and pocks it more easily. This requires resurfacing more often, and a 1/4-in. plate, for example, would soon need replacement.

In order to avoid the unsightliness of an exposed backstop and pit, some ranges have a "curtain wall" installed. A curtain wall is simply a studded partition with 3/4-in. plywood on the outer face, which in turn may be faced with acoustic tile. Removable sections are built in the wall in front of each firing point so that cleaning the pit is facilitated. A curtain wall provides a dual advantage other than neatness and the ability to use the range as a multipurpose recreation room. It stops virtually all backscatter (which occurs from any backstop of any type), and it helps to keep dust confined to that area behind the wall.

The "venetian blind" type backstop is commercially available from several companies, and has the advantage of taking up about 40

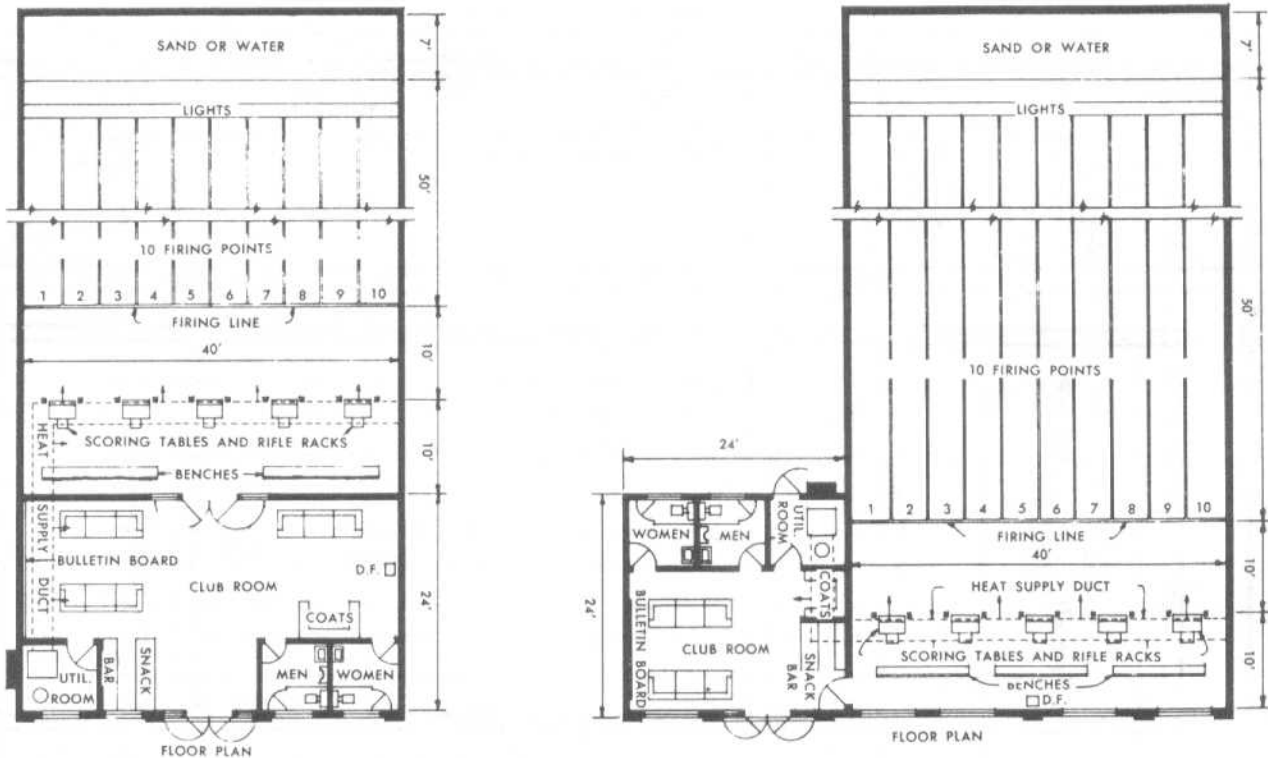

Fig. 2 Indoor rifle range.

percent of the floor space required by any of the 45° plate types. It is more expensive, however, and *should not* be installed by anyone other than the manufacturer. The reason for this is that an *improperly* installed venetian blind type backstop can be dangerous as a generator of ricochets and backscatter. The steel plates *must* be set at precise angles and the top lip of each ground off to a knife edge so that it does not generate ricochets. (See Fig. 4.)

The so-called "reverse 45° plate" backstops are also commercially available, and because of their unconventional methods of catching bullets should also be installed only by the manufacturer.

The safety of all backstops mentioned is equal if they are properly maintained.

Shooting Booths Not Recommended

The NRA does not recommend the use of shooting booths for the following reasons:

They create sections of the range which are concealed from the range officer. Without visual contact with each shooter, the range officer does not have control. Without control, accident potential increases.

They may create a careless mental attitude toward the handling of firearms because they separate the individuals using the range from one another, creating the mental attitude of being relieved of the responsibility to handle firearms in a safe manner.

Booths can also increase the noise level to the individual shooter even if properly constructed because the muzzle blast tends to be reflected directly back at the shooter.

In addition, booths dilute the feeling of being in real shoulder to shoulder competition, which is an important part of tournament shooting.

A Safe Range Interior

A safe range should have walls, ceiling, and floor that are either impenetrable to the bullets of the firearms being used within it, or have internal baffling built so that the bullets cannot hit the walls or ceiling. Since the guns being fired normally on an indoor range are .22; .38; and .45 caliber, it follows that walls which are impenetrable to these calibers are adequate. If guns of higher power are to be used, additional precautions must be taken accordingly. It is not recommended that high-power rifles be fired at a conventional 45° steel backstop because of the probability of penetration rather than deflection.

Masonry walls of any type are usually safe in this case, even with the possibility of .44 magnum pistols being used. This type of wall should be relatively smooth and free of pilasters or other protrusions. If pilasters, etc., do exist, it is recommended that the surface of the wall be covered by ½-in. plywood, at least in the area where the protrusions occur. The plywood should be laid on over standard furring strips so that in case the plywood is struck, the bullet is not likely to ricochet back out. The space behind the plywood acts as a bullet trap into which the bullet tumbles. If the plywood is flush against a wall, a bullet is more likely to ricochet back out.

Wooden or plaster type walls on an indoor range should also be smooth and free of protrusions. They should be covered completely with at least 2 in. of plywood, attached in the same manner as described for a masonry wall.

The nominal 2 in. of plywood can be two 1-in. thicknesses, or preferably three ¾-in. thicknesses of plywood. The plywood will stop any of the standard .22, .38, or .45 caliber bullets which would normally be used. If a heavier caliber is to be used, tests should

be made to determine the protection needed.

Floors which are over another room should be covered with at least 2 in. of plywood as described above for at least 8 ft in front of the firing line, and by at least 1 in. from there to the backstop, providing that .45 caliber ACP is the most powerful cartridge used in the range.

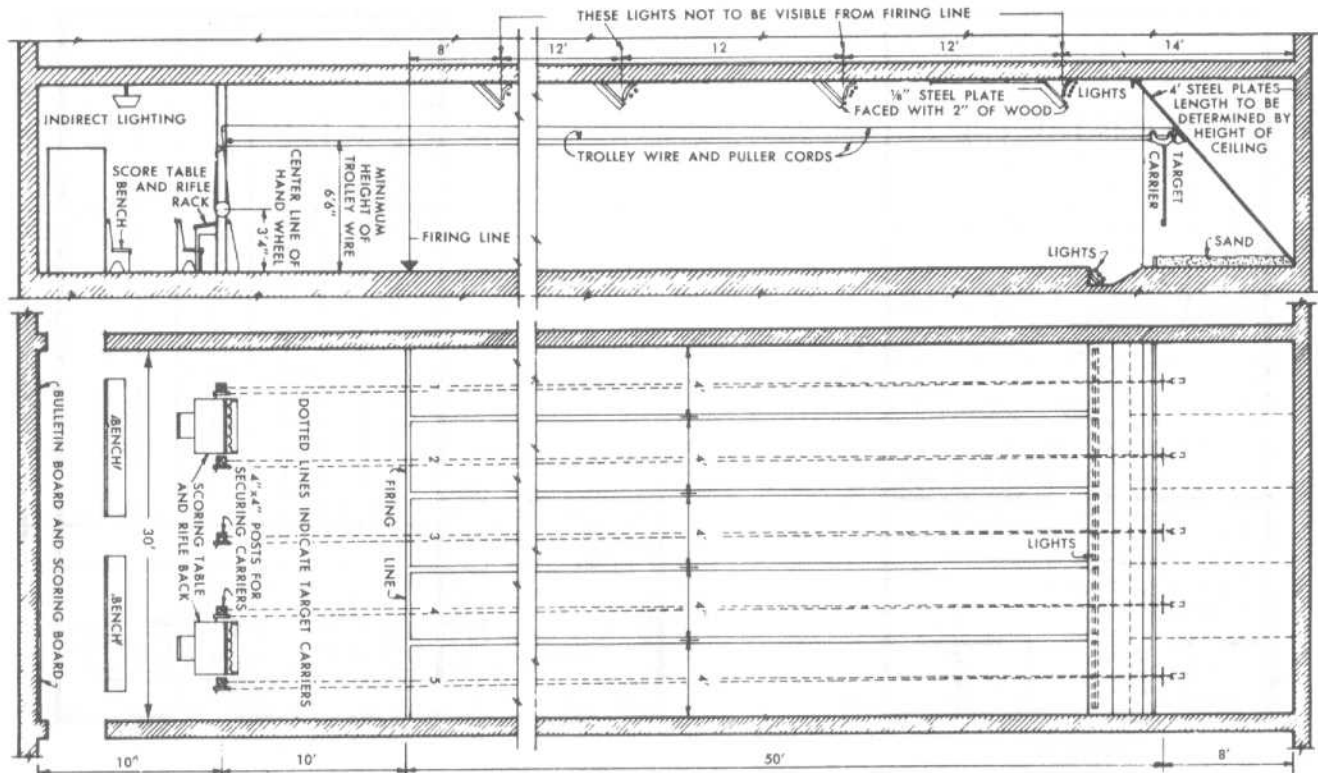

Ceilings present somewhat more of a problem. Since some buildings are constructed using precast concrete, others with steel bar joists for roof or floor supports and still others with wooden beams, measures must be taken to eliminate any possibility of ricochet or penetration. This can be accomplished by the same thickness of plywood as noted above, and at the same distance from the firing line.

Another and perhaps better way in which a high ceiling may be protected is by the use of plywood baffles, arranged vertically from the ceiling in such a way that the ceiling is not visible from the floor level of the firing line. They should not be more than 4 ft in depth. Baffles constructed in this manner will use considerably less material than covering the ceiling entirely, and have the capability of being used simultaneously as mounting for range lighting. They will also act as sound baffles, and if treated with acoustic insulating material as described later in this text, will be very effective in helping to lower the noise level within the range. (See Fig. 5.)

Any service equipment that is exposed down-range of the firing line should be protected. This may include electric wiring, lighting, water pipes, heating and ventilation ducts and exhaust fans. All of these items should be protected by two thicknesses of ¾-in. plywood backed by 12-gauge (0.1-in.) steel.

Flat metal surfaces parallel with the firing line should not exist. If such a surface exists, it should be covered with plywood as described above.

RIFLE AND PISTOL RANGES

GENERAL NOTES: Walls at ends of bullet-stop should be protected from bullet splatter by 1/4" steel plates. Doors between firing line and bullet-stop must be bolted on range side. Arrange lights to have 40 to 50 foot-candles of reflected light from the face of the targets and 5 to 10 foot-candles of indirect light at firing line. Indoor reflector flood lights furnish good light on targets if fluorescent types are not used. Paint walls, ceiling and bullet-

stop a light tint of blue or green. Desirable target carriers may be purchased or made by the club "handy men". If space permits, mount target carriers behind firing line on steel pipes or 4" x 4" wood posts running from floor to ceiling. Provide for drinking water and toilet facilities as well as for heating and ventilation of range areas.

Fig. 3 A revolver gallery for the Minneapolis police department. (Caswell Target Carriers, Anoka, Minn.)

Range Lighting

Range lighting can be accomplished by use of either incandescent or fluorescent sources. The fluorescent type is more expensive to install, but is far more economical to operate and maintain.

Fluorescent lighting is in wide general use, although it can induce eyestrain somewhat more quickly than incandescent lighting because of the higher ultraviolet emission. Whichever type is used, it should be of the indirect or diffused type.

The intensity of the lighting should be rather high (approximately 75 footcandles), and there should be little difference in the intensity level throughout the range area. Under no circumstances should the firing line be dark or dimly lit. This can cause eyestrain. A dark firing line causes an enlargement of the pupil which results in a drop of visual acuity and a corresponding enlargement of the blur circle on the target. The lower edge of overhead lighting protective baffles should be high enough so that a shooter has no problem seeing down-range. Ideally, this would be no lower than 8 ft, so that there is as little "shut-in" feeling as possible.

Range Painting

Painting of the range should be done in light pastel tints with latex flat paint. Bland, pleasing colors such as beige or blue-greens should be selected.

Range Ventilation

One of the major hazards to health in an indoor range is the lack of proper ventilation. This condition exists on a number of ranges which are otherwise well designed.

Air should always be exhausted away (down-range) from the firing line. The preferred spot for a single line of exhaust ducts is over the target line, so that the lead dust generated by bullets striking the backstop is taken out of the area as quickly as possible. If possible, a second line of exhaust ducts should be placed no more than 8 ft in front of the firing line, so that the combustion gases of firing can be taken away quickly.

The combustion of smokeless powder forms carbon monoxide, carbon dioxide, nitrogen oxides, methane, and some solid organic material. All of these products are irritants and in enough concentration can make shooting unpleasant. In a poorly ventilated range, prolonged exposure can cause headaches and nausea, and can irritate eyes and respiratory passages. The major hazard of poor ventilation is the lead dust caused by the lead bullets striking the backstop. The maximum allowable concentration of lead acceptable for an 8-hour daily exposure should not exceed 0.20 milligrams per cubic meter concentration. The reason that the lead dust is considered to be the major hazard is that lead is an accumulative poison in the body and is not excreted.

The ventilation system should be designed in such a way that the total volume of air in

the range is changed from 20 to 40 times per hour. A steady, positive flow of air toward the backstop at a velocity of 50 ft per minute is the acceptable minimum.

Noise Reduction

The discharge of any firearm creates a muzzle blast which has the capability of affecting hearing. Prolonged exposure to such noise levels can inflict permanent, uncorrectable hearing damage. A firearm that fires a bullet which is transonic (more than 1,140 ft per second) generates the characteristic sonic "boom" which because of its high frequency component is even more damaging to hearing.

Even .22 caliber match bullets at times exceed the speed of sound at the muzzle, and this phenomenon is accompanied by the high whiplike crack which is sometimes heard in gallery ranges. Hearing damage, therefore, can result even from the .22 rimfire cartridge.¹

Noise Reduction on the Range

The walls, ceiling, and floors of a gallery range may be treated with effective sound absorbent materials.

The wall area next to the firing line and the ceiling directly above and for 2 or 3 ft in front

¹Ref.—Acton & Forrest—Noise & Hearing, *Journal of the Acoustical Society of America*, April 1968

TO BE INCLUDED AS ALTERNATE IN LIEU OF
45° BACKSTOP FOR ALL PROJECTS (SEE NOTE 9).
DETAIL AT 1/8" SCALE ONLY.

Fig. 4 "Venetian blind" type bullet trap.

General Notes on Fig. 4

1. Walls shall be 8 in thick; concrete or solid masonry units, providing minimum STC of 50.
2. Target range construction above or below occupied space shall provide minimum STC of 50.
3. Floor shall be concrete.
4. Construction above target range may be one of the following types, provided requirements for fire-resistive construction of the project are met:
 - (a) concrete flat slab or concrete slab and beam
 - (b) open-web steel joist
 - (c) concrete ribbed slab
 - (d) steel deck construction

For type (a) provide baffles at lights, beams, and other obstructions only. For types (b), (c), and (d) baffles shall be arranged so that only the baffle surface is visible from the prone firing position.

5. Information for each target range:
 - a. Number of firing booths required.
 - b. Positions required for target locations: 21'-0"; 45'-0"; 50'-0"; 75'-0"; and 100'-0". (If the 100-ft position is not required, locate the backstop at the 75-ft position and shorten the length of range accordingly.)

- c. Minimum width of firing booth, if greater than shown.
- d. Type of target carriers required (bullseye, silhouette, oscillating).
6. Structural fiberboard
Flame spread: 0 to 25
NRC: .65
Size: 32 × 72 in (or as required)
Color: Factory-finished white
Installation: As shown
7. Provide waiting room, ammunition storage space, and toilets.
8. Ventilation requirements: Mechanical exhaust at plenums #1 (35 per cent) and #2 (65 per cent) necessary to maintain minimum air flow of 40 ft/min across the net open area of the firing booths. Exhaust capacity to be 110 per cent of mechanical supply ventilation.
9. Standard venetian blind trap is composed of 4 louver plates with total height = 7'-0" ±, and depth = 4'-0" ±. Manufacturers' dimensions may vary from this requirement on shop drawings for nonstandard installations. For this alternate reduce length of range, if feasible without altering overall design. Otherwise, the additional 7'-0" should be added to the space behind the firing booths.

* Definitions of terms used in table:

Hz = frequency of the sound wave in cycles per second

Coefficient of absorption = percentage of sound absorbed by the given material

of the firing line should be treated with mineral fiber acoustical tile, which is a better material for this area since fiber glass will tend to be loosened by muzzle blast and drift down onto the shooters. It will also collect unburned powder and, eventually, may create a fire hazard.

Any maintenance painting should be done with a spray, so that the holes in the tile can be kept open. These holes are the effective sound absorbing part of the tile.

Carpeting the firing line and any assembly area to the rear will help considerably. Carpeting in front of the firing line can accumulate unburned powder and thereby creates a fire hazard.

The protective baffles described in the section on range interior can serve a dual purpose as sound baffles, in that they help to break up the natural resonances which are so often set up in large open spaces.

If the side of the baffles facing the firing line is faced with an acoustic insulation material, they will help to absorb some of the unwanted sound.

The breaking up of large, flat, smooth surfaces (in a range) which can reflect sound easily is one of the big factors in producing a pleasant shooting area. There is a long list of sound-absorbing materials which have been used on indoor ranges. The coefficient of absorption in the table above represents the percentage of sound energy which is absorbed by the surface described.

The table clearly shows the greater efficiency of soft, heavy materials with open-pored surfaces in the absorption of noise over materials with flat smooth surfaces. It also shows how ineffective building materials such as brick, plywood, concrete block, etc., are in the absorption of sound. The greater absorption efficiency at low frequencies (125 to 500 cycles per second) of the mineral fiber tile is readily apparent. The superiority of fiber glass in roll form at the middle and high frequencies is also clearly indicated. The discussion above pertains to noise within the range itself, and to techniques which can be used to absorb sound within the range area.

There is another field of consideration in the noise problem. This is the problem of sound transmission to the area outside the range. This noise escapes the range and annoys residents who have no interest in or connection with the range operation. Such noise will be a constant irritant to these persons, and for harmonious relationships with the community,

an effort should be made to reduce this noise to a minimum.

Since sound requires air for easiest transmission, it follows logically that the first corrective step is to block off any air leaks out of the range. It is patently impossible to seal off the range completely, but all doors can be weatherstripped, and, if necessary, a double door system may be installed (without the two doors facing each other) to form a combination entrance and sound trap.

Intake and exhaust of air should be accomplished through muffling chambers. The chambers should be maze baffled in a manner which requires the air to flow around corners. The muffling action thus achieved is very similar to that of an automobile muffler.

If the problem of sound transmission is acute, special measures may have to be taken in the layout and construction of the range. In planning and construction of an indoor range which is to be in a multipurpose building, it is strongly recommended that a competent acoustical consultant be retained.

Target Carrier Systems

An indoor range can be run much more efficiently and safely if some sort of target transport system is installed. A carrier system may be constructed of bicycle wheels and clothesline if funds are not available for anything else. On the other end of the expense spectrum, a completely automatic electrically powered system may be purchased from any one of several reputable target equipment companies.

Regardless of what target handling system is selected, targets should normally be placed with their centers approximately 5 ft off the firing-line floor level for the rifle standing and pistol position; and about 18 in. from the same level for the prone, sitting, and kneeling positions. Low target positioning is usually accomplished by the use of a detachable extension rod on the target carrier. If registered tournaments are to be held on the range, provision should be made for attaching backing targets, since they are required for all NRA Registered Smallbore Rifle competitions.

Although indoor pistol tournaments may be held without turning targets, it is strongly recommended that such targets be used. Even though this type of target holder is more difficult to construct than the simple trolley target carrier, it is still entirely feasible to construct using easily available parts.

An indoor range may be used for police firearms training. Usually the B27 target, or a reduction of that target, can be used or adapted to the standard target holder. There are special considerations for safety in police combat shooting indoors. Write NRA for further information.

Range Equipment

Ranges will normally require accessory range equipment which provides a more comfortable and pleasant place to shoot, as well as helping to increase the safety factor.

Gun racks should be placed in convenient locations, both to the rear of the firing line and in the assembly area. These racks should be constructed so as to allow the secure placement of match target rifles with scopes in them without danger of damage.

Hand-gun benches should be provided on the firing line for pistol ranges. If a range is to be used for both rifle and pistol, removable or folding pistol benches should be installed.

Trash receptacles of at least two types should also be provided—one for the spent cartridge cases, and one for other trash.

Coat racks are a necessity. They can be placed wherever convenient in the assembly area or in a special room.

Storage cabinets for target and miscellaneous items should be provided.

A bulletin board should be put up on a wall in the assembly area so that tournament scores and other pertinent information may be posted.

Shooting mats are very nearly a necessity for an indoor range. They can be purchased from one of several manufacturers, or may be cut very cheaply from used rugs, rubber matting or other suitable material.

Seating should be provided in the assembly area as well as in the area behind the firing line.

Other Space Requirements

Auxiliary rooms which should be provided for if at all possible are:

- * A secure room for stowage of guns and ammunition. This room should contain space for cleaning guns and a small shop for minor repairs.

- * An assembly and spectator area within the firing range room, but separated at least by a rail, should be provided. If possible, the assembly area should be cut off from the actual firing area by a waist-high partition with glass above so that firing may be observed and conversation may occur without disturbance to the shooters.

- * A combination classroom and statistical office room should be completely separated from the range area. This will provide capability for statistical work during tournaments.

- * Rest rooms should be provided, and undoubtedly will be required by law.

- * A snack bar or restaurant is a very desirable addition to a shooting facility. In some instances, this facility augments the range income.

- * An office for the range manager should be provided if not provided in the statistical office.

- * A coat room or locker room is a desirable addition to any sporting facility, and shooting ranges are no exception.

- * Last, but not least, a utility room containing furnace, air conditioning equipment, electrical switch panels, floor cleaning equipment, and so forth, should be provided for all indoor ranges.

SHOOTING RANGES, OUTDOOR

By WALTER L. COOK

TRAPSHOOTING

Trapshooting is the oldest of artificial clay target shooting sports. It is derived from an old live bird shooting game which originated in England in the latter part of the eighteenth century. A few years later, in the early 1800s, some English shooters formed a club called the "High Hats." The name was derived from the fact that the gentlemen in the club used their discarded high hats to "trap" live birds. A high hat with a long string attached to it would be placed out in front of the shooter, and a live pigeon would be placed under the hat. When the shooter was ready he would tip his hat and the "trap boy" would jerk the string that would pull the hat from over the pigeon; thereby, releasing the pigeon as a live target for the shooter.

In the latter part of the nineteenth century glass balls were introduced as artificial targets for trap shooters. The glass balls were filled with feathers so that when they shattered the floating feathers would make it appear as though a bird had been shot. This was the evolution of artificial targets, and it was not long thereafter that clay targets were introduced.

Layout Actual space required for trapshooting is a site 100 yd wide by 300 yd deep. The trap is located midway of the short side and throws targets at varying angles from the five shooting positions. The shooting positions are located 16 yd behind the trap and 3 yd apart. Each firing position is 16 in. wide. Additional firing positions are located at 1-yd intervals up to 27 yd from the trap. These additional firing positions are used for handicap shooting. In handicap shooting, the persons with greater shooting ability shoot from a greater distance.

When a target is thrown from the trap it rises from ground level to a height of 8 to 12 ft. It reaches its maximum height at a point about 30 ft in front of the trap, thus making it about 78 ft (16 yd plus 30 ft) from the firing positions located on the 16-yd line. The target will carry about 48 to 52 yd from the trap. The trap can be adjusted to control the throwing distance, and usually it should be set to throw close to 48 yd since this means the target will be moving slower and better scores will result. This is particularly important where shooting is strictly recreational.

A trap-field layout is illustrated in Fig. 1. It may be observed that targets may be thrown at up to a 47° angle away from the straightaway. The usual and recommended practice is to keep targets within an angle of 22° to the left or right of the straightaway. This will make for better scores and happier shooters.

The Game A trap squad is comprised of five members. Each member of the squad fires at 25 targets to make a regulation trap "round." Each squad member shoots five shots from each of the five firing positions.

With all five members of the squad lined up on the 16-yd line, each shooter, progressing from position one on the left to position five on the right, fires at one target. This procedure is repeated four more times until each has fired five shots from each starting position. The shooters then rotate to the right one position, with the shooter on position five moving to position one. This procedure is followed until the round is completed and each member of the squad has fired five shots from each position.

While on the shooting line, only the shooter whose turn it is to fire has a loaded gun. The man to the right of the shooter may drop a shell into the chamber while the shooter is firing, but all other guns should be empty and action should be open.

The usual trap gun is 12-gauge but it may be smaller. Any conventional action type will do for singles trapshooting. The shooting distances involved cause most trapshooters to favor guns with 30- or 32-in. barrels, full choke, and raised solid or ventilated ribs. Since in the doubles game, two targets are thrown at the same time, a gun capable of firing two quick shots is required.

The American Trap Association rules specify that shot size shall not be larger than #7½. Shot shells are not to be loaded with more than 3 drams equivalent powder and not more than 1½ ounces of shot.

Walks The appearance of the trap field can be enhanced by having the surfaces of the shooting stations and walks made of such materials as gravel, asphalt, or concrete. The walkways for the five shooting stations, extending from the 16-yd line to the 27-yd line, should have markers or painted lines placed at 1-yd intervals, preferably with yardage numerals indicated.

Skeet Shooting

The short-range clay target game or skeet was originated by William Harnden Foster in 1926, at Andover, Massachusetts. It was designed to approximate field shooting at birds such as quail, grouse, doves, etc.

In its beginning it was known as "shooting around the clock." The original layout had one trap located at twelve o'clock which threw targets over six o'clock. Shooters progressed around the entire perimeter of the clock shooting at various angles. Later a second trap was located at six o'clock permitting shooters to fire at the same number of angles while going halfway around the clock. This reduced the shooting zone in half and thereby increased safety.

The skeet layout today is very similar. The targets are thrown from a high house and a low house located at opposite ends of a semicircle.

The Layout The layout for the single skeet field is shown in Fig. 2. The minimum site for the actual shooting area must be 600 yd wide by 300 yd deep. The semicircle containing the trap houses and the shooting stations is located in the middle of the long side of the site. The site should face northeast or north if it can.

The two trap houses are 120 ft 9 in. apart. The high house is located on the left of the field and the low house is located on the right. Targets shot from the high house start at a point about 10 ft above the ground. Targets shot from the low house start at a point about 3 ft above the ground. Both traps throw targets at fixed angles. The lines of flight cross each other at a point 18 ft beyond station eight and at a height of about 15 ft. The average flight distance of a skeet target is 55 yd.

There are eight stations on a skeet field. Station one is located at the base of the high house, on the left side of the semicircle. The next six stations progress around the semicircle, with station seven located at the base of the low house. Stations one through six are placed 26 ft 8½ in. apart. Station eight is located at the midpoint of a line perpendicular from the high house to the low house.

When electrical traps are used, the electrical control setup is located 12 ft to the rear and left of station four.

Eight-foot squad boxes are located six feet to the rear of stations one through seven.

A short gun pattern panel is desirable near the range to "sight in" a gun.

If possible four skeet fields, side by side and touching so as to use common high-low houses, are desirable for economy of construction, ease of management, and as a necessity for holding large matches.

The Game As in trapshooting, the skeet squad is normally composed of five men, and 25 shots make a round for one person. In the course of a round, a person will shoot at targets thrown one at a time from both the low house and the high house. The shooter will also fire at double targets, one target being fired from each of the trap houses simultaneously. In a round, there are sixteen singles shots, eight shots fired at four doubles, and one optional shot. The sixteen singles are shot two at each of the eight stations. The eight shots for the four doubles are fired two each at stations 1, 2, 6, and 7. The first time a target is missed, the optional shot is used as a repeat shot. If during the round of 24 shots there have been no misses, the optional shot may be taken as a single fired from any station, usually from station seven.

To begin a round, a squad moves to the squad box behind and to the right of station one. The first member of the squad moves to station one to commence shooting. Other members of the squad remain in the squad box with guns unloaded and with actions open. After the first shooter assumes the ready position with his gun at his shoulder, he calls "pull." Within one second a target appears from the high house. If the shooter is accurate or lucky he will break the target at about 20 or 25 yd from the trap house. After his first shot at the target from the high house, the shooter assumes his ready position for the target to come from the low house and then repeats the same procedure as for shot one. After the second shot from station one, the first shooter returns to the squad box and waits until the other four shooters have completed the same sequence of shots. The squad then moves as a unit to station two

SHOOTING RANGES, OUTDOOR

Trap Field

to repeat the same procedure. After shooting singles at each of the eight stations, the squad returns to station one to commence shooting doubles. The shooters conduct themselves in the same manner as described for the singles. When the shooter calls "pull," targets are released simultaneously from the high house and the low house. The shooter fires first at the target moving away from him and then at the target moving toward him.

All gauges and types of guns may be used in skeet shooting. Since doubles are fired in each round, it is necessary to have a gun that will fire two shots in rapid succession. The short-range gunning makes short-barrelled, open-bored guns most popular.

There are four gauge classifications in skeet championship events: (1) an all-bore event in which any gauge gun may be used but in which the .12-gauge is usually favored, (2) .20-gauge

event; (3) small bore, using .28-gauge or 410 with 3-inch shells, and (4) sub-small bore, 410 with 2½-in. shells. No shot size smaller than #9 may be used in a match sanctioned by the National Skeet Shooting Association.

Trap Houses The trap house houses the target throwing equipment and can be constructed of many materials.

Fig. 1 Trap field. From *Outdoor Sports Facilities*, Departments of the Army, Navy, and Air Force, Washington, D.C., 1975.

Specifications for Trap Field

Recommended Area Allow 16 acres for a single field. Shotfall danger zones of adjacent fields partially overlap and require only 3 acres additional land.

Size and Dimension Walks and structures occupy an overall area approximately 100 ft deep by 65 ft wide. Minimum cleared area is a section with a radius of 100 yd (1.7 acres). Shotfall danger zone is a section with a radius of 300 yd (14.8 acres).

Orientation Preferred orientation is for the centerline through shooting station #3 to run north-east-southwest with the shooter facing northeast.

Surface and Drainage Shooting stations are to be portland cement concrete (PCC). Walkways may or may not be paved. Shooting area and 100-yd-radius minimum cleared area are to be turf. The 300-yd radius shotfall danger zone may be turf or water or left in natural condition, and the entire field should be located in a relatively flat area with an open background.

Special Considerations If shooting is entirely over land, there should be safety provisions for fencing, posting of warning signs, and clearing away of concealing brush. If shooting is over water, warnings posted on buoys or other signs are required, and the trap house should be back far enough from the water's edge to permit recovery of unbroken targets. Contact the National Rifle Association for information on trap house construction and trap machines.

SHOOTING RANGES, OUTDOOR

Skeet Field

SKEET FIELD LAYOUT

SHOTFALL DANGER ZONE

Fig. 2 Skeet field. From *Outdoor Sports Facilities*, Departments of the Army, Navy, and Air Force, Washington, D.C., 1975.

Specifications for Skeet Field

Recommended Area Allow 29 acres for a single field. Shotfall danger zones of adjacent fields partially overlap and require only 2 acres additional land.

Size and Dimension Walks and structures occupy an area approximately 130 ft wide by 80 ft deep. Minimum cleared area is a semicircle with a radius of 100 yd (3.25 acres). Shotfall danger zone is a semicircle with a radius of 300 yd (29 acres).

Orientation Preferred orientation is for the centerline from station #4 through station #8 to

run northeast-southwest with the shooter facing northeast.

Surface and Drainage Shooting stations are to be portland cement concrete (PCC). Walkways may or may not be paved. Shooting area and 100-yd-radius minimum cleared area are to be turf. The 300-yd-radius shotfall danger zone may be turf or water or left in natural condition, and the entire field should be located in a relatively flat area with an open background.

Special Considerations If shooting is entirely over land, there should be safety provisions for

fencing, posting of warning signs, and clearing away of concealing brush. If shooting is over water, warnings posted on buoys or other signs are required, and skeet houses should be back far enough from the water's edge to permit recovery of unbroken targets. Contact the National Rifle Association for information on skeet house construction and trap machines.

SHOOTING RANGES, OUTDOOR

Combination Skeet and Trap Fields

Fig. 3 Combination skeet and trap field. For layout dimensions and details see Fig. 2 (Skeet) and Fig. 1 (Trap). If paved, walks should be 4-in concrete reinforced with 6 × 6 in, No. 6 gauge welded wire fabric or bituminous.

Specifications

Recommended Area Allow 30 acres for a combination field.

Size and Dimension All walks and structures occur within an area approximately 130 ft wide by 115 ft deep. Minimum cleared area is contained within two superimposed segments with 100-yd radii (4 acres). Shotfall danger zone is contained within two superimposed segments with 300-yd radii (36 acres).

Orientation Preferred orientation is for the centerline from skeet station #4 through trap station #3 to skeet station #8 to run northeast-southwest with the shooter facing northeast.

Surface and Drainage Shooting stations are to be portland cement concrete (PCC). Walkways may or may not be paved. Shooting area and minimum cleared area are to be turf. Shotfall danger zone may be turf or water or left in natural condition, and the entire field should be located in a relatively flat area with an open background.

Special Consideration If shooting is entirely over land, there should be safety provisions for fencing, posting of warning signs, and clearing away of concealing brush. If shooting is over water, warnings posted on buoys or other signs are required, and the trap house should be back far enough from the water's edge to permit recovery of unbroken targets. Contact the National Rifle Association for information on skeet and trap house construction and trap machines.

MARINAS

SITE PLANNING

Orientation This facility should be located reasonably close to the water to expedite the dispersal of rental equipment and the performance of routine maintenance. However, careful consideration should be given to insure that the building is not located in an area subject to flooding or storm damage. The maintenance shop should have ready access to the water by overhead crane, mobile equipment, or paved launching

ramp to facilitate transporting the boats from the water to the shop for repair. The lounge should be oriented with a view of the water, but late afternoon and evening sun glare should be avoided if possible.

Launching Area It is desirable to separate this activity from normal vehicular circulation in order to avoid congestion. This is usually accomplished by locating the ramp on a separate turnaround or side road. The ramp should be related directly

to the parking area with turnaround loop between them. The access road should be sized to allow another vehicle to pass. A paved ramp capable of launching two boats simultaneously should be provided as a minimum facility. The ramp slope should be constant and range between 12 and 16 percent. This should also include a tie-up area to be used for loading and unloading the boat without interfering with the launching operations. A minimum water depth of 4 ft is required to launch a boat from a trailer. An optimum guide

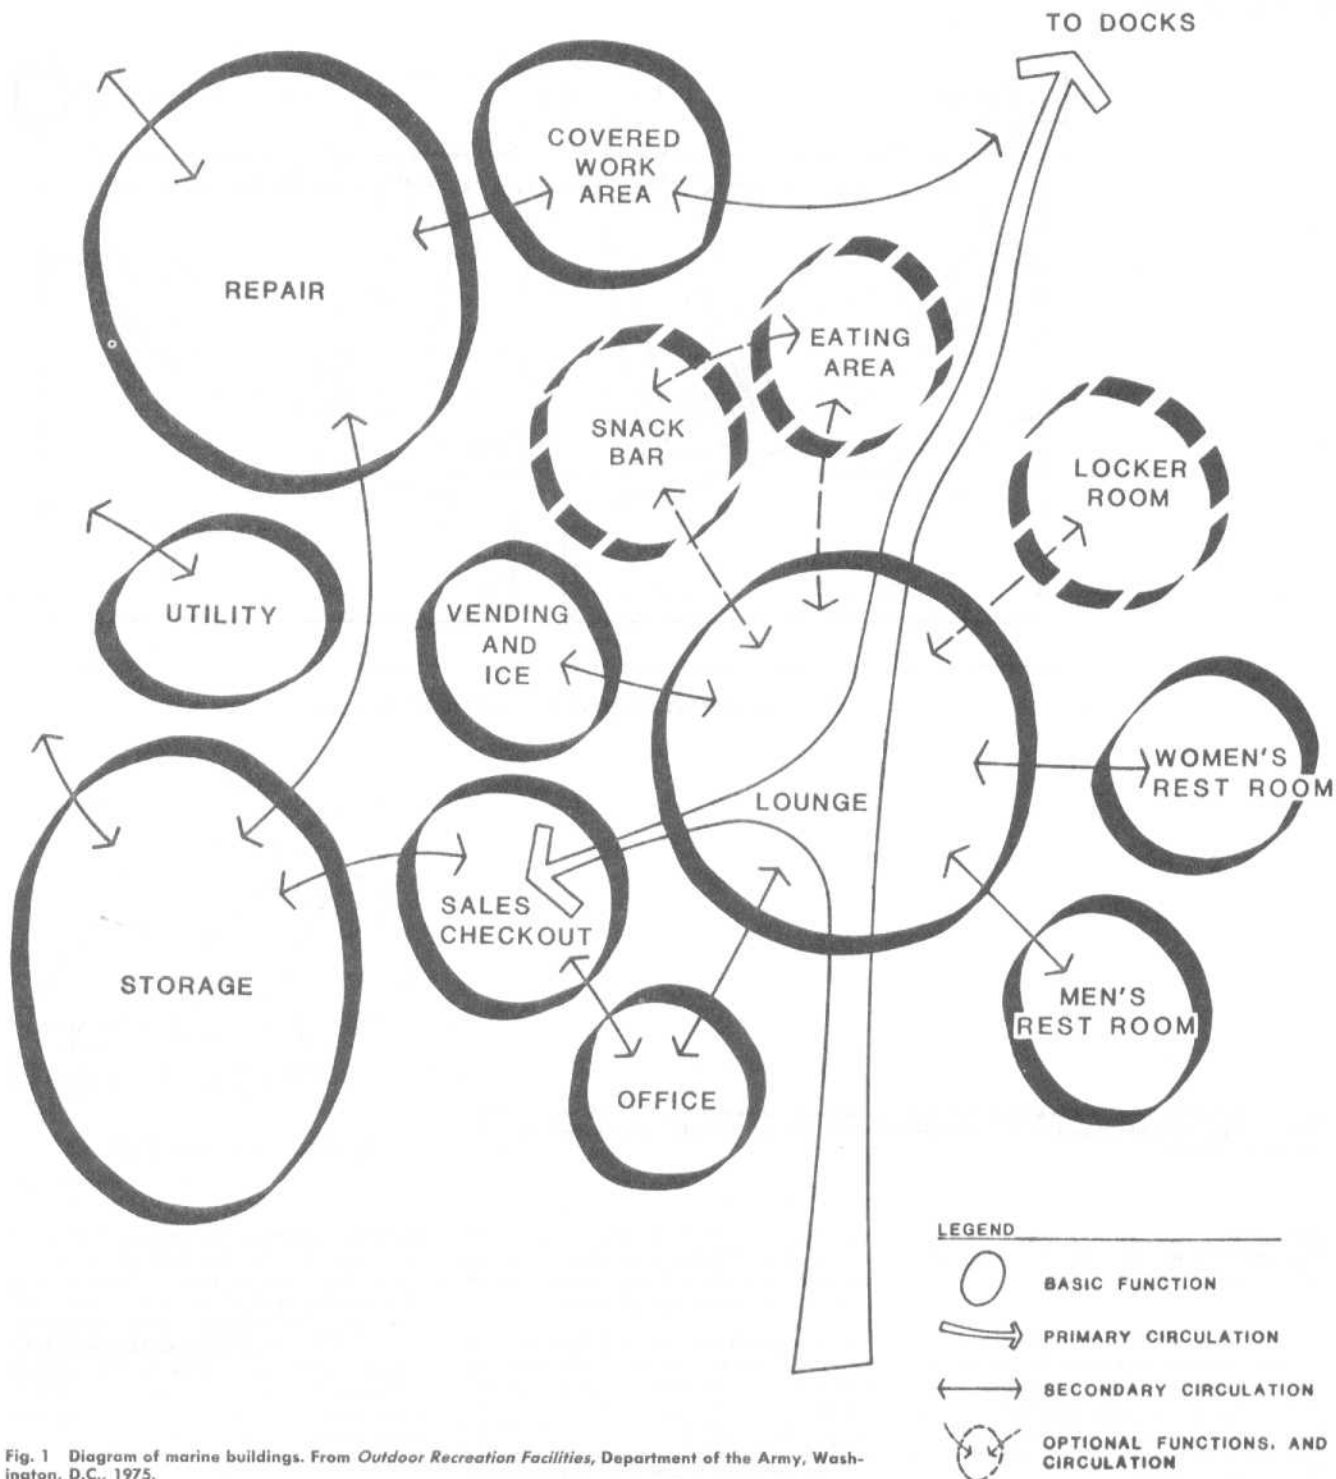

Fig. 1 Diagram of marine buildings. From *Outdoor Recreation Facilities*, Department of the Army, Washington, D.C., 1975.

MARINAS

for calculating the number of launching ramps on small bodies of water is indicated below.

- Water skiing—One boat per five acres of water. Assume that a maximum of 10 percent of total boats in water will be involved in water skiing. However, water skiing and fishing are incompatible activities in the same area of the water body.
- Fishing or pleasure boating—One boat per two acres of water.
- Canoes or rowboats—One boat per acre of water.
- Each ramp can handle 40 launchings per day.

Docking Facilities Floating docks are preferable to stationary docks where fluctuations in water levels exceed 1½ feet. Roofed docking facilities are preferred for rental motor boats in order to reduce weather damage and the maintenance time spent in bailing the boats. A sandy area is desirable for beaching canoes, skiffs, and small sailboats. This allows the boats to be turned over when not in use. If rental dock space is to be provided, a careful projection of the numbers and sizes of boats to be docked is necessary to insure

the correct sizing of docks and provide adequate maneuvering space.

Vehicular Circulation and Parking In addition to the normal parking requirements, a parking area for combination car and boat trailer parking should be provided. Each space should be a minimum of 10 ft wide and 40 ft long. The total number of combination spaces normally should not exceed 30 percent of the total parking.

BUILDING PLANNING

Building Levels and Construction A one-level building is preferred to accommodate the required circulation and room arrangement in the marina support building. Where topography requires,

however, a modest split in level can be planned by separating the boat-repair space from the rest of the building. Heavy flooring and framing will be needed for this space to permit storage of motors and use of an overhead crane.

Functional Relationships The sales/checkout room should be located between the main entry and the access point to the docks. From this initial contact point information, tickets, and rental equipment will be dispersed. The sales/checkout room should have direct access to the general storage area, so that rental equipment can be easily removed and returned. The storage room should be related directly to the repair shop for access to equipment and spare parts. Restrooms should be easily accessible from the dock area.

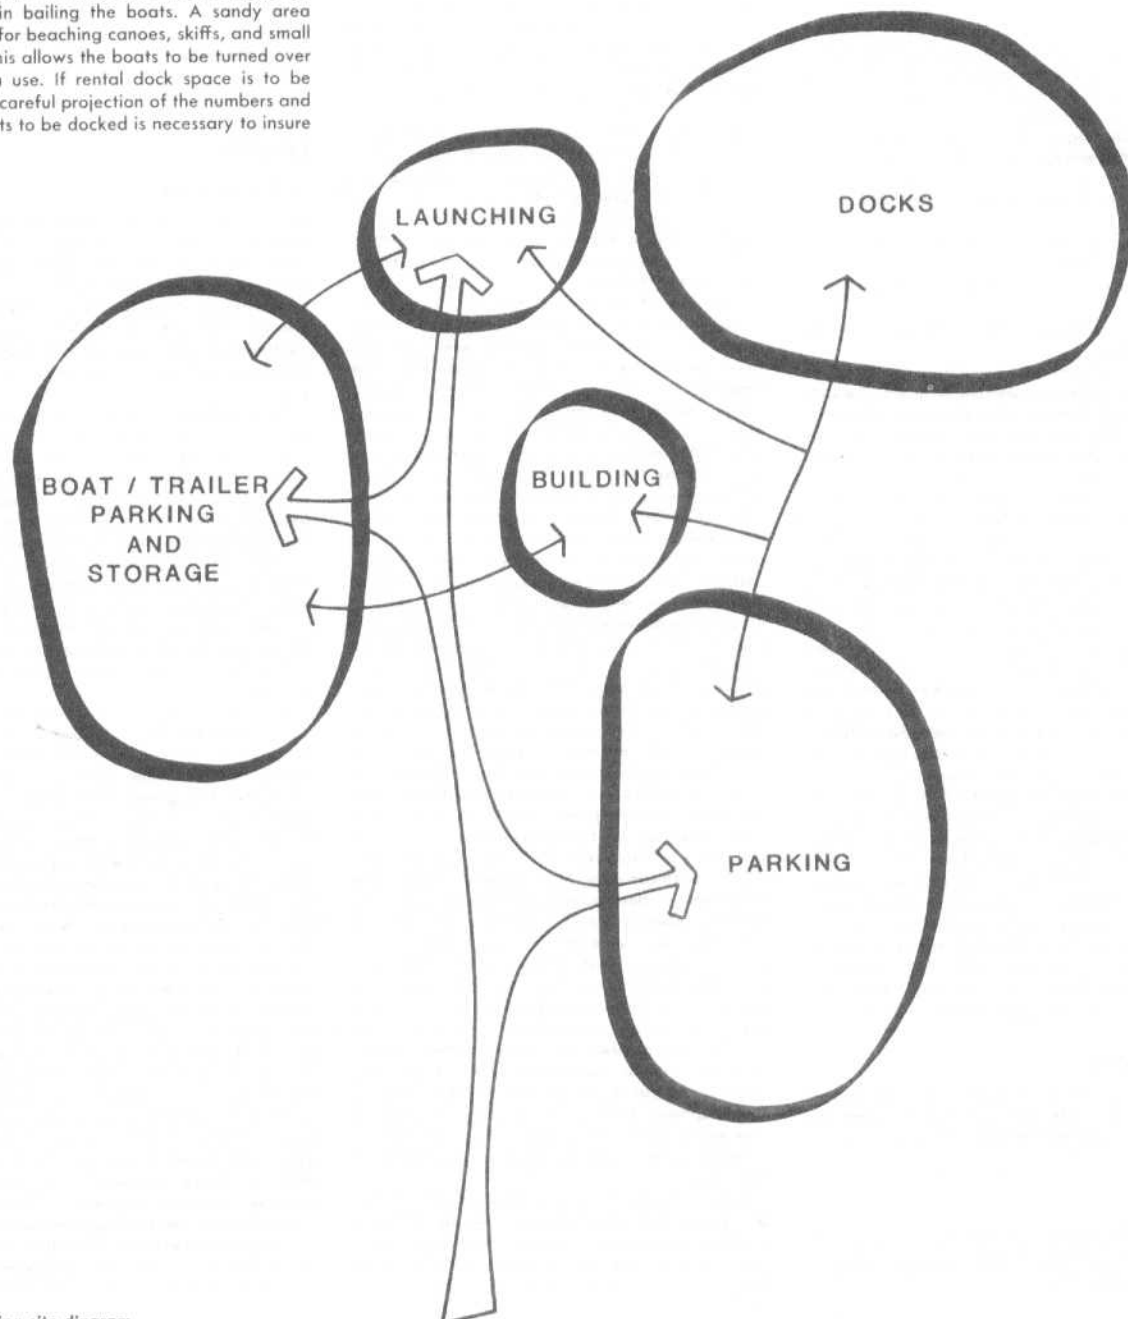

Fig. 2 Marina site diagram.

MARINAS

By CHARLES A. CHANEY

CLEARANCES

General

Clearances for any and all purposes within the offshore area of the marina should be considered as relative rather than as fixed values. When adequate water area is available, all clearances may be made quite liberal and limited only by the desires of the local boat owners and the financial ability of the responsible parties to pay for more extensive structures. The more serious problem of establishing proper clearances is faced when planning a marina for maximum capacity in a definitely fixed water area such as a frontage in a large municipality.

In the planning of a marina it is necessary to consider clearances that are by nature in three different classes and for three positions or operations of boats. These clearances are as follows:

1. Clearances in slips beyond the beam and length of the boat
2. Width of entrance and exit channels at the marina
3. Width of water area for maneuvering to and from slips

It is the purpose of this chapter to discuss these three items and present data from which the necessary clearances and widths of waterways may be determined together with the reasons for the recommendations so made. (See Figs. 1 and 2.)

Boatmen in various parts of the country evaluate clearances in different manners, and often a group is willing to make a larger initial investment to secure greater ease in maneuvering boats within the marina. The direction and velocity of prevailing winds and tidal variations in some localities may require larger clearance allowances to provide the desired measure of safety. Permissible clearances within slips equipped with traveler irons can be much smaller than those in slips providing cleats or rings only for the quarter lines. This is especially true when fluctuations in water level are more than about 2 ft.

Neither the establishment of the amount of clearance necessary for a typical marina, nor even proposing a set of rules whereby these may be determined, is considered as practical. It is, however, entirely reasonable and within the scope of this article to set up some clearances as suggested minima, which should not be decreased in the interest of safety and ease in maneuvering of the craft. The minimum clearances would appear to approximate those given in the following paragraphs.

Slip Clearances

The clear distances between the sides of the slip and the boats berthed therein must be sufficient to prevent the boats being tossed or

forced against the sturdy timber construction, thereby resulting in possible damage to both pier and boat. Clearances are required for a number of reasons such as safety of operation in moving the boat to and from the slip, compensation for the amount of slack in lines due to rise and fall of water from tides and during storms and freshets, and the prevention of damage to the superstructure of the boat when the water is rough and some rolling and tossing of the craft occurs. While it is essential that sufficient clearance be allowed in each slip, it also is advantageous to the engineers that these clearances be held to a reasonable minimum as a means of conserving space in the marina. (See Fig. 3.)

This thought can be made more impressive by the use of a simple example. Assuming that a group of 18 boats in slips are in a row along one edge of a pier, a reduction of 1 ft in the clearance on each side of each of the 18 boats would result in a gross saving in space of 36 ft. This would provide slips for two additional small-sized cruisers.

The size of the boat to be berthed will influence the side clearance in the slip. Large boats, due to their momentum, are more difficult to handle in restricted areas than the small ones. It is reasonable, then, to allow more clearance for the larger craft. The dimensions given in Fig. 4 for the minimum clear width of slips are based upon side clearances varying from 1 ft for the smallest boats to 1½ ft for boats up to 30 ft, and to 2½ ft for boats up to 80 ft in length. Figure 4, entitled "Dimension Diagram for Slips and Catwalks," illustrates several different arrangements of main walks, catwalks and slips and contains key letters, the values for which are given in Fig. 4. The controlling dimensions of this table assume the use of traveler irons and are typical only for the particular design of structure illustrated. No doubt other types of marina structures will be developed. In this event it is suggested that standards similar to Fig. 4 be prepared as a means of conserving the planners' time and standardizing the structures. These clearances and slip widths are considered sufficient for the sizes of boats given in the table when moderate tides up to 6 ft prevail and when the marina is in a location not subject to frequent storms with resulting high turbulent water. The engineer, in determining clearances and slip widths, should give consideration to the frequency and amount of high water in the basin together with other local conditions having a bearing on the subject. It is conceivable that these considerations will indicate the necessity for increasing the minimum slip widths and clearances recommended herein, and, as proper clearances are of primary importance for safeguarding of the vessels, the engineer should not hesitate in making any adjustments in these values he deems consistent with the conditions prevailing at the site.

Figure 4 contains suggested dimensions for all spaces that combine to make up full slip width allowances and the lengths of catwalks. Boat beams are in accordance with boat builders' catalogs and conform to Fig. 3. Slip

widths are based upon use of 2-ft-wide catwalks equipped with traveler irons. When 4-ft-wide catwalks are required, whether of the fixed or floating type, add 1 ft to the gross width of each slip. Throughout this article the figures used for beams and lengths of boats are intended to include all items such as bowsprits, fishing pulpits, tenders that project beyond the hull, etc. Slip lengths are 3 ft longer than gross boat lengths. Catwalks when not required to be full length of the slips, are usually two-thirds the length of small slips varying up to a 34-ft length for boats 50 ft or longer.

BUILDINGS

General Comment

The preceding dealt with the arrangement and construction of those parts of the marina which are along the water's edge or are built over the water for the accommodation of boats and the convenience of the boatman in performing his chores. The fixtures on shore comprise his headquarters, office, place of contact with fellow boat owners and his medium for relaxation.

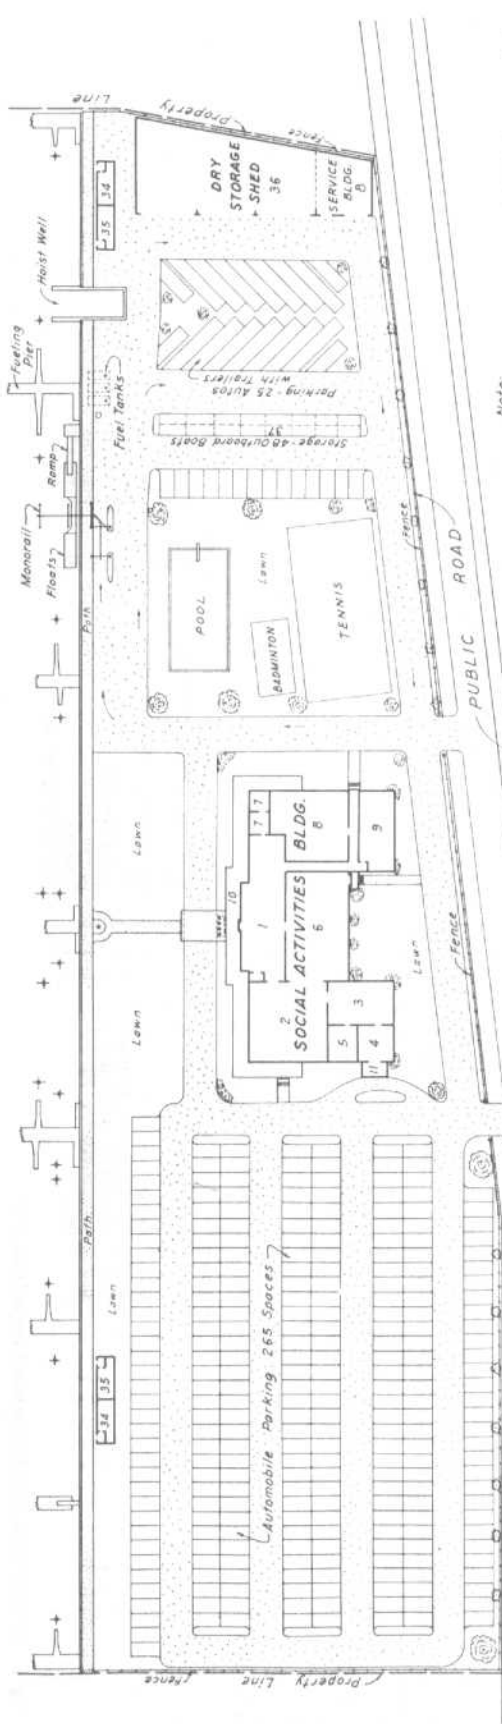

The buildings constructed on the grounds of the marina constitute one of the main features of the harbor, and while they are primarily to serve a practical purpose, their importance demands that full consideration be given to the style of architecture, the design, and materials used in their construction.

Due to the prominence of these structures on the site, well planned buildings of appropriate style, located in carefully arranged and landscaped settings, will add much to the charm of the marina. The development, in every way, should become a source of pride to the community.

From the viewpoint of the management, the shore installations, including buildings, shrubbery, trees, grassy plots and even the chairs or benches provided, take on a different significance. The great majority of visitors who approach the marina from the water probably are affiliated with some distant club or organization. On the other hand, many of the visitors from the landward approach and people passing along the highway adjacent to the marina may be potential future boat owners even though they may not own boats nor have more than a layman's knowledge of boating. It is logical that the first step toward their ultimate entree would be the presentation of a well arranged building or group of buildings in a pleasingly landscaped setting with an expanse of tranquil water in the background. Most people enjoy the beauties of nature and the artistry of man's handiwork. A pleasant setting may stimulate their interest in boating and small additional investment for beautification will pay large dividends in attracting new patrons who seek recreation afloat.

Conditions controlling the uses to which buildings are devoted, their size, design, type of architecture, and even the materials of construction, will not be constant throughout the

country, so a standard set of rules or recommendations cannot be suggested. An architect familiar with the local requirements should be employed to study the site and prepare plans for such buildings as are necessary in carrying on the activities of the marina.

In planning, a comprehensive scheme should be worked out covering present requirements and allowing for a reasonable amount of future expansion. When a well developed scheme based upon serious study of the problem is adhered to, future expansion becomes more practicable, less expensive to accomplish, and the ultimate development will be convenient and attractive rather than a conglomeration of poorly styled and located buildings which might otherwise result. The following paragraphs contain suggestions relative to styles of architecture, uses for buildings, designs and materials of construction.

The amount of floor space to be provided for the various activities in each of the buildings at the marina must be determined by local conditions and requirements. Several drawings

in this article show plans of buildings in the onshore areas of marinas.

Floor Space Allocations

The success of any marina, whether a private club, municipal or a commercial organization, is measured to a large extent by the opinion of the patrons as to the facilities furnished for the transaction of business and for their convenience. The buildings may be judged by the same yardstick; that is, satisfaction that a reasonable or justifiable amount of floor space has been provided for each of the activities involved. It is recognized that ideas differ greatly between any two communities and that operations may vary even between two marinas in the same vicinity. It would, accordingly, be unwise to adhere to a fixed rule on space allocation in buildings at marinas. However, the following paragraphs provide some comments that may be acceptable to the planner subject to modification to meet local requirements. Figure 5 also records data re-

garding space allowances in some marina buildings that may serve as a guide.

Social Activities and Administration Buildings

Buildings of these two types are strictly for the purposes of establishing the relationship between the marina and its patrons, conducting the business of the facility, administering to the needs and desires of the individuals and providing for the convenience and relaxation of the boatmen and visitors. Figure 5 shows one possible arrangement for a social activities building. This may be separated from other marina commercial activities such as sales and repairs. The building should be arranged and equipped for the conduct of such social functions as are compatible with the particular region. Refer to the table accompanying Fig. 5 for space allowances used elsewhere in social activities buildings. Administration buildings, both existing and planned, vary so greatly among marina sites that a suggestion as to room arrangement is considered inadvisable. They frequently consist of only an office, toilet rooms, furnace room, watchman's headquarters and a large lobby or lounge that may be used for group assemblies as required.

Sales and Service Buildings

Very little basic information, serving as a precedent, can be offered the engineer or architect for use in determining either the arrangement or the size of the sales and service building. These buildings must be proportioned to accommodate the amount and types of work expected to be performed.

Basically, a marina is not a boat building or repair yard, although it is often necessary or desirable that a certain amount of repairing be carried on within the marina, particularly when no responsible repair yard is at hand. Boat repairing done within a municipal or club marina generally is of a minor or emergency nature. On the other hand, repairing of boats and engines is one of the usual functions of the commercial type. The repair facilities, as well as sales accommodations, are accordingly more generously proportioned for the commercial than for the other types of marinas. When repair work must be performed outdoors, rules should be enforced to maintain the area in a neat and orderly appearance. Most repair and conditioning work seems to occur in the spring and autumn, when large numbers of boats are being fitted out for the oncoming season or being laid up for the cold months.

It is very difficult to judge in advance the amount of work of this nature which may be expected at any one time, since an abrupt change in weather can result in a sudden avalanche of business. Capacity should be provided for hauling at least one large and one small boat at the same time. It is suggested that the repair shop of the municipal marina be arranged for the servicing of boats up to 36 ft in length. Facilities of the commercial marina should possibly accommodate boats up to 50 ft long. If no other repair facilities exist in the community, it might be advisable to increase these lengths. The shop space, in addition to accommodating the boats under repair, should provide for the storage of parts and for necessary power tools and adequate room for the use of special handling or other mobile equipment.

The front part of the service building can readily be partitioned off with a show window and used for the display of boats and equipment to be sold. Floor area and headroom re-

Recreation and Entertainment

MARINAS

Fig. 6 Boat launching areas.

quirements will depend upon the number, size and types of craft to be displayed, along with space for racks, bins and counters for motors and supplies. Sailboats are best displayed under full sail, and it must be remembered that cruising craft will require additional space for boarding stairways. A ceiling height of approximately 16 ft is sufficient to accommodate most motor powered boats up to 40 ft in length, but greater heights are necessary for sailboats, again depending upon the size. Marinas using Travelift, Algonac or similar hoists to handle their display craft must also take their height into consideration.

In the event no separate administration or special activities buildings are erected, it is advisable that suitable lounge and extra toilet facilities be provided in the service building. Refer also to Fig. 5 for floor allowances that have proved satisfactory at other sites.

Pump and Engine Houses

The enclosures for fuel pumps, and the motors and engines operating boat handling equipment should be only sufficiently large to house the units with a small allowance in floor space for

their operation and maintenance. They should be of reinforced fireproof construction with lightweight roofs to lessen the horizontal force of any fuel explosions which might occur.

Covered Storage

Buildings on land for the dry storage of medium and large sized boats offer the greatest flexibility of operation, and therefore a maximum of use, when the floors are reasonably free of columns and similar obstructions. The capacity and arrangement must be determined locally from studies made of the numbers and

Swimming Docks

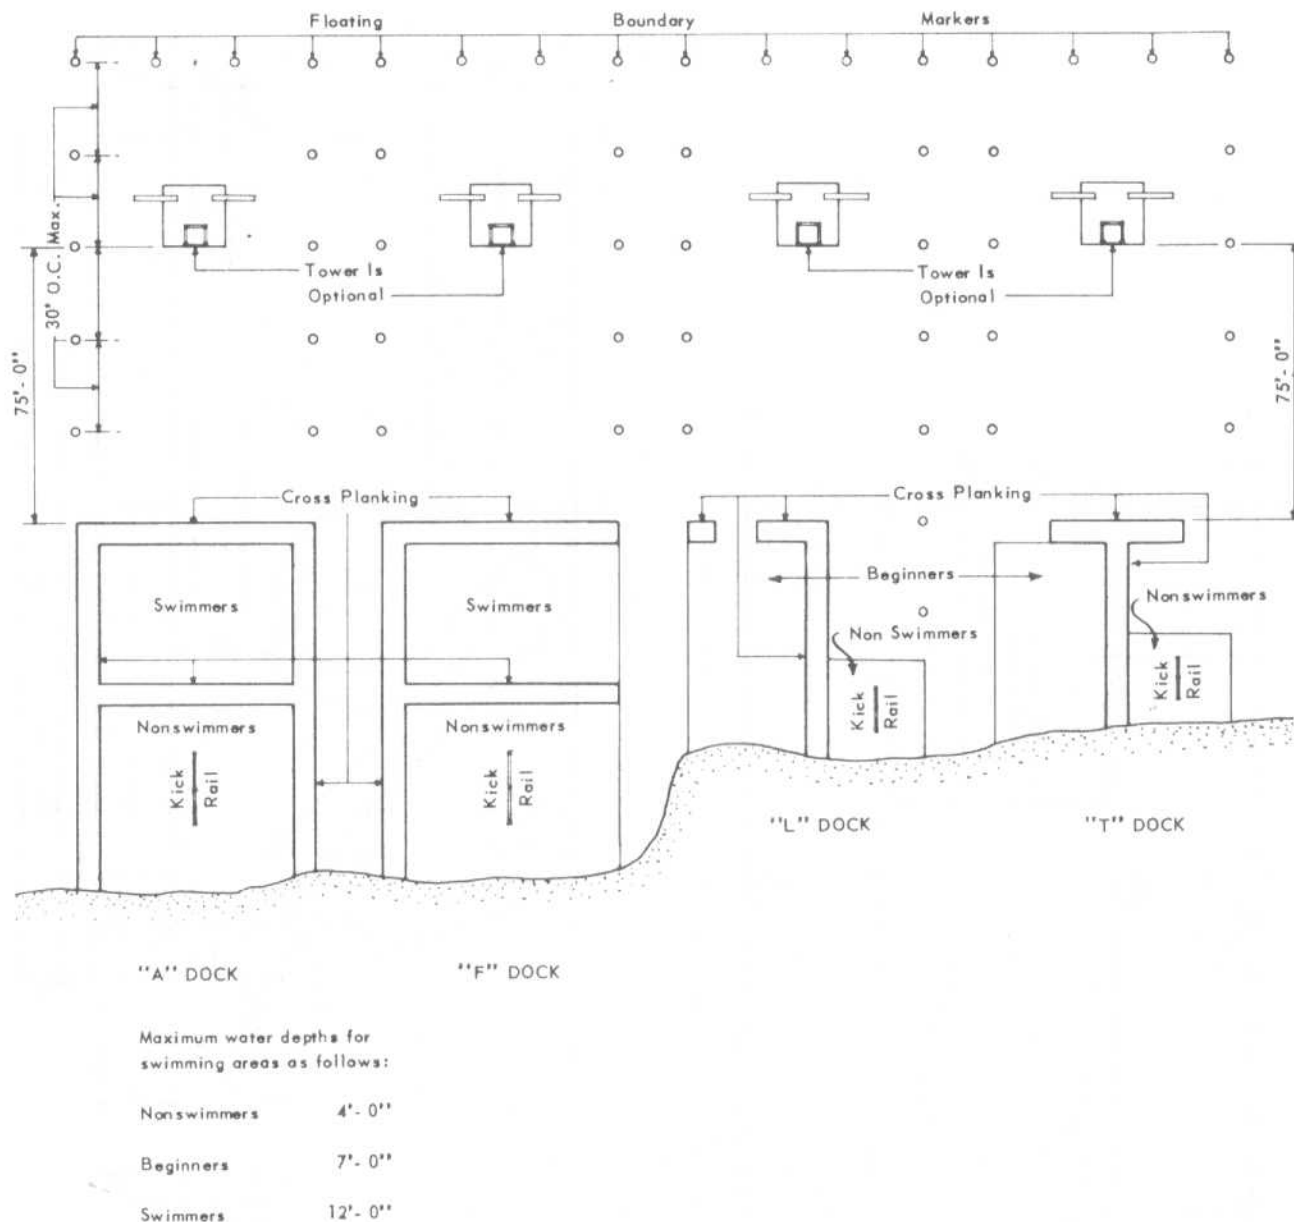

Fig. 8 Types of swimming docks.

sizes of boats that are likely to be so stored in the marina. Storage buildings frequently have no doors although they are basically for winter use.

In-season dry storage of small inboard and outboard boats, usually less than 21 ft long, is rapidly expanding and is applicable to about one-third of all boats of these sizes using the marina. The owners of these boats do not desire to keep them in slips during the season and are unable to store them elsewhere on trailers. Storage sheds for the craft should be supported by a single row of columns so spaced that brackets thereon will cradle the boats. Boats may be stored on each side of the columns and usually in three tiers. One type of these sheds is provided with rolling doors on

triple tracks on each side. Another type has no doors but is provided with a roof that projects from 3 to 5 ft beyond the stored boats.

Storage lockers for boat owners should be provided to accommodate such items as outboard motors, sails and gear, cushions, flags, lights and other removable items from runabouts and other open craft. This locker space may be provided in any of the marina buildings ashore. Because of the great weight of these lockers and the stored gear, they should not be placed upon the piers or walks of the marina.

BOAT LAUNCHING AREA

Wisconsin Conservation Department supplies these two boat pier and launching sites with

car and boat trailer parking spaces for limited areas. (See Figs. 6 and 7.)

SWIMMING DOCKS

Four different types of swimming docks are here given to afford a choice depending upon the age group of the swimmer and the swimming ability of the individual. Note that all four provide a kick rail to aid in swimming instruction. The extent of the swimming docks out into the water will depend largely upon the gradient of the bottom, allowing greater or lesser area for nonswimmers. Note that a maximum water depth scale is indicated to guide in the establishment of bottom gradient. (See Fig. 8.)

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

To determine the best possible layout for a particular site, a clear understanding of established principles and standards is necessary. The application of these principles will be affected to some extent by the character of the particular site and its location, but this should not be considered sufficient reason to lay aside well-proven fundamentals.

The following principles (except statement on multiple-camp reservations) apply in the layout of a short-term camp, a single long-term camp, and each camp in a multiple-camp reservation. (See Fig. 1 and Tables 1 to 4.)

Troop Sites Give first priority to the location of the troop campsites. Consider these needs:

- Good terrain with not more than 7 percent slope.
- Approximately 3 to 4 acres of usable land to provide for 6 to 10 patrol sites (2 to 4 to be used at one time).
- Good drainage to provide runoff and to permit disposal of waste water.
- Soil to permit driving of tent stakes.
- Cover—sod and/or trees depending on the site.
- Spacing—troop sites to be at least 450 ft apart, center to center, and at least 450 ft from any program area or building.
- Distance—maximum distance from a troop site to such points as the waterfront or central lodge should be about 1,800 ft. In some instances, troop sites have been successfully located up to 2,500 ft from the central area of the camp, but travel time should be considered.

Central Area After troop sites are tentatively located and program features noted, an area of approximately 10 acres should be selected for installation of central service facilities to serve all troop sites. Most of the camp buildings will be in this area so the terrain should provide good building sites. Consider these factors:

- Entrance road will be built to this area.
- Parking area should be located so all visitors park autos prior to entering the central area.
- Picnic area for visitors should be close to the parking lot, but not in the central area.
- Administration building should be readily seen and accessible from the parking lot so people entering camp will go there first.
- Health lodge should be convenient to both the administration building and food service. It should also be in a reasonably quiet area.
- Central shower should be convenient to troop sites and, if it includes staff toilets, should be close to the staff tenting area.
- All buildings in the central area should be accessible by service road.
- Avoid crowding buildings. Take advantage of terrain and tree cover to screen and separate buildings.

TABLE 1 Requirements for Short-Term Camp or Reservation*

Land and troop sites	Program facilities	General service facilities
Minimum requirements		
100 to 200 acres minimum recommended	Scoutcraft activities areas: Nature-conservation Ropes, knots, and pioneering	Water system—supply, storage, and distribution Access road Parking area with control gate Service roads Trails
10 to 14 troop sites, each with latrine, patrol tables, and fireplaces; water at each site or nearby; two-boy tents for shelter	Field sports area: Orienteering	
Additional facilities as dictated by need and program		
	Picnic area Chapel Campfire circle Additional program areas as dictated by staff available	Residence for camp ranger Maintenance facilities Activity shelters for severe-weather use First aid facilities Service building for use in: Campmaster program (staff) Meetings Storage and issue of equipment Training courses Explorer activities Electricity to residence and service building
Additional requirements for camps serving large numbers of troops		
Additional acreage on the basis of 200 acres per 10 to 14 troops Troop sites as needed	Provide separate program facilities for each camp—serving 10 to 14 troops—of the reservation	Provide separate facilities for campmasters in each camp—serving 10 to 14 troops—in the reservation.

* Typical conditions: accessible (within 1 hour's drive); year-round use; maximum use—4 to 14 troops at one time.

- Consider need for access by campers, installation of utilities, health and safety measures, drainage, ventilation, sunshine, and conservation measures.
- The area will be seen and used regularly by visitors and campers, so aesthetic factors are very important.

Access, Protection, and Control Establish a single entrance to the property. It is wise to provide one or more additional points of access for emergency use only; but, whenever possible, all regular access should be at one point.

The camp entrance should be at a point on the public highway where it can be seen easily and where it will permit safe entrance and exit for vehicles.

AQUATICS

A full aquatics program is a great asset to a long-term camp. To provide facilities for swimming, diving, lifesaving, boating, canoeing,

sailing, and fishing will require a fair share of the construction budget and a good deal of study and planning on the part of the camp-development committee. Obviously, it is not possible to offer all phases of the aquatic program at camps in some parts of the country.

Most states have health laws governing the construction and operation of swimming places. Ask for advice and assistance of state and local health authorities at the beginning of the project. The use and impoundment of waters is generally controlled by law and riparian rights. Check all legal aspects of plans to use, divert, and impound natural waters.

Construction of a dam or swimming pool is a complicated, technical project, and competent local engineers must always be involved.

Types of Waterfront

Types of waterfronts include natural lakes and ponds, streams and rivers, tidewater and other great bodies of water, man-made lakes and pools. (See Figs. 2 to 4.)

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

Fig. 2 Typical cross section of earth-fill dam.

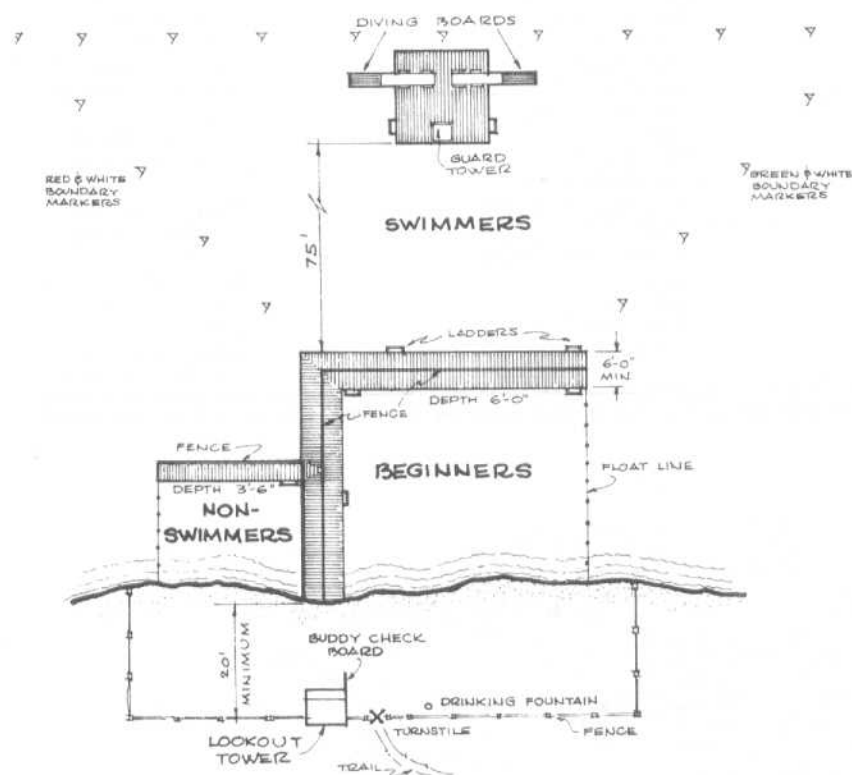

Fig. 3 Typical waterfront layout.

Natural Lakes and Ponds A fair-sized lake with clear and unpolluted water offers an ideal setting for development of camp aquatics facilities. Here are some of the important considerations:

- Control the whole shoreline. When the lake lies within the camp property, privacy is assured. A lake having cottages and other developments along its shores presents problems in privacy and protection.

- Control the watershed. This is a positive measure of protection against pollution. If the watershed is not owned, ask the assistance of local health authorities in making a survey of possible sources of pollution and in bringing about their elimination.

- The ideal size for a lake lies within broad limits. Thus, 15 to 20 acres might be a desirable minimum, while a desirable maximum would be 100 to 300 acres if three or four camps are to be built. Very small bodies of water are more easily polluted and are often subject to heavy weed and alga growth. On very

large lakes, it is more difficult to control the aquatics activities, and the program will often be interrupted by adverse weather conditions.

- Natural beach areas are an asset. Look for a gradually sloping bottom, preferably sandy, having a grade of 8 to 10 percent. A maximum depth of about 12 ft at a distance of 150 ft from shore is ideal. Submerged stumps, rocks, a muddy bottom, or steep slopes will require considerable work to make the area suitable for swimming.

- A nearly constant water level through the summer makes it simpler to install and maintain the various waterfront structures.

Streams and Rivers Suitable waterfronts can seldom be installed on streams or rivers, although they may offer excellent program potential for canoeing, boating, and fishing. Disadvantages, which can seldom be overcome, include flood danger and fluctuating water levels that may interrupt the daily program, strong currents that make swimming unsafe, difficulty of instal-

ling and maintaining waterfront structures, and high incidence of pollution.

Tidewater and Other Great Bodies of Water While great bodies of water offer many recreational opportunities, they are seldom well suited to the camp aquatics program. For example, tide action interferes with regular scheduling and makes instruction difficult, storms and high waves may interrupt the program for long periods of time, and waterfront structures are costly to build and maintain.

Camps located at or near tidewater should take advantage of the program possibilities offered, but should provide a pool or other body of water for instructional swimming.

Man-made Lakes Many councils have built lakes; and, when good design and construction procedures were followed, excellent results have been obtained. Even though the lake may not be suitable for swimming due to pollution or other factors, it provides for boating, canoeing, fishing, and nature study.

Selection of the site and design of the dam are not jobs for amateurs, and the best available engineer should be employed. The U.S. Soil Conservation Service has had wide experience in the design of small lakes, and their advice and help should be sought. Sound engineering experience is needed to determine the quantity and quality of water available; size of lake (consistent with the watershed and amount of water available); selection of dam site (with studies of subsoil); and type of construction for dam, spillway and other structures.

Preparation of the drawings and supervision of construction of the dam and other structures must be under the direction of the engineer.

The following are important considerations in design and construction:

- Avoid large areas of shallow water. The water tends to become warm and promote weed and alga growth.

- Provide for draining the lake. Maintenance of the beaches and waterfront structures and removal of silt will be greatly simplified. Lowering the water level in the winter may help control weeds and leeches and permit silt to wash off the beaches.

- Control silting. An upstream conservation program and silting basins may be needed.

- Grade and construct beach areas before filling the lake.

- Remove all trees and brush from the lake bed. Trees should be cut close to the ground and all debris removed. Topsoil need not be removed.

- Where flat slopes exist at the shoreline, make a vertical cut so that water will be 1 to 2 ft deep. This will minimize the growth of water plants and the breeding of mosquitoes. (This does not apply to beach areas.)

Recreation and Entertainment CAMPS AND CAMP FACILITIES

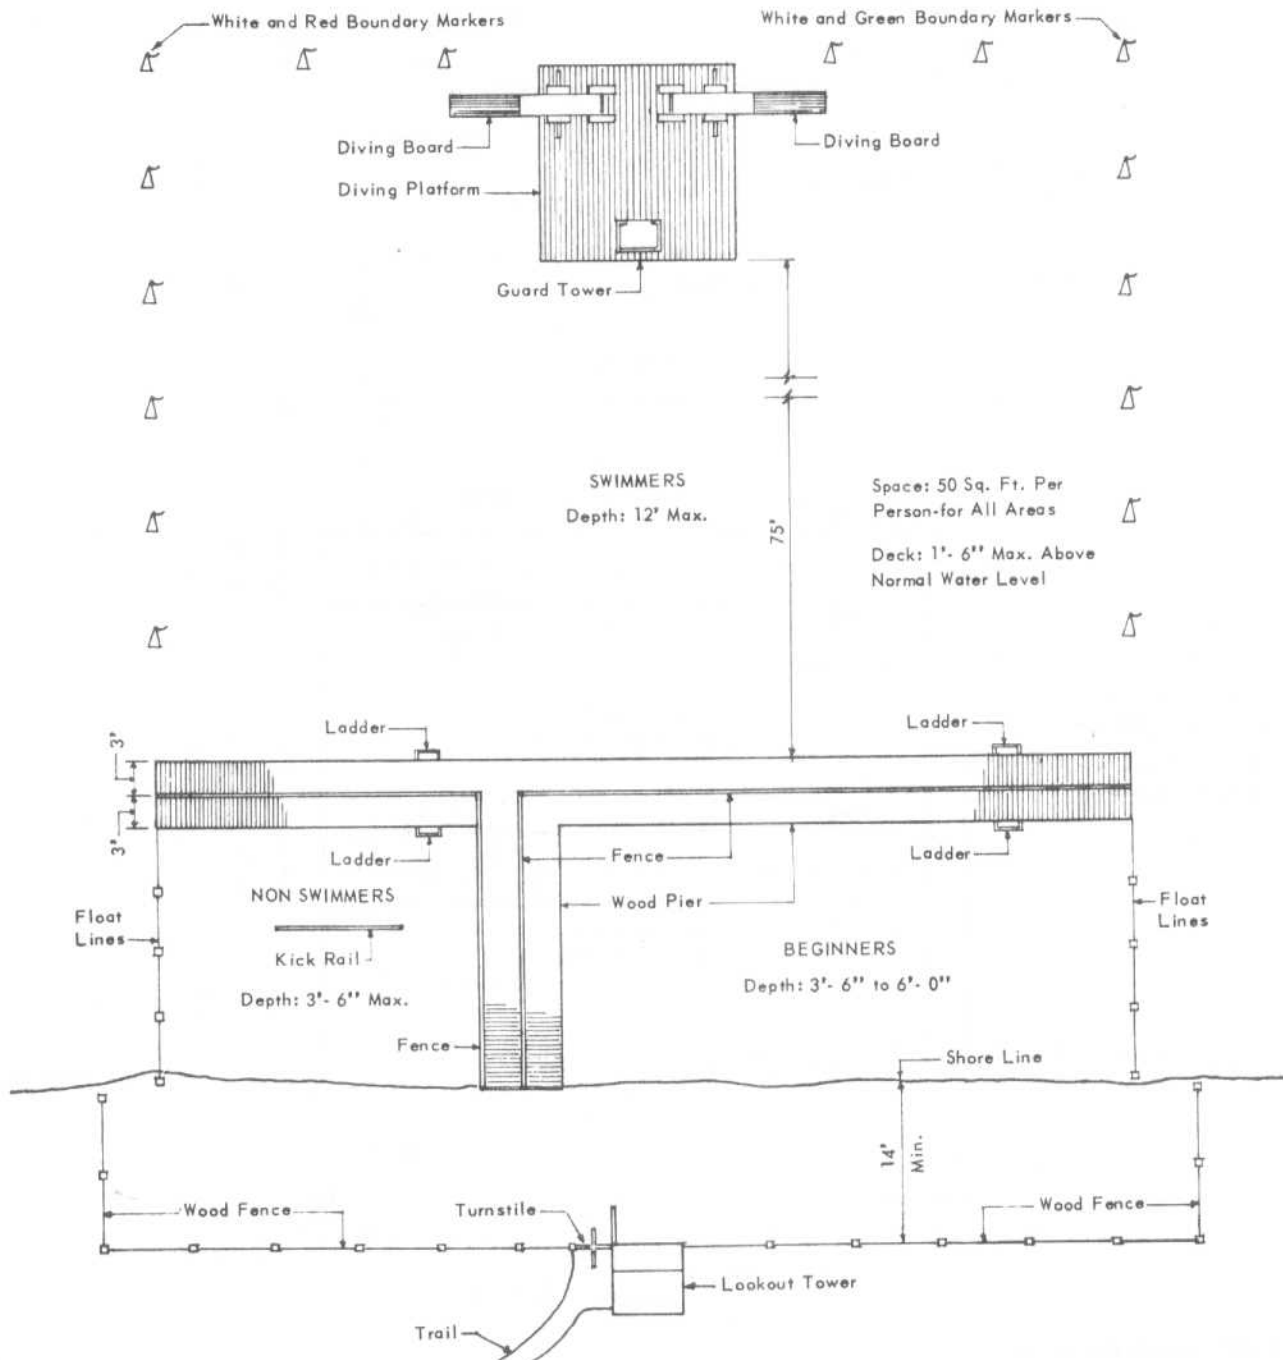

Fig. 4 Typical waterfront layout.

• Provide adequate depth. Twelve feet is a good maximum depth for the swimming area. Greater depths in other parts of the lake tend to keep the water cooler and minimize alga and plant growth.

Waterfront Layout and Facilities

Each waterfront presents a different situation, requiring specific design of the layout and structures. Such factors as bottom slope, bottom conditions, water-level fluctuation, and winter conditions will determine the most practical layout and type of structure to be installed. Whatever the situation these basic design factors apply:

• There should be one waterfront for each camp. It need not accommodate all campers at one time, but may be designed for use of one-third to one-half of the troops at one time (about 100 boys).

• Layout should include three separate areas:

1. Nonswimmers—maximum depth, 3 ft 6 in.
2. Beginners—maximum depth, 6 ft
3. Swimmers—maximum depth, 12 ft

Piers The best type of pier for the particular site depends on such factors as bottom conditions, water-level fluctuation, winter conditions, and such local considerations as the availability of materials and equipment. General types of piers include:

• **Fixed Piers** These are built to stay permanently in place and may be supported on pilings, frames, or cribs. They are most practical where ice is not destructive and where equipment is available for their construction. In a man-made lake, the pier supports may be installed before the water level is raised.

• **Removable Pier with Fixed Foundations** Where ice conditions are destructive to piers, it may be possible to install fixed supports extending within 1 or 2 ft of the water surface with deck sections attached in such a way that they may be removed in the fall.

• **Removable Piers** Prefabricated removable piers are commonly used at sites where winter conditions make fixed piers impractical.

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

Fig. 4 (cont.) Typical waterfront layout.

These are constructed of steel or aluminum with decks of the same material or of wood. They are adjustable within limits to varying water levels. Installation and removal of these piers entail considerable work. Annual maintenance is needed (Fig. 5).

• **Floating Piers** When fluctuating water levels make it impractical to install rigid piers, floating piers may be provided. They offer such disadvantages as unsteadiness, anchorage problems, and maintenance difficulties but are practical when properly designed and installed. The flotation equipment may be steel drums or styrofoam (with wood decks), or each section may be a metal or wood air chamber. Floating aluminum piers are available from some suppliers (Fig. 6).

Anchorage may be by cable or by vertical struts passing through sleeves attached to the sections.

Watch for the following when building piers:

- **Required Widths** The minimum width of fixed piers should be 6 ft, except for special conditions as shown on the accompanying layouts. Floating piers should have a minimum width of 8 ft.

- **Design Factors** Removable and floating piers should be designed in sections to permit easy handling on shore. Connections between sections should be sturdy and easy to secure. Piers carry heavy live loads, and supporting members must be sized accordingly. An engineer should design and supervise construction of all piers.

Floats and Diving Platforms A platform or float is commonly installed at the outside limit of the swimmers' area. If diving boards are to be provided, they should be placed on a solid platform, not on a float. Diving boards should not be higher than 1 meter above the water and a maximum of two (one at each end) may be installed on one platform. A raised lifeguard platform should be installed on all floats or platforms.

Design and construction of platforms and floats are based on the same general factors outlined for piers.

Beach The beach area adjacent to the waterfront should be fenced, with a turnstile or gate providing a single entrance. If the beach is of

Recreation and Entertainment CAMPS AND CAMP FACILITIES

Fig. 4 (cont.) Typical waterfront layout.

sand, its slope should not exceed 3 percent or the sand will wash away rapidly. It may be necessary to build a retaining wall and diversion ditches at the back edge of the beach to maintain the proper slope and avoid excessive erosion. The beach area may be sodded, in which case a low wall is required at the water's edge.

Lookout Tower The lookout towers should be placed where the lifeguard can see every part of the swimming area without turning his head. It is usually located at least 25 ft back from the

water and halfway between the side limit markers. The tower must be high enough to allow the guard to see over all waterfront equipment and should have a roof or awning to shade his eyes and head from the sun. The base of the tower may be enclosed to provide storage for equipment.

Layout for Boating and Canoeing Boat and canoe docking and landing areas should be separate from swimming area. There may be administrative advantages in having the two areas reasonably close together. However, the boat and

canoe area should be at least 200 ft from the swimming area (Figs. 7 and 8).

A boat pier or docking facilities should be installed. Several kinds are suitable. The type and design will depend on local conditions.

Canoes are beached and racked in the shade. Canoe racks should be low so boys can use them. Provision should be made for locking up paddles and oars when not being used.

Swim Cribs When no shallow water is available for instructional swimming, it is sometimes feasible to build a crib. This is constructed of

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

Fig. 4 (cont.) Typical waterfront layout.

wood supported on piles or rock foundations; or it may float. The depth of water in the crib should not exceed 3 ft 6 in. and a walkway and fence should extend around all sides.

Cribs are costly to build and maintain, and it is usually more practical to provide shallow water through some other means.

Swimming Pools

With increased public emphasis on health and safety, the "old swimming hole" is becoming a thing of the past. Regulations governing bathing places are in effect in most areas, and

many bodies of water have been closed to swimmers. The swimming pool has replaced them for both public and private use. In areas where a lake with clear, clean water and a sandy beach is not available, the swimming pool is certainly the best alternative. Pools offer additional advantages such as easy control, assurance of pure water, and freedom from environmental interference.

Design and Layout The term *swimming pool* here refers to a pool constructed of impervious materials with the water fully recirculated and treated through filtration and chemicals.

This is known as a *recirculating swimming pool* and must be considered standard for Boy Scout camp installations. The *fill and draw* pool can seldom meet health standards and should not be installed. The *flow-through* pool requires a large continuous flow of diluting water that must meet purity standards. Such pools are not recommended.

The design and construction of a swimming pool is a complicated technical project, and competent local people should be employed to do the job. (See Fig. 9.)

The functional layout should allow for program requirements, safety, traffic flow, con-

Recreation and Entertainment CAMPS AND CAMP FACILITIES

Fig. 5 Typical details of removable pier with fixed foundation.

venience of services, and economical use of construction materials and equipment. The following elements need to be included in the swimming pool layout and design:

- **Fence** The pool should be surrounded by a fence that will fully control access to the pool both during camp operation and year round. The one entrance for swimmers should be through a gate at the shallow end of the pool.
- Local conditions such as temperature, winds, and protection problems will determine the type of fence necessary. Provision should be made for spectators to see through the fence on at least one side of the pool.
- **Dressing Room and Showers** Toilets should be convenient to dressing room. Boys take a hot, cleansing shower and enter the pool

enclosure at the shallow end. The shower and dressing facilities should be situated far enough back from the gate to avoid crowding groups waiting to check in while others are checking out. The minimum distance is 15 ft. Double dressing and shower areas are desirable as they decrease congestion and permit more flexibility in use of the pool.

- **Walkway** A wide walk around the pool, sloped away from the pool edge, is required for instruction. The paved area reduces congestion when boys leave at the end of a swim period. The minimum widths are 12 ft at the ends and 8 ft along the sides of the pool. Concrete walkways must be finished with a lightly brushed surface to afford firm footing. *Non-swimmers, Beginners, and Swimmers* should

be clearly lettered at appropriate points on the edge of the pool.

- **Nonswimmers Area** The water should not be over 3 1/2 ft deep in this area. (Depths: 3 ft sloping to 3 ft 6 in.)

- **Beginners Area** This area should combine both shallow water and water slightly over the head of the Scout. (Depths: 3 ft 6 in. sloping to 6 ft.)

- **Swimmers Area** The remainder of the pool is for the use of more advanced swimmers. The diving board should not exceed 1 meter in height above the water, and should be located at the center of the deep end. Water depths will vary from 6 to 9 ft. Minimum depth at 7 ft beyond the diving board should be 9 ft.

- **Lookout Tower** A lookout tower should be installed. It should be high enough and so placed that the lookout can see the entire swimming area without turning his head. A roof or awning should be provided for shade.

- **Overflow Gutters** Overflow gutters must extend around the whole perimeter of the pool and must be designed in accordance with the latest standards.

- **Sidewalls** Pool sidewalls must be vertical where water is less than 6 ft deep. Sloping and curved sidewalls are dangerous and difficult to clean. Stairwells, if installed, should recess into the pool wall.

Size and Shape The size of pool for a typical camp is determined by these factors:

- Not more than four average-sized troops should use the pool at one time (60 to 65 boys).
- Since most boys are in the water throughout the swim period, allow 40 sq ft per person. Minimum pool area would therefore be about 2,600 sq ft.
- Seventy-five feet is a standard pool length, so the minimum rectangular pool would be 75 by 35 ft for a 10- to 14-troop camp.

Pools have been built in many shapes to meet special conditions. For Boy Scout camps, however, two shapes have proved to be most practical from the standpoint of use, original cost, and operating and maintenance costs. These are:

- Rectangular pool, 75 by 35 ft.

Fig. 6 Typical details of floating pier.

CAMPS AND CAMP FACILITIES

* Fan-shaped pool 30 ft wide at the deep end, 50 ft wide at the shallow end, and 75 ft long. This pool is only slightly larger in volume than the comparable rectangular pool, but provides considerably more shallow water. This is an important factor where the proportion of nonswimmers and beginners is large.

L-shaped pools or other variations may be entirely satisfactory when properly designed but are generally more costly than the rectangular or fan-shaped pools.

Pools smaller than 30 by 60 ft cannot adequately meet program requirements.

Site Selection The pool should be situated near the central features of the camp and approximately equidistant from the troop sites. It is best to lay out the pool on a slope with the deep end on the lower grade. This saves excavation and provides an opportunity to construct the pump room adjoining the deep end with the sidewalk above. The pool *should not* be placed in a hole.

The top grade of the pool walks should be established so that excavation will balance fill, thus saving costs and keeping the pool surface as high as possible. With the pool walls and sidewalk built above surrounding grades, there will be no likelihood of surface water getting in to contaminate the pool water. Also, ground-water and frost problems will be reduced.

Do not locate the pool under trees as leaves and bark dropping in the water will place an added burden on the filter system and may cause a stoppage in the drains.

Whenever possible, avoid facing the lookout tower or diving board toward the south or west.

Materials and Construction Features There are several types of materials used in pool construction. Experience in Boy Scout camps leads to the following conclusions about types of material:

• **Reinforced Poured Concrete** This is the most widely used and accepted material for constructing pools in Scout camps. It is long-lasting and the construction procedures and methods used are well known and can be readily supervised and inspected. This method avoids many of the variables inherent in use of other materials and has a long record of satisfactory service under varying conditions.

- **Metal** Both steel and aluminum pools have been installed and have given satisfactory service. Special consideration must be given to rust and corrosion.

* "Gunite" These pools have been built in great numbers, particularly for residential and other specialized uses. There are problems inherent in their design and construction that make it difficult to meet such standards as vertical sidewalls and smooth surfaces. Maintenance problems are more frequent than with other pools.

Whatever type of pool is installed, the bottom and sides must be white or light-colored and have a smooth-finish surface without cracks.

Water Supply and Treatment The recirculating pool does not require a large daily supply of water. Once filled, only 5 to 10 percent of the volume needs to be replaced daily, depending on frequency of backwashing the filters and other loss factors.

The pool water is continuously circulated by pumps through the filter system and purified by treatment with chlorine or other disinfectants. Recirculation accomplishes the dual job of removing suspended matter in the water by the straining action of the filter medium and other strainers and distributing disinfectant and other chemicals through the water to maintain proper residuals throughout.

Fig. 7 Typical boat tie-up.

Fig. 8 Typical canoe rack.

Recreation and Entertainment
CAMPS AND CAMP FACILITIES

Fig. 9 Standard camp pool.

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

The recirculation and treatment equipment must be capable of turning over the whole pool-water volume in the period of time required by state and local ordinances—usually 8 hours. Return water inlets must be so located that there are no "dead spots" of un-circulated water in the pool.

• **Filters** There are two types of filters commonly used in pool systems: sand and gravel, and diatomaceous earth.

1. Sand and gravel filters are used extensively and have proved to be most satisfactory. They may be either of the pressure or the gravity type. The pressure type is more common, but the gravity type is preferred by many as being simpler to operate and maintain.

Because of their simplicity of operation and economy and ease of maintenance, sand and gravel filters are usually preferred for camp installations.

2. Diatomaceous earth filters are often used and offer some advantages. They may be either the pressure or vacuum types. Filters employing diatomaceous earth as a filter medium demand a more exacting operation and have caused problems in camp installations.

• **Disinfectants** Chlorine is the most commonly used disinfectant for water treatment. It not only disinfects the water as it is recirculated, but makes possible the maintenance of a residual to combat contamination as it is introduced. Chlorine may be applied as a solution of chlorine gas in water or as a hypochlorite solution. Other methods of disinfecting pool water are in limited use, but should be considered experimental at this time.

• **Suction Cleaner** Provision for a suction cleaner should be made. This is the most satisfactory method of removing dirt and other debris from the pool bottom.

SHOWER FOR POOL AND CAMP

The facilities described here are designed to serve as a pool shower, but will also serve as the central camp shower and laundry. The shower is designed for a 10- to 14-troop camp.

Functions

The functions of the shower building are to:

- Provide hot, soapy showers for all persons entering the pool
- Provide hot showers for campers anytime
- Provide minimum laundry facilities for campers and staff
- Provide storage space for first aid supplies and small equipment

Location

Shower is located at the shallow end of the pool at least 15 ft back from the pool fence. It should be on a level site, open to the sun, and with adequate space for sewage disposal.

Space Requirements

Dressing Rooms Two at about 200 sq ft each are needed.

Shower Rooms Two at about 150 sq ft each are needed.

Heater Room, Storeroom, Toilets, Laundry Totals about 400 sq ft.

Waiting Deck Provide at least 15 ft between pool fence and building; area is about 500 sq ft.

Requirement Checklist

Water Total daily demand varies but average maximum would be about 2,400 gal. Peak demand is about 50 gpm.

Hot Water A gas-fired, coil-type heater with about 100,000 Btu input and about 100 gal per hour 100° temperature rise will provide the needed hot water. Vent heater to outside and install 500-gal, insulated storage tank. Install a temperature-control valve to limit water temperature in showers to a maximum of 110°.

Sewage Disposal Disposal method depends on local conditions and ordinances. Sewage totals about 2,400 gpd. The total may be treated by installation of a 2,400-gal septic tank and disposal field. If permitted, wastes from the showers and laundry may be treated separately from those from the toilets, urinals, and lavatories. In this case, a 1,000-gal grease trap would handle the shower and laundry wastes and a 750-gal septic tank would handle the balance. Effluents would be combined and piped to the disposal field.

Light and Power Moistureproof fixtures are required. Provide outside fixtures at entrances.

Ventilation Good natural ventilation is very important. Only the storage and heater rooms should be fully enclosed, and these should be well ventilated. Dressing rooms need no roof, and shower rooms should be open to allow the sun to dry floor and walls.

Floors Concrete should have smooth finish. Provide curbs around shower room and pitch floor to drain. Also pitch dressing-room floors to drain.

Walls Install waterproof walls in shower rooms. Leave vertical space between all walls and floor to avoid rot. Walls in toilet and laundry areas should have a smooth finish for easy cleaning.

Access and Layout Provide baffled access to dressing rooms and doors with locks to storage and heater rooms. Lay out building so that camper access to the pool must be through the dressing room, the shower, and the waiting deck. Entrance to the pool is through a single gate at the shallow end.

Equipment Provision should be made for the following:

• **Dressing Rooms** Each should have benches, shelves, and hooks. There should be a toilet, urinal, and two washbasins with each dressing room.

• **Shower Rooms** Each has six to eight shower heads with individual hot and cold valves.

• **Heater Room** This contains water-heating equipment only.

• **Storage Room** Provide first aid cabinet, shelves, and hooks for equipment. If room is used as office for waterfront director, provide table and chair and install window facing pool.

• **Laundry** This room should have two laundry tubs with drainboards.

RIFLERY

All Scout camp rifle ranges and range operating practices must be certified by the Health and Safety Service of the National Council, Boy Scouts of America.

When a range site is to be selected, each

property presents a different problem. A wrong selection may lead to costly construction, poor range operating conditions, or a hazard to campers or neighbors.

The range is usually located on the outskirts of camp, away from troop sites and other heavily used areas. It should be designed for use of .22 caliber rimfire rifles only. There should be 50 ft from the firing point to the face of the targets. (See Fig. 10.)

A 5- to 10-point range is adequate for the standard camp of 10 to 14 troops. Under some conditions, a larger range may be built to serve two camps at a multiple-camp reservation.

Direction of Fire A northerly direction of fire is preferred since it permits firing at any time of day without the sun shining into the eyes of the shooters or the range officer.

Backstops The purpose of the backstop is to catch and hold all bullets. It must not contain any material that will cause ricochet. Backstops may be constructed to utilize a natural slope or they may be built on level ground (Fig. 11).

• **Hillside** A hillside that extends at least 30 ft higher than the firing point may be used. The slope must be cleared of brush to a height of 30 ft above the targets and 60 ft beyond the flanks of the target frames. Rocks must be removed or covered and a sod cover maintained to avoid ricochets. Since the firing line and target butts must be at equal elevations, it is usually necessary to excavate and grade the range site. If the exposed cut is free of rock and stones, it will make a suitable backstop.

• **Earth Embankments** When a suitable hillside is not available, an excellent backstop can be constructed of earth fill. It should be at least 10 ft high and 3 ft thick at the top with allowance for settlement. The earth must be free of stones. The embankment should extend beyond the target butts at each end, these extensions being placed as "wings" to cut off any stray bullet to the side. The embankment should be planted with grass and a sod cover maintained.

• **Earth and Timber** When suitable earth for an embankment is not available, the backstop may be constructed of heavy timber backed with sand or earth. The crib must be at least 10 ft high with wing walls. If an extra plank is added directly behind each target and so attached that it can be easily replaced, the timbers in the main structure will not need constant replacement.

Open Country In open, flat country where visibility extends for at least 3,000 ft beyond the targets and where there are no roads, trails, or grazing animals, open target butts may be used without a backstop. A body of water, navigable by canoe or larger craft, may not be used as a backstop.

Safety and Fencing Even though a suitable backstop is constructed, the range may be hazardous unless it is properly fenced and warning signs displayed. The area from the backstop to the ready line should be fenced and only one entrance provided to the area behind the firing line. Rail fencing is suitable for this purpose.

Any "blind" approaches to the range should be fenced and warning signs erected.

It is particularly important to protect areas behind the backstop.

Target Butts Targets should not be attached directly to the backstop. Erect posts and construct a frame to hold targets at the proper

Recreation and Entertainment CAMPS AND CAMP FACILITIES

Fig. 10 Typical rifle range.

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

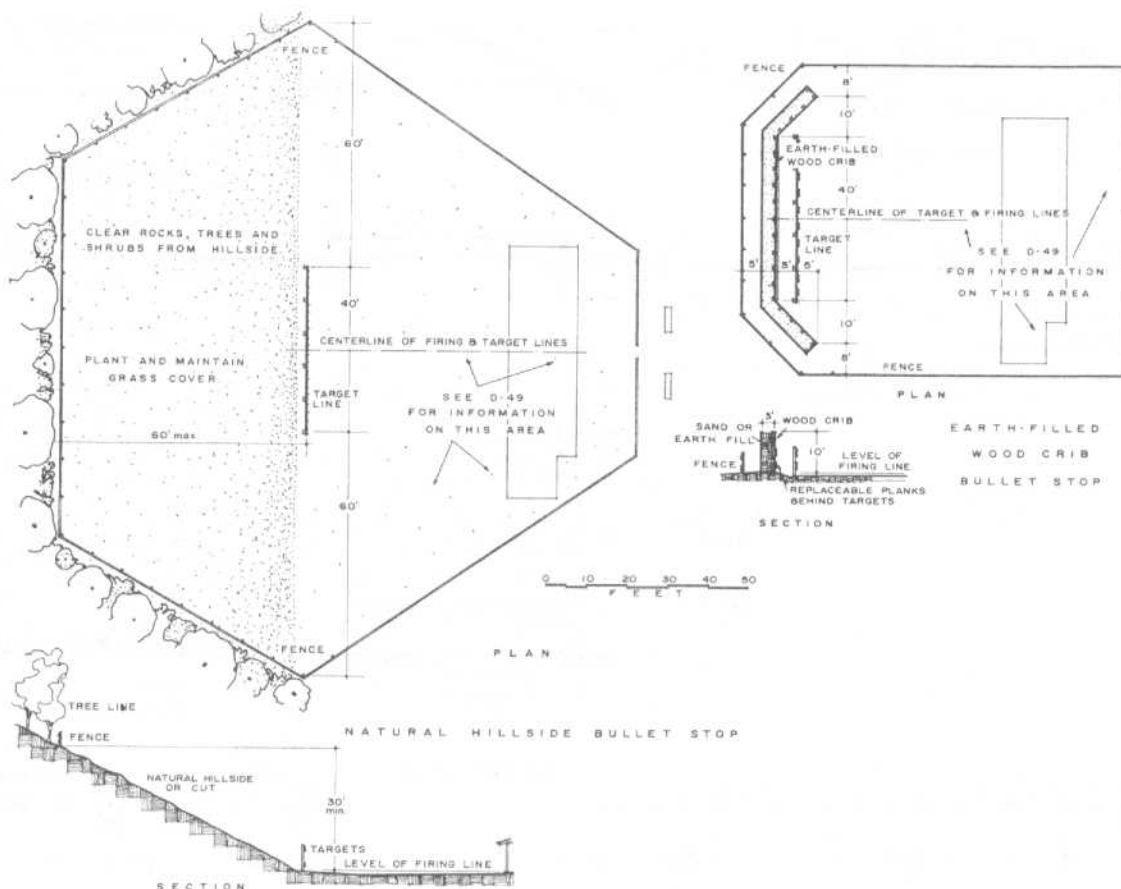

Fig. 11 Rifle range—bullet stops.

levels for prone and offhand shooting. The frames should be set 50 ft from the firing line and will need replacement periodically.

In those areas where target practice is considered to be essential to the program, every possible effort should be made to safeguard not only the shooters but others as well. If the facility is not properly designed, and the program properly conducted under the strictest regulations, this can be a very dangerous activity for any age group.

A well isolated area, with a high earthen backstop (side banks, too, if possible) should be selected. The entire area given over to this activity should be well fenced with access gained through one controlled gate. All standing vegetation should be kept cleared for at least 100 yd in back of the butts.

Firing Line The firing line should be level from end to end and well drained. A minimum of 5 ft is required between firing points. The area between firing line and the targets should be graded, drained, and have a well-maintained sod cover.

It is desirable to provide shelter over the firing line. A frame-and-canvas shelter may be constructed or a permanent shelter with a wood or concrete floor installed.

Ready Line The fence and ready line should be installed 20 ft back of the firing-line shelter. Benches should be installed for those waiting to shoot and for spectators.

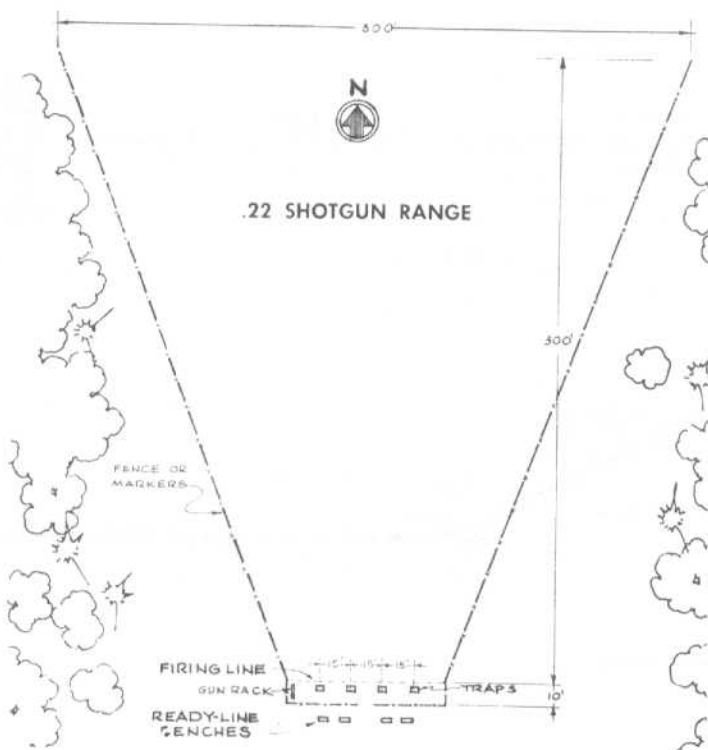

Fig. 12 .22 shotgun range.

Recreation and Entertainment

CAMPS AND CAMP FACILITIES

Storage of Equipment All rifles and ammunition must be kept in locked storage when not in use on the range.

.22 Caliber Shotgun

The .22 caliber shotgun range is usually located on the outskirts of camp away from troop sites and heavily used areas. A large field makes an ideal site. The area to be protected extends 300 ft in front of the firing line, fanning out from the ends of the firing line to a width of 300 ft. The area should be cleared of brush.

The range is designed for .22 caliber smooth-bore shotguns using .22 caliber shot ammunition. A four-trap range is adequate for a camp serving 10 to 14 troops (Fig. 12).

Storage of Equipment All guns and ammunition must be kept in locked storage when not in use on the range.

ARCHERY

The archery range may be located at any point in the camp where there is sufficient open area and reasonably level ground not crossed by trails. An open field is ideal. (See Fig. 13.)

An area about 150 by 250 ft will suffice for a six-target, 50-yd range adequate for a 10- to 14-troop camp. Rocks should be removed or covered to avoid breaking arrows. A sod cover is desirable. The range should be laid out so that shooters face in a northerly direction.

The range should be roped off or fenced and warning signs erected.

CAMPFIRE AREAS

The campfire is a traditional camp activity that combines fun, fellowship, and inspiration. Troop and campwide campfires are held one or more times each week. (See Figs. 14 and 15.)

WATERFRONT STORAGE BUILDING

Functions

The purpose of the waterfront storage building is to provide safe storage for boats, canoes, piers, and other waterfront equipment. It should not be used as living quarters for the waterfront staff.

Space Requirements

This will vary depending on the number of boats and canoes to be stored. A room 23 by 35 ft will store 12 canoes and 12 rowboats racked three high and will allow aisle space for moving boats in and out.

Design the building for expansion. Work space for boat repair is sometimes provided in one end of the building (Fig. 16).

CENTRAL LODGE—6-8 TROOPS—SINGLE CAMP

The central lodge is used in camps where several troops eat in one dining facility.

Function

The central lodge is used for the following purposes:

- Receiving, storage, refrigeration, and handling of food for about 125 people.
- Family-style service of meals to about 125 people at tables seating 8 each. (160 people may be seated 10 at a table for occasional meals.)

• Preparing meals for about 125 people. (Occasional meals may be served to 200 or more.)

• Commissary service for packaging and issuing raw foods to troops doing patrol cooking and to Scouts doing instructional or trail cooking. (This varies with program, but may average two troops per meal.)

• Occasional meetings or activities of large groups. (Dining hall may be used in rainy weather for some activities and religious services. Building may be used off-season for training, meetings, and other Scouting activities.)

Location

The lodge should be located in a central area convenient to troop sites. Select a good

building site that is well drained, reasonably level, with adequate space for sewage disposal. Site should have a pleasant outlook, but should not be closer than 300 to 400 ft from any body of water. Orient with regard to terrain, prevailing wind, and sun. A southern exposure is usually preferred. Consider relationship to parking area and other central facilities (Fig. 17).

Space Requirements

Typical requirements for the central lodge include the following:

Kitchen Wing There should be a total of about 1,600 sq ft, including 640 sq ft for food handling and preparation, 310 sq ft for serving and dishwashing, 400 sq ft for commissary and

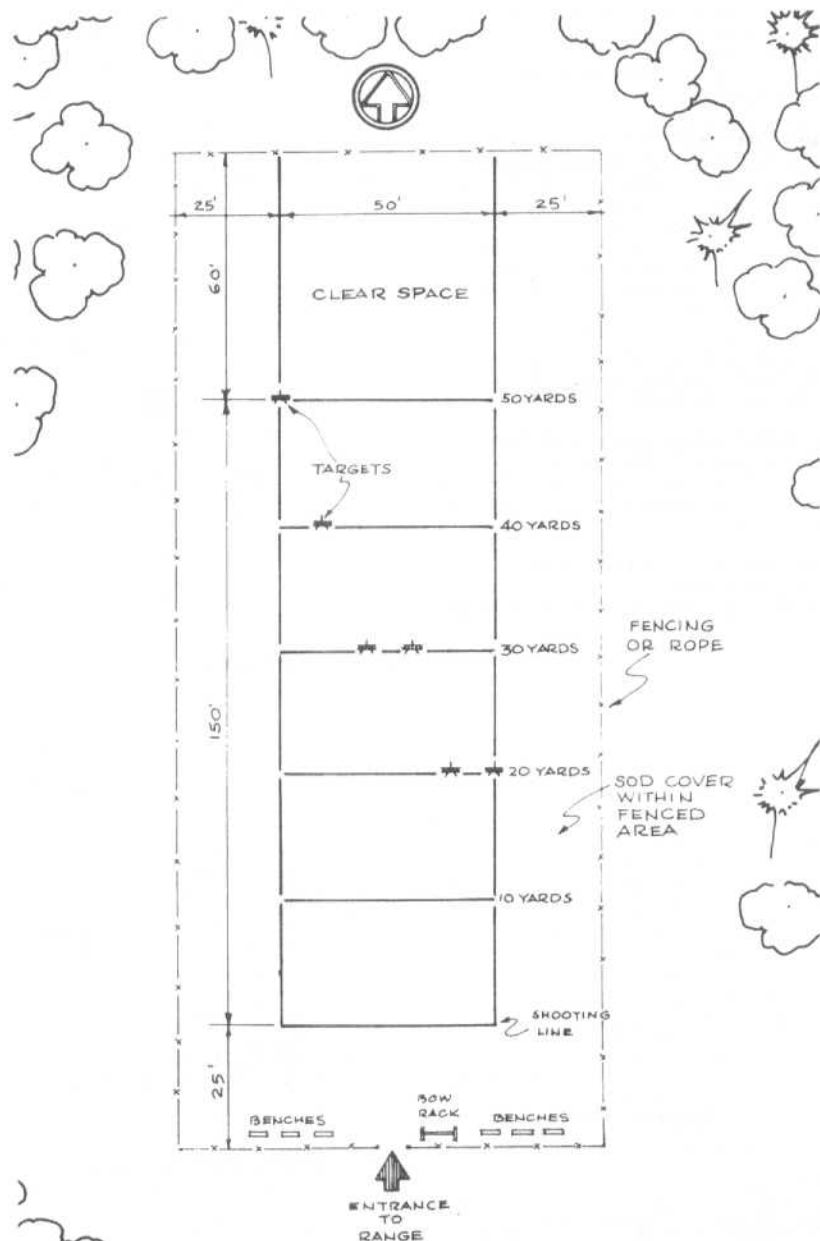

Fig. 13 Archery range.

CAMPS AND CAMP FACILITIES

issue porch, and 250 sq ft for storage and refrigeration. (Based on semiweekly delivery of staples and daily delivery of some perishables.) (Fig. 18)

Dining Hall About 2,000 sq ft is needed, including 1,280 sq ft for 16 tables (80 sq ft each, including seating and access space) and about 700 sq ft for aisles and circulation space, including space for setting up two more tables if necessary.

Porch This is a desirable addition in many areas. It requires an additional 850 sq ft.

Requirement Checklist

Water Daily demand (at 6 gal per person) is about 750 gal. Peak demand is about 22 gpm.

Hot Water Dishwashing (either by hand or using immersion-type dishwashing machine) and other kitchen needs require hot water. The heater should be an automatic, gas-fired, coil-type, having about 110,000 Btu rating and about 105 gal per hour 100° temperature rise. It should be vented.

Hot-Water Tank This should be galvanized, have 2-in. insulation and a 300-gal capacity.

NOTE: A sanitizing sink, for final rinse of dishes, must maintain a temperature of 180° or include an effective sanitizing agent. To establish and maintain the 180° temperature, an auxiliary heater will be required at the sink. Temperatures for dishwashing and other uses would be 110 to 120°.

Toilet Provide toilet and washbasin for cooks. Shower may be desirable. Access from cooking area to toilet must be through two doors.

Sewage Disposal Sewage totals about 750 gpd, usually requiring a 1,000-gal septic tank and disposal field. A grease trap will be effective for treating waste dishwater if soap (and not detergent) is used.

Light and Power Good illumination is required in all spaces. Power requirements vary with equipment used. Provide protected control panels.

Fig. 14 Plan of council ring.

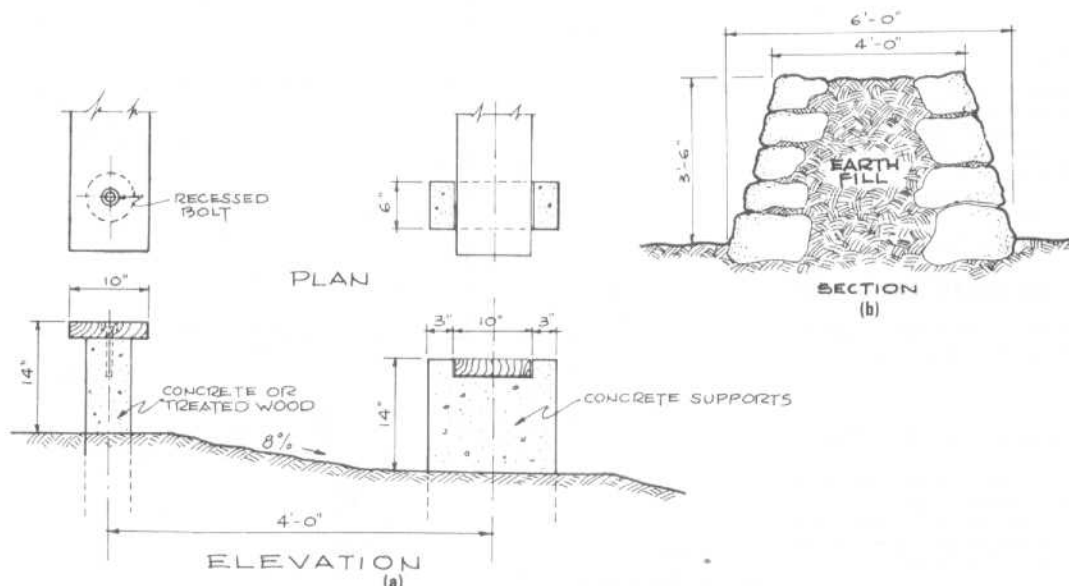

Fig. 15 (a) Two types of seat supports. (b) Fire platform.

Fig. 16 Waterfront storage building.

Refrigeration Walk-in box, having at least 64 sq ft of floor space and capable of holding a temperature of 36 to 38° is necessary. A two compartment walk-in may be installed with one compartment at 33 to 38° for meat and fowl and one compartment at 38 to 46° for other perishables.

The reach-in refrigerator should have about a 17-cu-ft capacity. A water cooler, deep freeze, and ice machine are sometimes desirable.

Heating Need will be determined by climate and use of building.

Ventilation This will also be determined by climate. Natural light and ventilation are desirable in all work and dining areas. Forced exhaust through the hood over the range is desirable for kitchen, and in some areas evaporative coolers are installed in kitchen. In most areas natural ventilation is adequate for dining hall; but large, slow-turning exhaust fans are effective and may be desirable.

Floors Smooth, impervious floors are required in all spaces. Smooth-finish concrete is most common. Provide adequate floor drains in kitchen.

Walls Interior walls of kitchen must be smooth, easily cleaned, and light color. Dining-hall walls may be unfinished.

Ceilings A ceiling may be required in kitchen area depending on type of building construction. The kitchen overhead must be clean and not a "dust-catcher." Dining halls usually have no ceiling, but the roof construction should provide a pleasing appearance.

Screening Kitchen wing and dining hall should be screened to exclude insects.

Access Provide an all-weather service road to delivery platforms at kitchen wing. Provide good walking paths to dining hall from tenting and program areas. Access trails from parking

area and administration facilities should lead to the front of the dining hall—not to the kitchen wing.

Equipment and Layout—Kitchen Wing The kitchen wing should provide for the following:

- **Range** Heavy-duty, gas-fired, all hot top, about 68 by 42 in., with two ovens, double-deck high shelf, and hood with grease filters and exhaust fan.

- **Sink for Vegetable Preparation** Stainless steel, 24 by 24 by 14 in. with drainboard at one end, mounted on metal legs.

- **Sinks for Pots and Pans** Stainless steel, two compartments 30 by 30 by 14 in. with drainboards at each end, mounted on metal legs.

- **Sinks for Dishwashing** Three, stainless steel, mounted in stainless-steel counters to provide space for scraping, stacking, washing, rinsing, sanitizing, and draining dishes. (Sinks should be 24 by 24 by 14 in. Provide 10-in. splash backs on sinks and counters adjacent

CAMPS AND CAMP FACILITIES

Fig. 17 Central lodge.

to wall, other edges should have raised, rolled rim. Provide overflow tubes on rinse and sanitizing sinks. Mount sinks and counters on metal legs. A three-compartment, immersion-type dishwashing machine may be substituted for the sinks. Machine should provide heating equipment to maintain required water temperature in each compartment.)

• **Mixer** Electric, table model, with 20-quart bowl, whip, and beaters.

• **Peeler** Electric, 15 lb per minute capacity.

• **Cook's Table with Utensil Rack** Maple top, about 30 by 96 in., with two stainless-steel drawers, mounted on metal legs. (Provide three-bar steel utensil rack over the table.)

• **Baker's Table** Maple top, about 30 by 72 in., with 6-in. curb at back and ends, mounted on metal legs. (Provide tier of three stainless-steel, watertight drawers and two stainless-steel, rounded-bottom tilting bins.)

• **Serving Counter** Stainless-steel, 30 in. wide, with lift-up section.

• **Clean-Dish Storage** Below serving counter. (Provide two shelves enclosed with dustproof and flytight doors, accessible from both sides; cupboards and shelving for dustproof and flytight storage of serving dishes, silver, and condiments.)

• **Pot-and-Pan Storage** Shelving under tables and work counters.

• **Wheeled Carts and Racks** Desirable for moving cartons, dirty dishes, or storing pots and pans.

• **Dry Storage** Rodentproof room for dry storage of foods, with shelf and floor space arranged for cartons and broken lots. (Space depends on frequency of deliveries.)

• **Commissary** Shelving, worktables, and counters for sorting, packaging, and setting out packaged foods for issue to patrols or individual Scouts. (Furnish desk or table for commissary man. Provide ready access to refrigeration and dry storage and to the outside. Porch is desirable at pickup counter.)

• **Traffic Flow** Provide for the following in kitchen wing:

1. Efficient flow from unloading platform to storage and refrigeration, to food preparation, and to serving counter
2. Efficient flow from soiled-dish-receiving counter to dishwashing—to clean dish storage—to dining hall
3. "In" and "out" doors from dining hall to serving counter with adequate space for circulation
4. Closing doors or shutters for all openings between kitchen and dining hall to control noise
5. Work aisles 42 in. wide between range and cook's table and between cook's table and serving counter
6. Separation of dishwashing area from food preparation area by means of counter or wall
7. Adequate counter space for return of most dirty dishes at one time

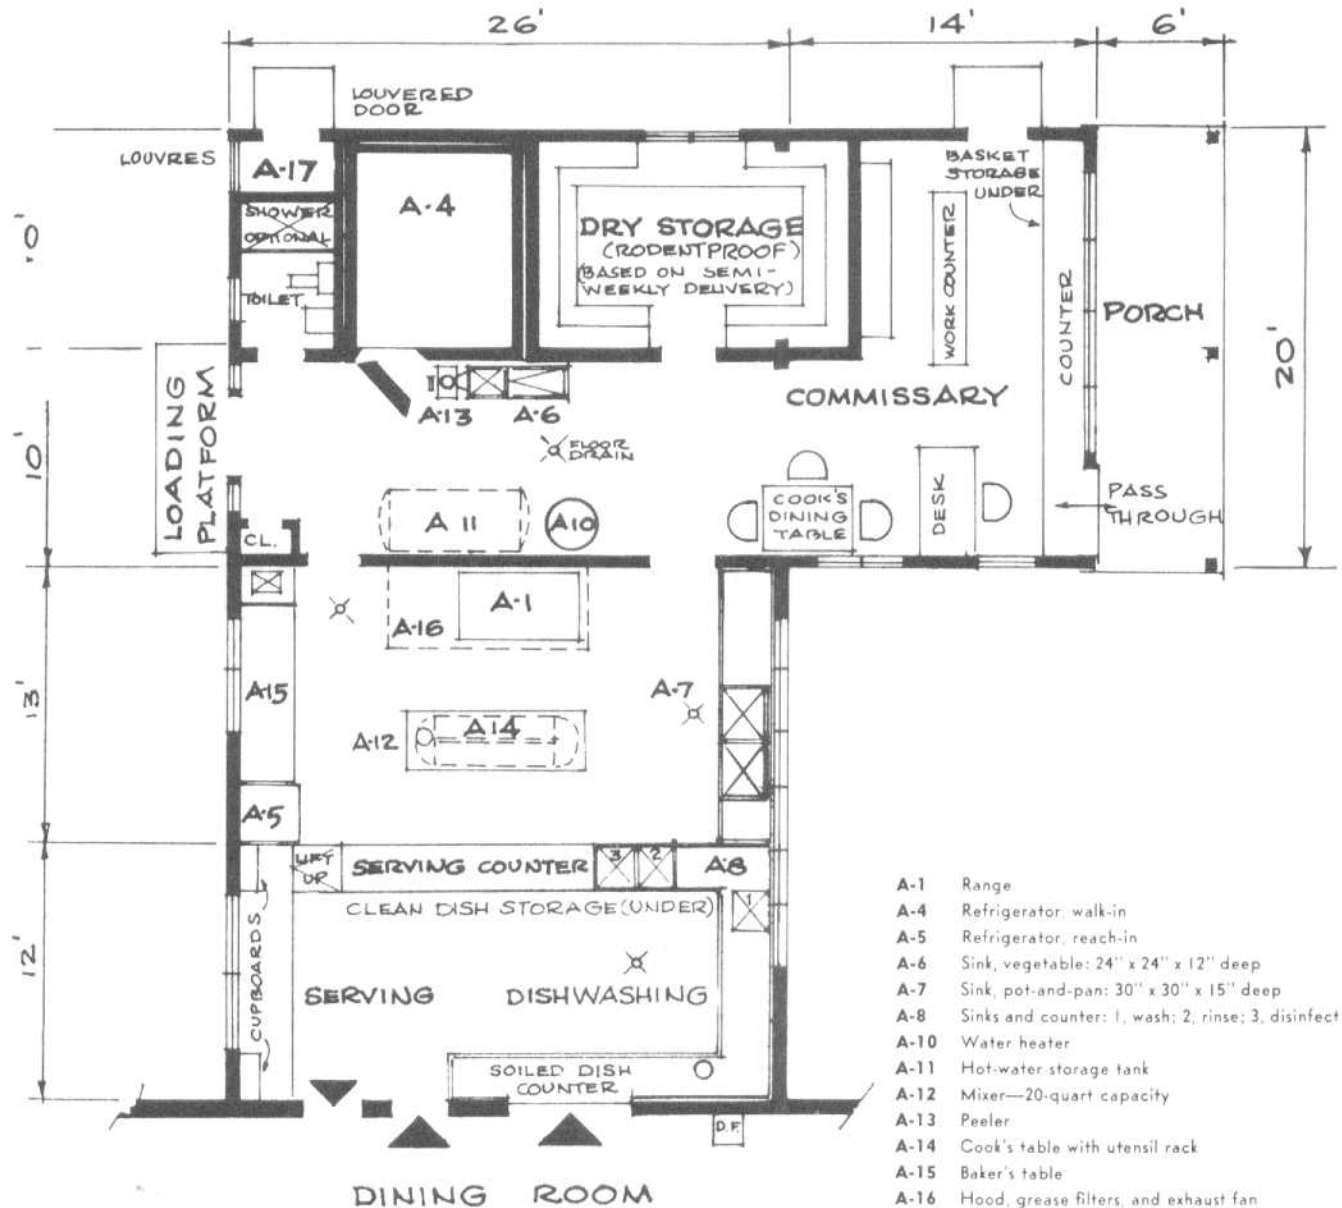

Fig. 18 Kitchen wing for central lodge. Six to eight troops, single camp.

Equipment and Layout—Dining Hall The dining hall should provide for the following:

- **Tables** Smooth top, with impervious surface without cracks or raised edges 4 by 6 ft, each to seat eight for family-style dining. (Folding tables are desirable if dining hall is to be used for other activities.)
- **Chairs or Benches** Either are suitable.

(Folding chairs are desirable if dining hall is to be used for other activities.)

- **Fireplace** Desirable for atmosphere, but not effective for heating whole area.
- **Drinking Fountains** Desirable. (Provide also for supplying table water.)
- **Traffic Flow** Arrange for the following in dining hall:
 1. Wide doors (opening out) on at least

three sides of dining hall for easy movement of campers

2. Four-foot clear aisles for waiter traffic from each table to serving and soiled-dish counters
3. Ample open area (at least 10 ft) around serving doors and soiled-dish counter
4. Clear aisles (at least 4 ft wide) to all outside doors

ZONE PLANNING

Zoning, as in Fig. 1, is a useful tool in planning new or remodeled farmsteads after the general site has been selected. Although 100-ft-wide zones are shown, wider ones are often desirable.

1a. Four planning zones.

If the road is busy, or if a tree windbreak is between the house and the road, set the house back further than 100'.

1b. Example: Livestock enterprise north of the road.

Major centers: living, livestock. Secondary centers: machinery, grain. One driveway serves all centers; a separate drive could serve a new large livestock unit. The living area can be screened from other areas, yet it is convenient for family use, visitors, and observation. Leave space near all areas for expansion.

1c. Example: Grain enterprise north of the road.

Major centers: living, grain. Locate machinery and supply areas for convenience and accessibility.

Fig. 1 Farmstead planning zones. Zones help the planner organize each activity relative to all other activities, and to allow for each planning factor for each activity. Each zone is 100 ft wide—less space may lead to crowding, and wider zones are often desirable. The areas of the zones as shown are: Zone 1 = 0.7 acre; Zone 2 = 1.6 acres; Zone 3 = 2.3 acres; Zone 4 = 2.8 acres. The first three zones include most basic buildings and equipment and use about 4.6 acres.

For a farmstead with a family living area, place the house at the center of the planning zones. For a farmstead without a house, the farm court is usually the center, because vehicles, materials, and labor tend to work from the court. These 100-ft bands are activity zones, and they help locate major activity areas, help preserve a desirable family living environment, and they encourage spreading the farmstead out, leaving space for present operations and future expansion. See Figs. 1 and 2.

Zone 1—Family Living Lawns, recreation space, flower and vegetable gardens, and guest parking are close to the house. Protect Zone 1 from noise, odor, and dust as much as possible.

Farmstead Planning Handbook, Midwest Plan Service, Iowa State University, Ames, Iowa, 1974.

Zone 2—Machinery Center Shop, storage, and related services that are relatively quiet, dry, and odorfree are in Zone 2. Consider screening the center from family view.

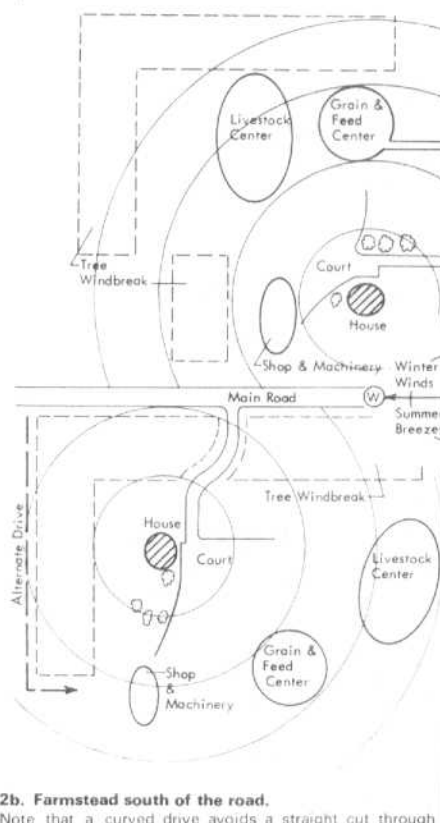

Much of the driveway and farm court may be in Zone 2. Put fuel and chemical storage toward the outer edge—near the machinery, but removing odors, fire danger, and some hazard to children perhaps 200 ft from the home.

Zone 3—Grain, Feed, and Some Livestock These areas cause dust, noise, traffic and odor, and are therefore moved another zone further from the house.

Grain and feed handling and processing require electric power and good vehicle access. But, keep heavy equipment, large dryers, and fire hazard away from the house. Zone 3 is a compromise. Small animal units may also be in Zone 3; that

2a. Farmstead west of the road.

Some winter winds come from the NW. Locate the house as far west, and the livestock area as far north, as practical.

2b. Farmstead south of the road.

Note that a curved drive avoids a straight cut through the windbreak. Moving the house further south and the livestock area NE is desirable. An alternate drive location makes a good layout if the house and machine center can be reversed.

2c. Farmstead north of the road.

A good relation between house, windbreak, livestock center and main road is easy with this layout.

2d. Farmstead east of the road.

As in 2c, good layout is easy, assuming drainage and other factors permit this arrangement.

Fig. 2 Farmstead and main road relationships. Only major activity centers are illustrated. Location within the farmstead area is also determined by many other factors, such as drainage, electric and water lines, sewage system, and topography.

FARMSTEADS

is, small animals or a small number of animals may not seriously degrade family living. A livestock unit close to the house is convenient for active management of maternity and nursery units or for care of pet or hobby animals.

Zone 4—Major Livestock Facilities A large unit, whether confined to a building or on drylot, creates demand for adequate space, drainage, waste management, access, loading facilities, feed distribution, and other services. It also creates noise, dust, traffic, and odors. Space for expansion is usually important. Locate major livestock production in Zone 4 or beyond.

Moving away from the old farmstead is frequently the most economical, as well as satisfactory, way to solve major expansion problems.

Zone planning applies to both cash grain and livestock farms. A grain farm can become a livestock farm and vice versa, so allow for both grain and livestock in your master design, to protect future growth, efficiency, and sale value. Adjusting to changes in health, labor supply, or economics can be difficult unless space is available for expanded and new facilities.

Farmstead and Main Road

The illustrations in Fig. 2 show some of the problems encountered in designing a farmstead plan. Prevailing winds are assumed from the NW or W in winter, and from the NW, SW, and SE in summer.

Fig. 2a shows space between buildings, an adequate court, and a good windbreak for windy

climates. But, the house is SE of the livestock, so some winter winds will carry odors to the living area. If possible, plan the house further west or southwest and the livestock center further north-east.

In Fig. 2b a straight drive would permit north and northwest winds to blow directly toward the court. The layout can be improved by exchanging the house and machinery centers and using the alternate drive location shown.

In general, study prevailing wind directions. Position the house so that fewest winds blow toward it from the rest of the farmstead during the times of the year when dust, noise, odors, and insects are problems. Using the zones as described, locate the other activity areas.

FARMS AND FARM BUILDINGS

All buildings should be arranged so that they can be reached by truck. The service yard and drives should allow plenty of room for traffic. Buildings can be planned so that there are large doors with plenty of head room and no interior posts. If buildings are planned this way then a tractor with a blade can clean livestock buildings and loading and unloading can be a mechanical operation instead of back-breaking labor. Figure 1 shows traffic flow.

A good farmstead plan takes advantage of natural influences. The sun's movement from east to west warms three sides of buildings if they are laid out square with the compass. Some buildings—such as corncribs, two-row central farrowing, and stanchion barns need the warmth or light of the sun on both the east and west. For that reason they should be built with the long axis north and south. Poultry laying houses and one-row farrowing houses usually face south and have most of the windows on the south side (Fig. 2).

Buildings can usually be placed so that they will shield workers and animals from winter wind without making it any harder to do the chores. Putting major openings and windows on the south and east will trap the sun's heat and, thus, give additional protection from the cold. The sun will also help to dry out livestock buildings where too much moisture is often a problem.

Service yards, barn lots, and farm structures require well-drained locations. The service area should, of course, drain away from the farmhouse. Raised ground is ideal for a farmstead setting—giving scenic advantages as well as good drainage—but a gentle slope in one direction can often be developed effectively.

Rolling land can add interest to a farmstead setting. And, if it is properly handled, it need not interfere with the efficiency of operations. An arrangement that follows the contour of the land will make maintenance easier and will improve appearance. Sometimes it may be necessary to reduce the slope or improve drainage by grading.

Living Center

The farmhouse should be fitted into its surroundings. Sunlight, direction of prevailing summer and winter winds, views (both those that already exist and those that can be developed), and location of the public road and driveway should all be considered (Fig. 3).

If the doors are on the east or the south side of the garage, you will have less trouble with snow than if they are on the north or west.

Farm Service Yard

A farm service yard makes it easy to get from one activity center of the farmstead to another. It reduces the number of gates necessary—or does away with them entirely. It provides room to maneuver farm machinery and helps make the whole farmstead look more unified. The space in the yard gives some fire protection

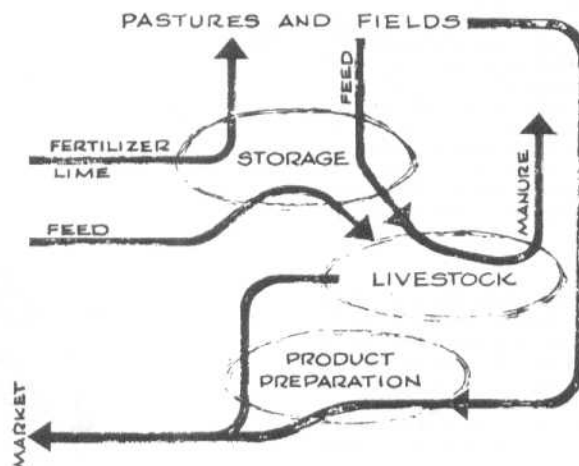

Fig. 1

Fig. 2

Fig. 3

From *Farm Arrangements*, published by the Boy Scouts of America.

FARMS AND FARM BUILDINGS

without increasing the distance that has to be traveled from one building to another. Lights near the center of the yard will illuminate the approach to all buildings and lots (Fig. 4).

The service yard should have direct access to fields and to the road. Where the service yard or lanes enter fields, cattle guards can often be used to advantage instead of gates. Notice the grate in the lane that discourages cattle from crossing, but does not prevent walking or driving a vehicle over it.

The service yard's dimensions, of course, depend on the size of the farm and the number of enterprises. Eighty feet or eight poles is the minimum width needed where vehicles are to be turned around, and a greater width is better.

The yard may be square, rectangular, L-shaped, or of any other shape—just so it remains uncluttered. Gravel or crushed rock is desirable where traffic is heaviest. Other areas should be sodded to improve the appearance.

Machinery Center

Keep farm machinery in a central storage building rather than distributed around the farmstead in driveways, small sheds, or lean-tos of livestock buildings. An advantage of the machinery center is that it is more convenient for making repairs and servicing equipment. If the automobile is kept there, the building should be closer to the house than would otherwise be desirable.

Sometimes the machinery center may be located along the lane to the fields. This is desirable if space in the farmstead area is limited or if all machinery traffic is confined to lanes within the farm. The warehouse type of building (with end doors) can be set just to one side of the lane. The side-opening type of structure needs to be at least 30 ft or 3 poles from the lane for convenience in getting in and out (Fig. 5).

Unless room is allowed for expansion, future shelter space may have to be separate. A location that will allow an extension on one end is desirable.

Grain Center

Usually grain is stored at the farmstead, although some grain farms have cribs in a field near a good market road. Storage at the farmstead reduces the chance of loss by theft and is also more convenient if a substantial amount of grain is fed on the farm (Fig. 6).

A spot within the service yard is best—preferably near one side where there is ample room for the use of elevators, trucks and wagons. The grain center should be accessible without opening gates. If natural drying is depended upon, a location where sunlight and air can reach the walls of cribs is important.

The grain center itself may be a crib, a combined crib and granary, or one or more grain bins. Elevating, filling, and emptying equipment can be arranged so that all grain is stored at ground level. Bins may be placed either in a circle around an elevator or in a straight line along the service yard border (on livestock farm, they may be next to the feeding area).

When the grain center is combined with a feeding center, space should be allowed for a structure to house feed-processing equipment. If the grain center has been properly related to the feeding center, the feed can be easily fed to the livestock.

Feeding Center

On livestock farms the grain storage and processing center that has been described should

Fig. 4

Fig. 5

Fig. 6

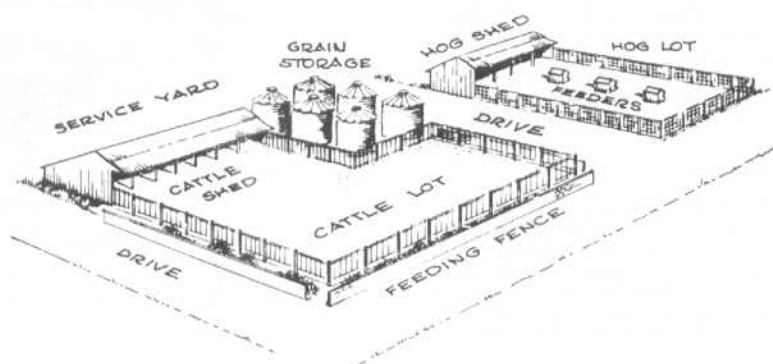

Fig. 7

FARMS AND FARM BUILDINGS

be one of the units making up the feeding center. Shelters for one or more classes of livestock, storage units for feed and bedding, lots, and feeding floors would also be included. Putting grain storage close to these other structures will, of course, save labor. Precautions against lightning and spontaneous combustion will help to take care of any increased fire hazard (Fig. 7).

In arranging the feeding center, take into account both sunlight direction and the direction of prevailing winds. Protection from winter wind is, of course, important—at the same time sheltered areas should get as much sunlight as possible. The center should be located so that the prevailing summer wind carries livestock odors away from the living area.

Structures for storing hay, silage, and bedding should be easy to get to from the service yard. Filling them will then be more convenient. For greater convenience, arrange the feeding area so that it does not have to be entered when grain is being unloaded for storage.

Paved feed lots are highly recommended. Feed lots for both cattle and hogs are best located near the feed storage and processing center. This is not always possible, however, when existing arrangements are being adapted for modern feeding equipment. In such a situation a mechanical conveyor or a blower-pipe arrangement might be used to move feed to bunks some distance away from the immediate feed center.

Dairy Center

Dairy structures (loose-housing or stanchion barn systems) should be on the side of the service yard closest to lanes and pastures.

The most compact system uses the stanchion barn. Usually, the long axis of the barn is north and south so that sunlight will strike both sides of the building. Exceptions, however, present no serious difficulties. The milk house or milk room is preferably located near the middle of the stanchion area and on the service yard side. Sometimes a short driveway from the service yard to the milk room may be necessary. For efficiency in feeding, the silo and feed room should also be about halfway from each end of the stanchion lines—usually on the side opposite the milk room. Where possible, the silo and feed storage should be accessible from the service yard, but this is less important than access to the milk room if a choice must be made (Figs. 8 and 9).

The loose-housing system consists of several units: a feeding area and hay storage, a bedded area and bedding storage, a milking unit with feed bin, and a milkhouse. It is less expensive to build but takes more space. These units should be arranged to allow sunlight in the bedded area while shielding the space from winter wind. An L-shape arrangement can often be formed with one side of the L made up of the bedded area and bedding storage. The other side would consist of the feeding area and hay storage. Sometimes the location of the service yard may make a straight-line arrangement desirable, although such an arrangement gives less wind protection than the L-shape. Doors to hay and bedding storage should be accessible from the service yard or from a lane leading to the yard.

The bunker silo is supplied and packed by tractor. Silage is protected by a waterproof covering that is rolled back gradually to permit feeding all across one end.

The milking unit should be located between the bedding and feeding areas. To reduce steps, the milk house should be near the milking unit. With pipeline equipment, it is important

Fig. 8

Fig. 9

Fig. 10

FARMS AND FARM BUILDINGS

Fig. 11

Fig. 12

to locate the milk house so that a minimum of piping is required.

Poultry Center

The following suggestions are made for typical farm poultry enterprises—not commercial poultry establishments (Fig. 10).

Provide a definite poultry center rather than allow a run-of-the-farmstead arrangement. As a general rule, it should be where the prevailing summer wind will carry odors and feathers away from the living area rather than toward it. Other than that, the location will depend on the system of handling the flock.

Adult stock should be confined to the house or at least kept in a fenced yard. If you use a poultry yard, you may wish to rotate it with the garden. This system has advantages for sanitation as well as for productive gardening. But never apply poultry manure during the gardening year.

When poultry is confined, the house should be readily accessible from the service yard. Often a good location is next to the border of the service yard, provided there is enough space to allow for future expansion of the poultry house.

Unless the operation is large enough to justify storing feed within the poultry house, the house should be fairly close to the feed center. A southern exposure that will admit the maximum amount of sunlight is also important. Water should be piped into the house.

Power, Water, and Sanitation Facilities

A well located in the living area of the farm is desirable from a sanitary standpoint, since the house should be on the best-drained area of the farmstead. You may, however, prefer a location closer to the center of water consumption or between the house and the livestock

feeding area. Direct access to the well from the service yard is desirable but not necessary.

The leader supplying electricity to the pump should come directly from the meter. In laying out the water system, it is important to keep lines as short and straight as possible. A pipeline run straight to the barn from the storage tank, with side branches to the poultry house, hog house, pastures, shop, and garden is practical in most situations (Fig. 11).

A modern sewage disposal system consists of the house sewer, septic tank, and a disposal field. The sewer line from the house to the septic tank, as well as the line to the distribution box, must be watertight and rootproof. The disposal area should be on open ground, generally out of range of tree roots.

Windbreak

Good planning guards against winter winds. Because the winter wind is normally from the northwest, the windbreak of trees should be planted on the north and west sides of the farmstead (Fig. 12).

On level or nearly level land, the ideal distance between windbreak and areas requiring the most protection such as house, livestock shelter, and feeding areas—is about 150 ft or 15 poles. The maximum distance is 300 ft or 30 poles. Since the zone of noticeable protection is equal to about ten times the height of the trees, they would have to be 30 ft high before giving protection to areas 300 ft away.

At the same time the windbreak should not be closer than 5 poles to commonly used areas, and 8 or 10 poles would be better. Snow may accumulate in the immediate lee of the windbreak, particularly during the early years of planting. Also, air movement in summer is poor as soon as the trees grow tall enough to give protection. Buildings infrequently used in winter may stand near the windbreak, provided

roofs are steep enough to keep snow from accumulating. Poultry and livestock sensitive to heat should not be kept in these buildings during the summer.

For satisfactory protection, trees should be in three rows 14 ft apart. A permanent fence around the windbreak is essential to keep out livestock and poultry. It should be at least 6 ft from the rows of trees, making the total minimum width 40 ft or 4 poles. Length of the windbreak depends largely upon the size and shape of the farmstead. It is often desirable to extend the windbreak 5 to 10 poles past the area needing protection.

While the windbreak will ordinarily follow the straight lines of field and lot boundaries, a diagonal or curved line may sometimes be desirable. For example, where the land surface slopes sharply to the northwest away from the farmstead area, planting the trees on the contour will place them higher on the slope, giving earlier protection. Or it may be possible to avoid a poorly drained area with a curve or diagonal arrangement.

For the best protection, the windbreak should be continuous and uninterrupted. So if possible, access to fields on the north and west should be at either end of the windbreak. If a lane through the windbreak is necessary, open gaps should be avoided, especially at the critical northwest corner. If the lane logically fits here, and principal traffic is to the north, the north-south strip should extend about 5 poles beyond the east-west strip. This arrangement will protect the opening from all winds of the northwest quarter except those in the north.

If it is necessary to have a gap at some point along the strip, the corner section should be farther from the farmstead than the end section. This arrangement is advantageous for a farmstead that narrows toward the east or south.

ANIMAL FACILITY, LABORATORY

The physical condition and design of animal facilities to a great extent determine the efficiency and economy of their operation and greatly influence standards for animal care. A well-designed, properly maintained facility is an essential element in good animal care.

Functional Areas

The design, scope, and size of an animal facility depend on the nature of the research activities to be conducted therein, the number of animals to be housed, the requirements for flexibility in the housing of different species, its physical relationship to the rest of the institution, and its geographical location. The following functional areas are considered essential in a modern animal facility:

1. A separate building, a separate wing, one or more floors, or separate rooms where animals can be housed apart from areas of human occupancy. A sufficient number of animal rooms or areas are required to assure separation of species when necessary, or isolation of individual projects; to provide for the receipt, quarantine, and isolation of animals; and to provide for their routine and specialized housing.

2. Specialized laboratories or areas contiguous with or near the animal housing areas for activities such as surgery; necropsy; intensive postsurgical care; radiography; preparation of special diets; and the diagnosis, treatment, and control of laboratory animal diseases. If radioisotopes, toxic substances, or pathogens are to be used, special facilities or areas must be provided.

3. Receiving and storage areas for food, bedding, supplies, and equipment.

4. An office for the administration, supervision and direction of the facility.

5. Showers, sinks, lockers, and toilets for personnel.

6. An area for washing and sterilizing equipment and supplies.

Depending upon the volume of work, a well-equipped cleaning area includes facilities such as a cage-washing machine; a bottle- or glassware-washing machine; a rack-washing machine or area; a waste can-washing machine or area; a utility sink; an autoclave for equipment, food, and bedding; and separate areas for holding soiled and clean equipment.

7. An incinerator capable of burning all animal waste and refuse, or facilities for safe and sanitary storage of such waste prior to removal.

8. An area suitable for food consumption should be provided if personnel regularly eat in the facilities that house animals.

Service Areas in Relation to the Total Size of the Animal Facilities

1. An area or areas equal in square feet to at least 25 percent of the animal housing space should be set aside for the service functions of the animal facility. The service functions in-

clude such activities as cage washing and sterilization, storage, diagnostic laboratory and office activities, receiving and quarantining of animals, and refuse disposal.

2. Where an animal facility is 1,000 sq ft or less in size, it may be possible to carry out the service functions in an area that serves other activities as well. However, a separate facility should be available for washing and sanitizing animal cages.

3. In a facility up to 10,000 sq ft in size, separate rooms or areas should be provided for the following service activities:

- a. Receipt and quarantine of newly received animals

- b. Receipt and storage of animal food and supplies, including refrigeration

- c. Cleaning, sanitizing, and storage of cages and equipment

- d. Incinerator or protected area for refuse

- e. Lavatory facilities for personnel

- f. Office for supervisory and administrative personnel

- g. Laboratory facilities

4. In institutions having several separate animal housing facilities, or one large area, which total more than 10,000 sq ft, rooms or areas should be provided for all of the service functions listed in item 3 above. In addition, clinical laboratory facilities should be provided for the diagnosing of animal diseases.

Some duplication of service areas may be required if the animal facilities are widely dispersed.

Physical Relationship of Animal Facilities to Research or Teaching Laboratories

Animal housing areas support research and teaching laboratories. Good animal husbandry and human comfort require physical separation of animal facilities and human occupancy areas such as offices and laboratories. This can be accomplished by locating the animal quarters in a separate wing or on a separate floor in a multistory building, or by providing a separate building for animal housing. A one-story building for animal housing permits the most efficient and economical animal care operation, since vertical transport is avoided; however, this may be the least desirable choice for the research workers because of inaccessibility to their laboratories. Efficiency and economy in utilization of the research workers' time must be considered in planning animal facilities. Careful planning should make it possible to locate the animal areas adjacent to or near the laboratory areas; but they should be physically separated from the laboratories by barriers such as entry locks, separate corridors, or separate floors.

Many institutions have recently acquired and developed farm type facilities. These are useful for conditioning, isolation, quarantine, and long-term housing and maintenance of large domestic animals.

Construction Guidelines

Maintenance costs as well as initial construction costs should be considered when selecting building materials, and these materials should facilitate efficient and hygienic operation of the

animal quarters. Durable, waterproof, fire-resistant seamless materials are most desirable for interior surfaces. Paints and glazes, in addition to being highly resistant to chemical solvents, cleaning agents, and scrubbing, should be highly resistant to high-pressure sprays and impact.

1. **Corridors** Corridors should be at least 7 ft wide to permit easy flow of personnel and equipment. The floor-wall junction should be coved to facilitate cleaning. Provisions should be made for curbs or guardrails or for bumpers on equipment to protect the walls from damage. Exposed corners should be protected by reinforcing them with steel, or another durable material up to a height of 6 ft. Corridors leading to dog kennels should be provided with a noise trap such as a double-door entry lock. Wherever possible, access to utilities such as waterlines, drainpipes, and electrical connections should be through service panels or shafts located in the corridors outside the animal rooms.

2. **Animal Room Doors** Animal room doors should swing toward the corridor only if there is a recessed vestibule. They should be at least 42 in. wide and no less than 84 in. high to permit easy passage of racks and equipment. The doors should fit tightly within the frames and sills, and the frames should be completely sealed to provide a barrier against the entrance or harboring of vermin. Metal or metal-covered doors are preferable. They should be equipped with kickplates and be self-closing. Recessed handles are recommended. Viewing windows are desirable.

3. **Exterior Windows** Exterior windows and skylights are not needed in the animal rooms if adequate ventilation and lights are provided. If windows are provided, it is preferable that they be nonopening, without sills or horizontal surfaces where dust can collect, of an insulating construction (in areas of temperature extremes), and sealed with a material that will withstand repeated washing and disinfecting. If windows are opened for ventilation purposes, effective screening is essential.

4. **Floors** Floors should be smooth, waterproof, nonabsorbent, nonslip, wear resistant, acid and solvent resistant, capable of being scrubbed with detergents and disinfectants, and capable of supporting racks, equipment, and storage areas without gouging, cracking, or pitting. Depending upon the functions carried on in specific areas, the materials specified should be of a monolithic nature or should have a minimum of joints. Some materials that have proven satisfactory are terrazzo, cupric oxychloride cement, smooth hard-surfaced concrete, neoprene terrazzo, and special hardened rubber-base aggregates. A continuous waterproof membrane should be provided. Where sills are installed at the entrance to the room, they should be designed so as to allow for the passage of equipment.

5. **Walls** Walls should be monolithic, waterproof, painted, glazed or smooth, free of cracks or imperfect junctures at the door, ceiling,

ANIMAL FACILITY, LABORATORY

corners, or utility penetrations. Materials should be acid or solvent resistant, capable of withstanding scrubbing with detergents and disinfectants. The walls must be capable of withstanding water under high pressure. Provision should be made to protect walls from damage by movable equipment.

8. Ceilings Ceilings formed by the concrete floor above are satisfactory if properly smoothed, sealed, and painted. Furred ceilings of plaster or fire code plasterboard should be sealed and painted with a washable finish. Exposed pipes and fixtures at ceiling level are undesirable, especially in nonhuman primate rooms, because of the problems created by escaped animals.

7. Ventilation, Temperature, and Humidity Control

a. Effective ventilation is necessary to maintain a low concentration of atmospheric contaminants, such as odors or microorganisms, to regulate room temperature and to promote comfort. Important factors for proper ventilation are temperature, humidity, and air movement. The ability to maintain odorless facilities depends upon the number and species of animals housed, and the sanitation practices, as well as upon a properly designed ventilation system.

b. Ideally, a system should permit individual adjustments within $\pm 2^\circ\text{F}$ for any temperature within a range of 65° to 85°F . The relative humidity should be maintained year round within a range of 30 to 70 percent, according to the needs of the species being maintained. A mechanical ventilation system is necessary in most indoor facilities to meet these requirements. Air conditioning is highly recommended since it promotes environmental stability. Temperature and humidity should be controlled individually in each animal room or groups of rooms serving a common purpose. The animal facility and human occupancy areas should be ventilated separately. The system should provide frequent changes of room air without drafts. Ten to fifteen changes per hour are recommended. There should be no recirculation of room air unless it has been filtered to remove contaminants. An acceptable alternative is to provide zone control with limited recirculation of room air. Operation of the system at $74^\circ \pm 4^\circ\text{F}$ and 50 ± 20 percent relative humidity, using 100 percent fresh air during temperate weather and 50 percent fresh air during periods of temperature extremes is acceptable for situations where routine housing of animals is the primary requirement.

c. Maintenance of a given room temperature within even closer tolerances, such as $\pm 1^\circ\text{F}$,

and of relative humidity within 5 percent, using 100 percent fresh air at all times, may be required for certain experiments. Such controls may be essential, for example, where precise environmental studies are in progress. Recording devices for temperature and humidity should be installed in such rooms, together with a failure alarm system that may control utilities and air supply. The sensing elements should be placed at approximately the average level of the animal cage floors.

d. If small animals (for example, dogs and rabbits) are housed outdoors with no access to indoor facilities, provisions to aid their natural temperature regulation are essential. When the ambient temperature falls below 50°F , some form of shelter and clean nesting materials should be provided. Materials such as shavings, straw, or paper can be used. When the ambient temperature exceeds 85°F , shade must be available and animals should be able to burrow or lie on materials several degrees cooler than the surrounding air.

8. Power and Lighting The electrical system should provide ample lighting, sufficient power outlets, safety provisions (such as explosion-proof outlets in rooms where volatile, explosive anesthetics may be used), and water-proof outlets where water is used in cleaning.

Suggested Space for the Routine Housing of Laboratory Animals

Species	Weight or age	Type of housing	Overall size (inches)			Number of animals	Housing area/animal	
			Width	Depth	Height		Sq ft	Sq in.
Dogs*	Up to 15 kg	Pen or run	48	72	...	3	8	
	15 to 30 kg	Pen or run	48	72	...	2	12	
	Over 30 kg	Pen or run	48	72	...	1	24	
	Up to 15 kg	Cage	36	32	32	1	8

ANIMAL FACILITY, LABORATORY

9. Drainage All waste fixtures and equipment should be connected to soil and waste pipes through traps. If floor drains are used, the drainpipes should not be less than 4 in. in diameter. In heavy-use areas such as dog kennels, drains at least 6 in. in diameter are recommended. A flushing drain, much like an ordinary toilet bowl, set in the floor, is an effective aid in the disposal of solid waste. A porous trap bucket to screen out solid waste provides an effective alternative to removal of solid materials through the drain. All drainpipes should have short runs to the main, or they should be steeply pitched from the opening. When drains are not in use they should be capped and sealed to prevent any backflow of sewer gases. Lockable drain covers are useful in preventing use of the drains for disposal of materials which should be swept up and removed by other means.

Floor drains are not essential in animal rooms for species such as rats, mice, or hamsters. Floors in such rooms can be maintained satisfactorily by wet vacuuming, or by sweeping and mopping with appropriate disinfectants or cleaning compounds. The recommended minimum pitch of floors, where floor drains are used, is $\frac{1}{4}$ in. per foot. Proper pitching of the floor is an essential element in establishing good drainage in animal rooms;

particular attention should be paid to this detail in planning animal facilities.

10. Storage Areas: Food and Bedding, Refuse, Equipment In areas where delivery schedules are reliable, the amount of space required for food and bedding storage can be held to a minimum. The best utilization is achieved by maintaining constant turnover.

Bulk supplies of food and bedding should not be stored in animal rooms. A separate area or room should be available in which food and bedding can be stored off the floor on pallets, racks, or carts. A continuing pest control program is essential. It is most desirable for the storage areas to be verminproof.

Food storage areas should be physically separated from refuse areas. Temperatures in the storage rooms may be the ambient temperature. However, it is good practice to hold packaged animal feeds (pellet rations) at 50° F or less. Refrigerated storage should be available for meats, fruits, vegetables, and other perishable items.

Separate storage for animal waste and dead animals is essential. Refuse storage areas should preferably be kept below 45° F to reduce putrefaction of waste or animal carcasses. Obnoxious materials should be covered or packaged. The area should be constructed so

that it can be kept clean and free of vermin.

Adequate space for storing equipment is essential. This is an effective way to prevent clutter in animal rooms. All storage areas should be kept clean.

11. Noise Control Noise, both from the animals and animal-care routines, is inherent in the operation of animal facilities. Noise may be undesirable because of its effect on personnel and on the animals themselves. Inasmuch as background and "operational" noise are an environmental factor in the control of animal experiments, they should be considered in the design of animal facilities.

Ordinarily, species such as rats, mice, guinea pigs, cats, and hamsters do not create a disturbing amount of noise in animal facilities. Noise from a monkey colony can be troublesome, and, invariably, dogs are the cause of unwelcome noise. Barking is disturbing to personnel working inside and outside of the animal facilities. It may also pose important public relations problems if there are residences near the laboratory.

The physical separation of human and animal occupancy areas is the best way to minimize all disturbances to laboratory personnel from the sounds of animals and animal-care routines.

Suggested Space for the Routine Housing of Laboratory Animals (Continued)

Species	Weight or age	Type of housing	Overall size (inches)			Number of animals	Housing Area/animal	
			Width	Depth	Height		Sq ft	Sq in.
Pigeons	0.5-0.8 kg	Cage	30	30	15	5-7	130-180
Small birds	100-130 g	Cage	8	10	8	1-2	30-80
	100-130 g	Group cage	24	30	8	24	30
Cattle (adult)	350 kg	Stanchion	42	58	1		
	450 kg	Stanchion	45	60	1		
	550 kg	Stanchion	48	64	1		
	650 kg	Stanchion	51	68	1		
	750 kg	Stanchion	54	72	1		
	550 kg	Pen	120	144	1	120	
	650 kg	Pen	120	168	1	140

Female with young	Pen	20-30	
Adult male	Pen	1	20-30	
Hogs
Adult sow	Pen	1	25-40	
Sow with pigs	Pen	1	48-88	
Adult boars	Pen	1	30-80	
	18-45 kg	Pen	6-12	
	45-100 kg	Pen	12-16	

* These recommendations may require modifications according to the body conformations of particular breeds. As a further general guide, the cage dimensions should be: (a) the height of the dog at the withers, plus at least 6 in. (height); (b) the length of the dog from the tip of the nose to the base of the tail, plus at least 6 in. (width and depth).

† These recommendations may require modifications according to the body conformations of particular species.

‡ Provide ample head room to stand erect without crouching.

¶ Loose housing is outdoor housing that includes an open shed for shelter.

ANIMAL FACILITY, LABORATORY

12. Facilities for Washing and Sterilizing Equipment and Supplies An area for washing and sterilization is essential to keep equipment physically clean, reduce obnoxious odors, minimize the spread of infectious diseases, and provide for the comfort of experimental animals. Washing and sterilizing are best done outside of the animal rooms in an area specifically designed for the purpose and centrally located, if possible. Consideration should be given to such factors as:

- a. Location with respect to animal rooms, traffic flow that separates "clean" and "dirty" areas, elevators, ease of access, and disposal of waste.
- b. Soundproofing.
- c. Utilities such as hot and cold water, steam, floor drains, and electric power.
- d. Proximity to cage and equipment storage areas. It is essential to provide separate holding areas for soiled and clean equipment.

e. Insulation of walls and ceilings where necessary.

f. Ventilation with installation of proper vents and provisions for dissipation of steam.

g. Access doors of sufficient width to assure free movement of equipment.

Large Animals

For general purposes, large animals are defined as domestic animals, such as horses, sheep, cows, goats, and pigs.

Conventionally, these animals are housed in pens and barns. Even when ambient temperatures fall below freezing, most large animals prefer to remain outdoors if adequate feed, water, bedding, and shelter are available.

The housing of large, domestic animals in an urban research facility will parallel in many respects the housing of other laboratory animals. Because of their size, however, special

consideration must be made for their restraint and confinement.

Space Recommendations for Laboratory Animals

The size of a cage, pen, or run, and the number of animals to be housed in each, are matters of professional judgment. The recommendations in the preceding table are based on the best available information concerning reasonable space allocations for the routine housing of animals in experiments. They are included here as a guide, recognizing that it is impossible to delineate cage sizes with greater precision due to varied research requirements. As has been implied the adequacy of the housing system must be under continuous review. More detailed housing standards for laboratory animals are available from the Institute of Laboratory Animal Resources, National Academy of Sciences-National Research Council.

A greenhouse must be so designed that it admits the greatest possible amount of available light.

The structural system, therefore, must be minimal in bulk, yet strong enough to support the weight of the glazing system. Site selection, building orientation, and roof pitch must all be considered with this in mind. While the glazing medium selected must be capable of high light transmission, it must also be of a weight and kind and be framed so that breakage is a minimal hazard.

A greenhouse is a transparent structure and cannot be insulated, so solar heat gain and heat loss are factors that must be considered. In spite of the difficulties inherent in the type of structure, temperature and humidity must be controlled to within a degree and a half in some cases. Then, too, plant requirements vary from dawn to dusk to dawn, and from one stage of plant growth to another.

A temperature control system specifically designed for horticultural applications (rather than conventional heating and cooling systems) must be installed in the greenhouse to create and maintain correct environmental conditions in a consistent manner.

There must be a means of introducing fresh air into the greenhouse on demand, and circulating it in an even pattern so that temperature and humidity levels are uniform throughout the house.

Instead of simple fenestration the greenhouse must be supplied with some type of ventilating sash and/or a system by which air is introduced by negative pressure and distributed through transparent ductwork, such ventilating systems being thermostatically controlled.

Greenhouses are sometimes used for other purposes than plant production alone. Some are also teaching labs, research stations, or display houses. Some must have greater degree of aesthetic appeal than others, or conform to existing architecture.

While good light exposure, unpolluted air, and free-draining soil are all basic requirements of a plant-growing environment, greenhouses often have to be sited on crowded campuses and in industrial areas.

While the greenhouse designer does not always have a free choice when it comes to site selection, some requirements are indispensable.

For instance, the greenhouse site should not be shaded by buildings or trees. Good natural exposure is preferable to a site where hills cut off late afternoon sun. A windbreak 100 or more feet away in the direction of the prevailing wind can help reduce heating costs.

Avoid sites downwind of a heating plant or incinerator stack, or where toxic fumes from chemical laboratories can be drawn into the greenhouses. Proximity to fruit or vegetable

storage areas should be avoided because plants are sensitive to ethylene. If greenhouses are to be near other buildings, avoid if possible dark paved surfaces and heat-absorbing walls, which contribute to summer heat buildup. Low-

lying ground has a tendency to flood during thawing out periods.

And for obvious reasons greenhouses should not be located adjacent to playgrounds or playing fields.

Greenhouse Guidelines

Greenhouse for use by	Function of greenhouse operation	Greenhouse design considerations
High school	Growing and/or maintaining small number of plant specimens for observation.	Space-10 sq ft per student enrolled in course. Requires consistent, day-to-day control of environment.
Vocational school	Providing basic experience in commercial crop production.	Space-20 sq ft per student enrolled in course. Greenhouse should be small-scale edition of commercial operation with three separate temperature zones: 50-55° min., 60° min., & 65+° min.
Liberal arts college, university	Growing and/or maintaining plant specimens. Simple research projects involving small number of plants.	Space-10 sq ft per student using dept. Often greenhouse is part of Science Building complex and must conform to other architecture or site. Many configurations possible.
Agricultural colleges	Simulating commercial production of plant materials. Propagating and finishing zones. One or more crops, such as cut flowers, pot plants, vegetables, ornamentals, etc.	Space-100+ sq ft per student in dept. Layout, facilities, equipment, controls should be designed for horticultural applications and equal to those used by commercial growers.
Scientific research	Complex research projects involving numerous plants, multiple compartments for separate climates, precise data recording. May require separate cluster of working greenhouses for major research projects.	Space-Varies from 250 sq ft up per growth chamber or compartment, depending on type of research.
Public conservatory	Display of plant collections. Usually provides three climates-tropic, temperate, arid. May require separate cluster of working greenhouses for plant production. Municipal conservatories often grow plant materials for all civic planted areas.	Space-1 1/2 acres per million population. Provide 40,000 sq ft working greenhouses to 20,000 sq ft display area. Display buildings are enhanced by acrylic glazing, design-oriented structural systems. Criteria for working greenhouses same as for commercial.
Commercial growing operation	Actual production of plant materials. May include all stages from propagating to finishing of single or multiple crops.	Space-40,000 sq ft min for profit. Glaze with glass, fiber glass, combination, use sloping or curved roof profile. Provide 1,000 sq ft service area for 6,000 sq ft growing area. Maximum environmental control justified on basis of increased profitability. Single or multiple units, compartmentalized or open ridge and furrow.
Hobby gardening	Growing and/or maintaining small plant collections, forcing bulbs, rooting seedlings, etc.	Space-100 sq ft min. Small prefabricated bldg. with environment package provides neat-appearing, horticulturally adequate unit.

HORSE BARN

Properly designed, constructed, and arranged horse buildings and equipment give increased animal comfort and performance, greater efficiency in the use of feed, and less expenditure of labor in the care of horses. Also, attractive barns add to the beauty of the landscape. In serving these purposes, barns need not be elaborate or expensive.

BUILDINGS

The primary reasons for having horse buildings are (1) to provide a place in which to confine horses and store feed and tack and (2) to modify the environment by controlling temperature, humidity, and other factors.

Types and Sizes of Horse Barns

Needs for housing horses and storage of materials vary according to the intended use of the build-

ings. Broadly speaking, horse barns are designed to serve (1) small horse establishments that have one to a few animals, (2) large horse-breeding establishments, or (3) riding, training, and boarding stables.

Various types and sizes of stalls and sheds are used in horse barns. However, in all types except the breeding shed, ceilings should be 9 ft high and doors should be 8 ft high and 4 ft wide. The breeding shed should have a ceiling 15 to 20 ft high and a door wide enough to permit entrance of vehicles.

The recommended plans for different kinds of horse barns are as follows.

Small Horse Establishments These horse barns are for housing pleasure horses or ponies or raising a few foals (Fig. 1). Box stalls should be 12 ft square and tie stalls should be 5 ft wide and 10 or 12 ft long.

Build the stalls in a row and provide a combination tack and feed room for units with one or two stalls. Use separate tack and feed rooms for units with three or more stalls. Generally, not more than a 1-month supply of feed is stored

at a time. The use of all-pelleted feed lessens storage-space requirements.

Large Horse-Breeding Establishments Large establishments need specially designed buildings for different purposes. They are as follows:

1. *Broodmare and foaling barn.* This can be a rectangular building either with a central aisle and a row of stalls along each side or with two rows of stalls back to back surrounded by an alley or runway, i.e., of the "island" type. Most broodmare stalls are 12 ft square, although they may be up to 16 ft square. A stall 16 ft square is desirable for foaling. A broodmare barn needs an office for records; toilet facilities; hot water supply; veterinary supply room; tack room; and storage space for hay, bedding, and grain.

2. *Stallion barn.* This barn provides quarters for one or more stallions. It should have a small tack and equipment room, and it may or may not have feed storage. The stalls should be 14 ft square.

Provide a paddock near the barn or, if possible, adjacent to it. The paddock can be any shape, but each side should be at least 300 ft long.

Breeding and Raising Horses, Agriculture Handbook #394, U.S. Dept. of Agriculture, Washington, D.C., 1972.

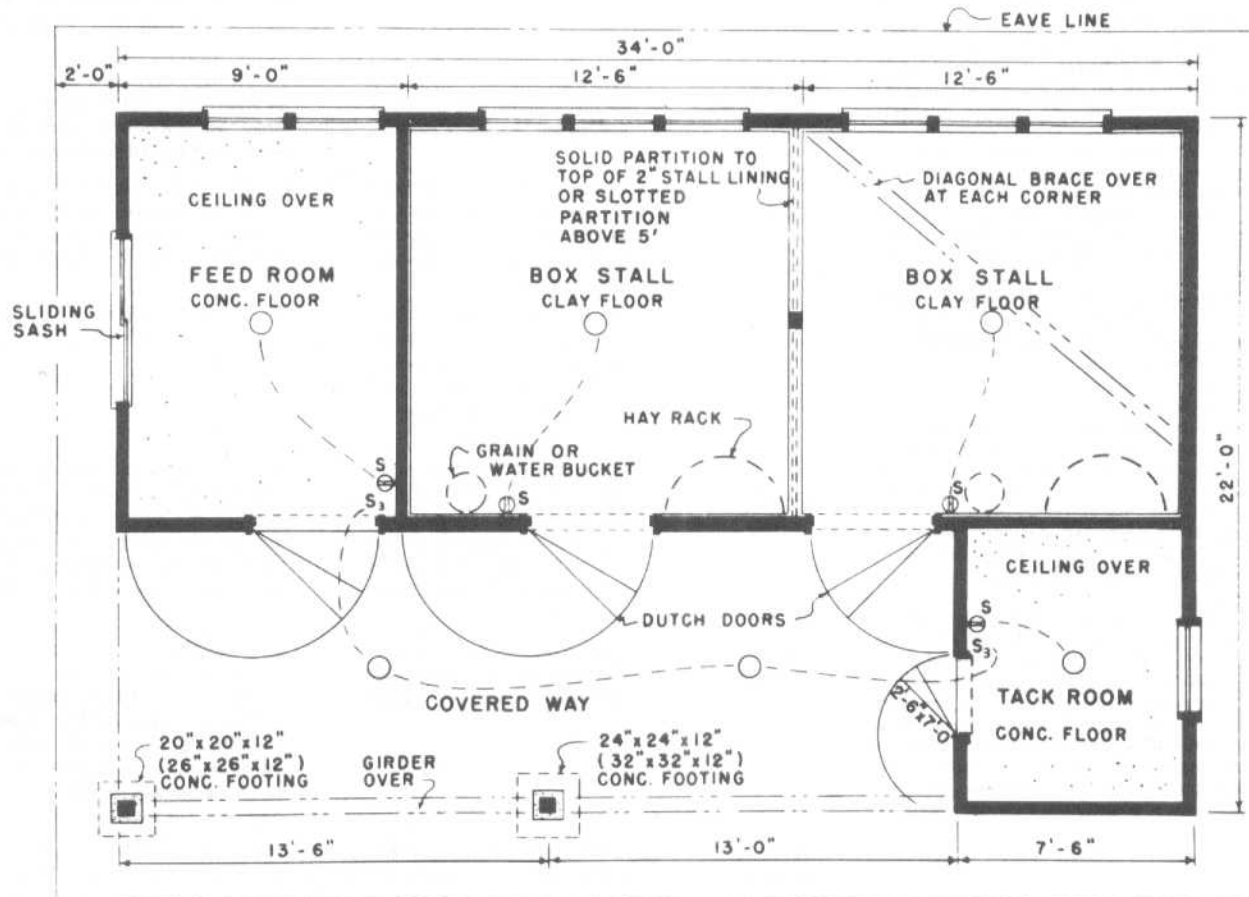

Fig. 1 Horse barn floor plan. Barn has two box stalls, a feed room, and tack room.

3. *Barren mare barn.* Use an open shed or rectangular building that has a combination rack and trough down the center or along the wall. Provide storage space for hay, grain, and bedding. Allow each animal 150 sq ft of space.

4. *Weanling and yearling quarters.* Either an open shed or a barn with stalls may be used. Both weanlings and yearlings may be kept in the same building, but different age and sex groups should be kept apart. When stalls are used, two weanlings or two yearlings may be kept together. Stalls should be 10 ft square.

5. *Breeding shed.* This should be a large, roofed enclosure that has a laboratory for the veterinarian, hot water facilities, and stalls for preparing mares for breeding and for holding foals. The shed should be 24 ft square.

6. *Isolation quarters.* These quarters are for sick animals and animals new to the farm. Use a small barn that has feed and water facilities and an adjacent paddock. Stalls should be 12 ft square.

Riding, Training, and Boarding Stables For this purpose, the quarters may consist of (1) stalls constructed back to back in the center of the barn with an indoor ring around the stalls, (2) stalls built around the sides of the barn with the ring in the center, or (3) stalls on either side of a hallway or alleyway and the ring outdoors. Box stalls should be 10 to 12 ft square and tie stalls should be 5 ft wide and 10–12 ft long.

Environmental Control

Animals perform better and require less feed if they are raised under ideal conditions of temperature, humidity, and ventilation. Environmental control is of particular importance in horse barn construction because many horses spend most of the time in a stall. The investment in environmental control facilities must be balanced against the expected increased returns because there is a point where further expenditures for environmental control will not increase returns sufficiently to justify added cost.

Before the building is designed, it is necessary to know how much heat and moisture a horse

produces. Body heat production varies according to body weight, rate of feeding, environmental conditions, and degree of activity. Under average conditions, a 1,000-lb horse produces about 1,790 British thermal units (Btu) per hour, and a 1,500-lb horse about 2,450 Btu per hour. A horse breathes into the air approximately 17.5 lb, or 2.1 gal, of moisture per day.

Until more experimental information is available, the following environmental control recommendations, based on confinement systems used for other classes of animals, may be followed.

Temperature A range of 45 to 75° F is satisfactory, with 55° considered best. Until a newborn foal is dry, it should be warmed to 75 to 80°. This can be done with a heat lamp.

Humidity A range of 50 to 75 percent relative humidity is acceptable with 60 percent preferred.

Ventilation The barn should have as little moisture and odor as possible, and it should be free from drafts. In a properly ventilated barn, the ventilation system should provide 60 cubic feet per minute (cfm) for each 1,000 lb of horse in winter and 160 cfm per 1,000 lb of horse in summer. In summer, satisfactory ventilation usually can be achieved by opening barn doors and by installing hinged walls or panels near the ceiling that swing open.

Requisites of horse barns

Whether a new horse layout is built or an old one is altered, all buildings, fences, corrals, and trees should be placed according to a master plan, for once established, they usually are difficult and expensive to move. The arrangement should make the best possible use of land and should require little walking by attendants when caring for horses.

All horse barns should meet the following requisites.

Accessibility Barns should be on an all-weather roadway or lane to facilitate the use of horses,

delivery of feed and bedding, and removal of manure.

Dryness Barns should be on high ground so water will drain away from them.

Expandable design Barns should be designed so they are easy to expand if and when the time comes. Often a building can be lengthened provided no other structures or utilities interfere.

Water and electricity Water and electricity should be available and convenient to use.

Controlled environment Barns should be built to modify winter and summer temperatures; maintain acceptable humidity and ventilation; minimize stress on the horses' nerves; and protect horses from rain, snow, sun, and wind.

Reasonable cost Initial cost is important but durability and maintenance should be considered, as well as such intangible values as pride and satisfaction in the buildings and advertising value.

Adequate space Too little space may jeopardize the health and well-being of horses, but too much space means unnecessary expense.

Storage areas Storage space for feed, bedding, and tack should be provided in the building where they are used.

Attractiveness An attractive horse barn increases the sale value of the property. A horse barn will have aesthetic value if it has good proportions and is in harmony with the natural surroundings.

Minimum fire risk The use of fire-resistant materials gives added protection to horses. Also, fire-retarding paints and sprays may be used.

Safety Projections that might injure horses should be removed. Feeding and watering equipment should be arranged so attendants need not walk behind horses.

TABLE 1 Horse Fences

Post and fencing material	Post length and diameter	Size of rails, boards, or poles and gage of wire	Fence height	Number of rails, boards, or poles and mesh of wire	Distance between posts on centers
			<i>Inches</i>		<i>Feet</i>
Steel or aluminum posts and rails. ¹	7½ ft -----	10 or 20 ft. long -----	60	3 rails -----	10
	7½ ft -----	10 or 20 ft. long -----	60	4 rails -----	10
	8½ ft -----	10 or 20 ft. long -----	72	4 rails -----	10
Wooden posts and boards.	7½ ft.; 4 to 8 in ----	2 x 6 or 2 x 8 in. boards ----	60	4 boards -----	8
	8½ ft.; 4 to 8 in ----	2 x 6 or 2 x 8 in. boards ----	72	5 boards -----	8
Wooden posts and poles.	7½ ft.; 4 to 8 in ----	4 to 6 in. diameter -----	60	4 poles -----	8
	8½ ft.; 4 to 8 in ----	4 to 6 in. diameter -----	72	5 poles -----	8
Wooden posts and woven wire. ²	7½ ft.; 4 to 8 in ----	9 or 11 gage staywire -----	55 to 58	12-in. mesh -----	12

¹ Because of the strength of most metal, fewer rails and posts are necessary than when wood is used.

² Use 1 or 2 strands of barbed wire—with barbs 3 to 4 inches apart—on top of the fence.

HORSE BARNs

Labor-saving construction This requisite is a must in any commercial horse establishment. Also, where horses are kept for pleasure, unnecessary labor should be eliminated in feeding, cleaning, and handling.

Healthful living conditions Healthy horses are better performers; therefore, barns should be easy to keep clean so they will provide healthful living conditions.

Rodent and bird control Feed and tack storage areas should be rodent- and bird-proof.

Suitable corrals and paddocks Horse barns should have well-drained, safe, fenced corrals or paddocks adjacent to them. If this is not possible, the corral or paddock should be nearby.

FEED AND WATER EQUIPMENT

The design of feed and water equipment should fill the basic need for simple and effective equip-

ment with which to provide hay, concentrates, minerals, and water without waste or hazard to the horse. Whenever possible, for convenience and safety, feed and water equipment should be located so it can be filled without the caretaker entering the stall or corral.

Feed and water equipment may be built-in or detached. Because specialty feed and water equipment is more sanitary, flexible, and suitable, many horsemen favor it over old-style wood mangers and concrete or steel tanks. Bulk-tank feed storage may be used to advantage on large horse establishments to eliminate sacks, lessen rodent and bird problems, and make it possible to obtain feed at lower prices by ordering large amounts.

FENCES FOR HORSES

Good fences (1) maintain boundaries, (2) make horse training and other operations possible, (3) reduce losses to both animals and crops, (4) increase property values, (5) promote better relationships between neighbors, (6) lessen the likeli-

hood of car accidents from animals getting on roads, and (7) add to the attractiveness and distinctiveness of the premises.

Large pastures in which the concentration of horses is not too great may be fenced with woven wire. The mesh of the woven wire fence should be small so horses cannot get their feet through it. Corrals, paddocks, and small pastures require stronger materials. The deficiencies of board and pole fences are: They must be kept painted; they splinter, break, and rot; and they are chewed by horses.

Until recently, conventional metal fences of steel, aluminum, wrought iron, chain link, or cable had one or more deficiencies. But metal fences have greatly improved in recent years.

Table 1 lists the materials and specifications commonly used for horse fences.

By PETER C. SMITH, Associate of the Royal Institute of British Architects

Reasons for the Provision of Stables

Before considering the planning and construction of stables in detail, a greater appreciation of the fundamental requirements might be gained by considering briefly the reasons for providing stables. A horse living out in its natural surroundings has no need of protection from the weather providing it has a sufficiency of good food. The thickness of the coat during the winter months, the natural oils in the skin and the fact that the animal may move about freely, are all adequate protection from inclement conditions. A horse living under such conditions, however, is fit only for the lightest work.

A horse in full work needs to be fit and to be kept clean. To obtain this condition requires the removal of surplus fat, a clipped coat and regular grooming. Thus not only is the coat lightened but cleaning and grooming take away a large proportion of its natural protective oils. A horse in this condition cannot satisfactorily live out and artificial methods of protection must be provided, by means of blankets and stables. Stables have, therefore, to provide to a great extent the protection to the animal which has been removed by the requirements of work and cleanliness.

Individual Requirements of Stable Buildings

It must be appreciated that the requirements of no two owners will be the same. Discounting the differences in sizes and accommodation needs of the various establishments and the purpose to which they may be put, it will be found that many owners have fixed ideas on the running of their stables which may materially affect the design. It is important therefore to discuss with the owner, not only his accommodation needs but his routine to be carried out daily. Information on the furnishing needs of each unit will also be required.

Many stables will be erected as an adjunct to an existing house and the accommodation of the buildings will depend on the ancillary accommodation for both staff and storage already available on the site. If the buildings are to be erected in conjunction with a new house, full staff and storage accommodation may be needed within the stable buildings. The provision of storage will also depend and vary on the method of running the stables; if for instance they are to be attached to a farm, the farmer might grow his own hay and leave it in the stacks to be cut as required. In such a case the provision of a hay store would not be necessary or would be of minimum size, say enough for one or at the most two weeks supply.

Staff accommodation will vary enormously. Most large establishments will have some staff living in and the provision of bed-sitting rooms or flatlets may be needed. Many small establishments are run by the client and his family, with help from local girls who will travel to and from the stables each day. Small establishments will seldom require any staff accommo-

dation as the grooms will either be working in the stables or exercising the horses during the working day. When staff accommodation is required it should, preferably, be placed near to the stable buildings.

Principal Requirements of Stables

The basic needs controlling the design and construction of stable buildings may be enumerated as follows:

1. Dryness
2. Warmth
3. Adequate ventilation but with freedom from draughts
4. Good drainage
5. Good lighting, both daylight and artificial
6. Adequate and suitable water supply

Siting of Stables

Consideration must first be given to the ground upon which the stables are to be constructed. Ideally the ground should be naturally well drained, i.e. chalk or gravel, and should drain away from the buildings. Clay, which retains water, is unsuitable and if stables have to be erected on such land the water holding capacity of the site must be broken down and the water dispersed by drainage.

The buildings containing the horses must be protected from northerly or easterly winds. The doors and windows of the boxes or stalls should therefore face in a southerly direction. On a confined site this aspect may not be obtainable in which case protection must be afforded by other buildings or a belt of suitable trees.

Protection should also be made against the prevailing wind of the area blowing directly into doors and windows. Consideration of the prevailing wind, however, must be related to each individual site, as the contours of the landscape surrounding the site and the relationship of the site to woods, buildings, etc., will have a direct bearing on the effect of the wind upon that site. Therefore get to know the site conditions and plan accordingly.

Although protection from the winds is necessary, there should be a free circulation of air around the stables, so a site hemmed in by trees and buildings is quite unsuitable. Avoid siting the buildings on top of a hill or in any other very exposed position. To the opposite extreme, avoid hollows which catch the water and are invariably frost pockets during the winter months.

Stable buildings should be positioned well away from adjoining houses, and there is little doubt that most local authorities will insist on this requirement as a condition of their consent.

Ease of access to the stables is usually an important consideration with owners who look after their own animals, with only daily help. This will be appreciated by anyone who has had a sick animal in stables, requiring frequent visits during the day and night. Care must be taken, in these circumstances, to ensure that the prevailing wind does not carry the smells of the stable into any part of the house. Even

the most enthusiastic horse owner will object to the smells of his stable yard being carried into his drawing room.

Layout and the Main Requirements of the Stable Group

The units making up the whole of the stable buildings will vary not only in relationship to the size of the establishment but also to the needs of the owner. The requirements for a stable to accommodate, say, 20 horses without any existing ancillary buildings and allowing for a staff of five grooms living out or at least separately accommodated will be as follows:

1. Twenty loose boxes
- *2. One sick box
3. Feed room
4. Hay store
5. Straw store or storage for alternative litter
6. Feed store
- *7. Washing and cleaning room, incorporating drying facilities
8. Saddle and bridle room (tack room)
9. Utility box or boxes depending on the organization of the stable
- *10. Litter drying shed
11. Manure bunkers
- *12. Office, in some cases only
13. Lavatory accommodation
- *14. Sitting-room for grooms
- *15. Garage or covered area for motor horse box and/or trailer

In many cases this accommodation will be reduced by the omission of those items marked *, particularly in small establishments.

The relationship of the various units must be carefully considered both in respect of relationship to each other and to the site and surrounding buildings. A groom should be allowed to concentrate his energies on the horses and not be unnecessarily taxed by the necessity to carry bales of hay and straw and sacks of feed great distances. Even in these days of mechanization there are few stables, particularly small ones, which can afford to install expensive handling equipment. Care must therefore be taken to minimize the handling of heavy materials and a lot can be done in this respect by careful planning.

Layout of the Loose Boxes and Stalls

First consideration must be given to the layout of the loose boxes and stalls; but before proceeding with the design, the detailed planning requirements of the client must first be ascertained. Most clients will require loose boxes for both horses and ponies, but some may want stalls or a proportion of each. Stalls are seldom used nowadays and many existing buildings containing stalls are being converted to loose box accommodation. Stalls have many disadvantages as compared to loose boxes, their only advantages being in economy of construction and labor.

For design requirements, 12 by 12 ft may be taken as a suitable size for each loose box. This size will comfortably house a 16.0-17.0 hh. hunter. Ponies may require a lesser size, but it

HORSE STABLES

is felt unwise to reduce a box below 10 by 10 ft, a pony's box today may need to serve for a horse tomorrow. Stalls should be a minimum of 6 ft wide and 9 to 10 ft long.

The basic layout of the buildings containing the boxes will depend on economic considerations as well as on site conditions. It is probably true to say that most stables erected at the present time consist of a simple line of boxes, each opening directly into the open air, as shown in Figs. 1 and 2.

This is the simplest form of layout and quite practical. Depending on the number of boxes needed, they may be extended around a yard or a number of yards. The detail can be improved by extending the roof to give an overhang along the open side. This gives a covered walk and helps to protect the horses and grooms from rain and excessive sunlight.

It will thus be possible to carry out most of the work affecting the boxes under cover from the elements. This covered way should be extended to connect to the adjoining buildings of the group. Avoid supporting posts as these can form a hazard.

A more expensive layout is to have the boxes inside a building with the adjacent passage contained within the curtilage of the external walls, as shown in Fig. 3.

This layout is often found in the more elaborate layouts built during the last century. Ancillary buildings should be built so that they connect to the stables internally throughout the whole range, subject to the conditions imposed by fire precautions. The advantages of designing in this manner are that:

1. The ventilation of the building may be better controlled and draughts thus reduced to a minimum. A suitable form of mechanical ventilation may be installed.
2. Work may be carried out under better conditions and with greater comfort.
3. Easier maintenance of warmth.
4. Quieter than open stabling, which can be an important factor where stables are built near to main roads, railways, or in other areas with a high noise level.

Where site conditions are restricted, the boxes may be double banked as shown in Fig. 4 or more economically with a central passage as shown in Fig. 5.

It will be appreciated that there are many possible variations in layout which can be incorporated in the design to satisfy the needs of the client and site conditions while at all times conforming to the basic requirements of each unit.

Utility Box

In all stables, of whatever size, it is an advantage to provide, for the want of a better name, a "utility" box. Such a box may be used for a variety of purposes, clipping, grooming, shoeing, washing, and the treatment of cuts, etc. Small establishments of the type illustrated in Fig. 6 may need only one, larger establishments more. Figure 7 shows an arrangement which may be used with advantage in all establishments, irrespective of size. In this establishment the management was based on one groom to three horses and a utility box has been provided for the use of each groom. In this box all the various activities mentioned above, are carried out with greater efficiency and cleanliness.

The box, on the basis shown (ratio 1:3), need not be larger than the normal loose box. When, however, it is provided for a greater ratio it should be related to the number of horses likely to be accommodated within it at one time.

Fig. 1 Loose box.

Fig. 2 Section.

Fig. 3

Fig. 4

Fig. 5

The eventual size must therefore be discussed and agreed with the client. Its position should be as near as possible central to the group of loose boxes it serves.

Sick Box

At least one sick box is essential in large establishments and it is obviously of great advantage to include one in the plans of even small stables. In the main it is intended for the accommodation of an animal suffering from an infectious disease and therefore requiring to be isolated from other horses. It may in fact be used by any horse needing quiet and possibly specialized treatment.

The box should be placed well away from the stables but, as a sick animal requires to be visited more often than a healthy one, the position must be related to the convenience of those in charge of him. If possible, place it in such a position that although isolated the horse can see the other horses. Remember that horses are gregarious animals, so the patient will be happier and probably make a quicker recovery if he does not feel completely isolated from the world.

The box should be bigger than the usual box by about 50 percent. It would be wise at this planning stage to remember that the roof must be made sufficiently strong to support a sling attachment.

Feed Room

The feed room is intended to house the bins containing the feed for daily use, as opposed to the feed store which will contain the sacks of food or the containers if bulk storage is used. In small establishments it might combine with the feed store or in fact be formed as a recess out of the stable building, though this minimum arrangement is not recommended. The size will depend not only on the number of horses it serves but also on the client's arrangements for buying feed. A farmer might grow his own and, for instance, send sufficient for a week's supply across to the room from his main store, after carrying out any treatment needed. Some clients who buy from merchants will have regular weekly or fortnightly deliveries.

It is in this room that the feeds are prepared each day and it must be positioned close to and preferably directly connected with the loose boxes.

The equipment to be contained in the feed room consists of separate bins for oats, bran, barley, nuts, chaff, etc. (the bin requirements will depend on the method of feeding the horses and will often vary from one establishment to another); a sink provided with hot and cold water; a bucket filling tap to each service; and wall racks on which to hang sieves, measures, brooms, and buckets. Few small establishments will install machinery for bruising oats, chaff cutting, etc., but large establishments may require these machines, and if so allowance must be made for them in the design. Most merchants nowadays will carry out any processing required before delivery, so the need for machinery will be rare.

Feed Store

This store should open directly into the feed room and the storage areas for hay and straw should adjoin it. The necessity for this room will depend on the supply factors mentioned in the last paragraph dealing with the feed room. Many small establishments will not need

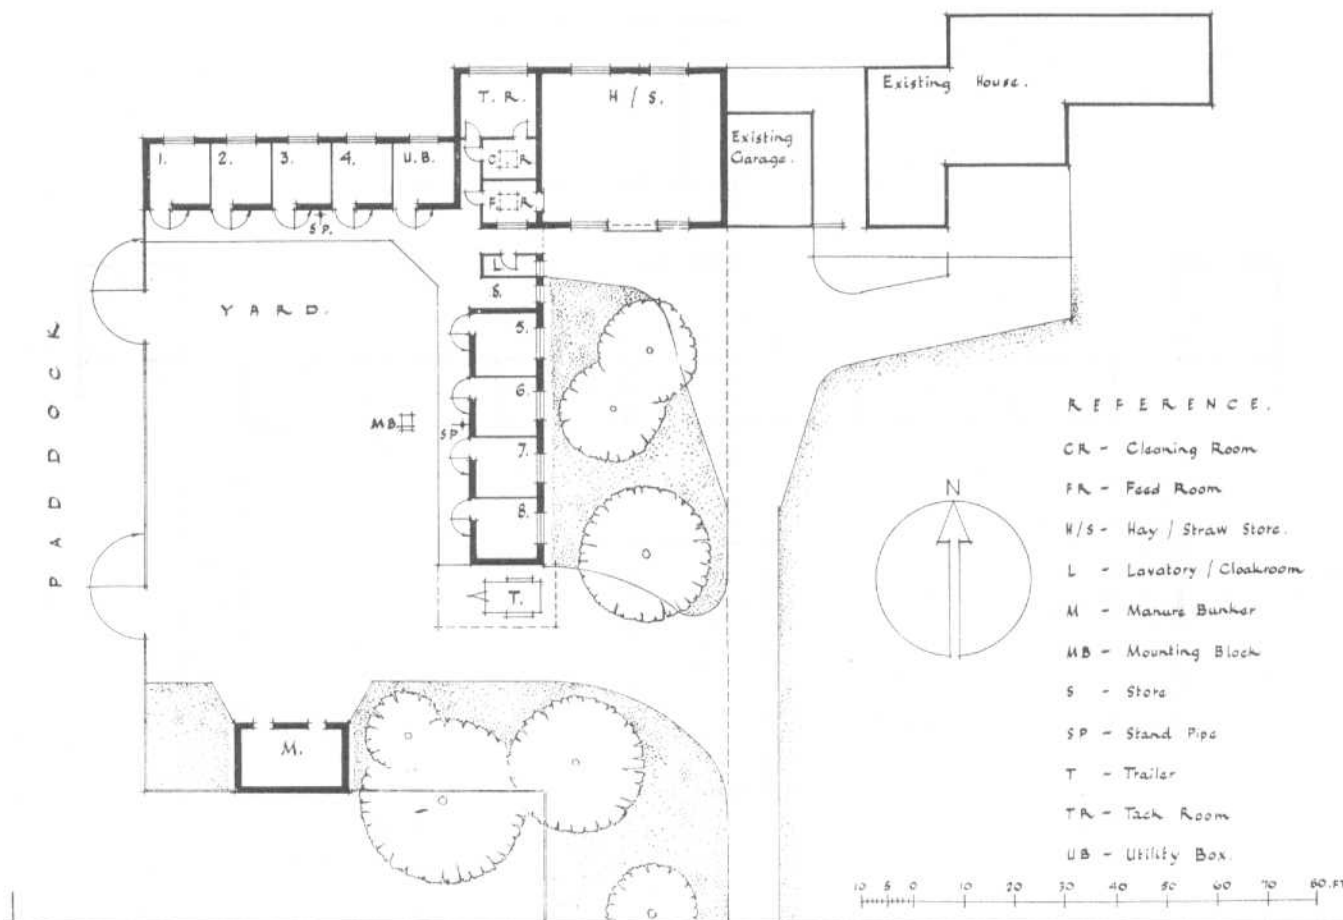

Fig. 6

a separate store and will combine the feed store, with easy access to the feed room and to the loose boxes. Hay nets will generally be filled in the hay store and then be taken direct to the boxes. If hay racks are fitted, the bales will then be taken direct to the boxes before breaking and dividing into the racks. Straw will be required at the boxes baled, and the bales are then broken before dividing between the boxes and spread to form the beds. Small quantities of hay and sometimes straw will be required in the feed room, but most will be taken direct to the loose boxes.

Hay and Straw Stores

The stores should be situated next to the feed store, with easy access to the feed room and to the loose boxes. Hay nets will generally be filled in the hay store and then be taken direct to the boxes. If hay racks are fitted, the bales will then be taken direct to the boxes before breaking and dividing into the racks. Straw will be required at the boxes baled, and the bales are then broken before dividing between the boxes and spread to form the beds. Small quantities of hay and sometimes straw will be required in the feed room, but most will be taken direct to the loose boxes.

Storage for Other Forms of Material Used as Litter

So far only straw has been considered for use as litter. There are many other materials used, many being individual to certain parts of the country where local supplies are available. The storage of these alternative materials must be considered.

These main alternatives may be enumerated as follows:

1. Fern leaves

2. Fir needles
3. Peat
4. Sand (not sea sand)
5. Sawdust
6. Wood shavings

In some cases combinations of these materials are used, i.e., sawdust and peat.

The main essentials for the storage of any of these materials are the same as discussed for straw. They must be kept in a dry and well ventilated building. Peat is usually stored either in bales or in bulk and sawdust and wood shavings in sacks. Fern leaves and fir needles are generally stacked in bulk and require to be frequently turned.

Saddle and Bridle Room

This room, now more generally referred to as the tack room, should be positioned close to and preferably directly connected to the loose boxes under cover. In a large layout more than one room may be required (see Fig. 8).

The size will depend on the number of horses it serves and to the purposes for which those horses are used. The needs will vary from one establishment to another but the client should be able to give the necessary information to the architect for his present and possible future needs.

The layout requirements of the client will

also affect the size of the room. Some like the tack of each horse grouped together, others prefer to separate their saddles, bridles, girths, etc.

In addition to the storage of tack this room usually accommodates the medicine cabinet and poison cupboard.

In some establishments a bit case may be required, the size will be dependent on the number, types and sizes of the bits to be stored.

Chests for clean blankets, sheets and other clean clothing are usually provided in the tack room. These may be formed as built-in chests or standard chests may be obtained and space for them along the walls allowed.

This description of the requirements of the tack room has assumed throughout that a separate washing and cleaning room will be provided. In most establishments the tack room will be required to serve both purposes, in which case the fittings and services discussed below must be incorporated in the tack room.

Washing and Cleaning Room

It is of considerable advantage to provide this room in any establishment, however small. It should open directly out of the tack room and have an external door off the stable yard so that all dirty tack, etc., may be taken into it without

Miscellaneous

HORSE STABLES

Fig. 7

the necessity of passing through the tack room.

It should be fitted with a large and deep sink or sinks, depending on size, and each sink should be provided with a constant supply of hot and cold water. Facilities may be required for washing and drying blankets, sheets, and other clothing.

Saddle room horses will also be needed. The client may have these, in which case they must be measured and due allowance made for them. If new ones are allowed for, the size required should be agreed with the client and details obtained from the proposed manufacturer.

Bridle cleaning holders will also be required. These are suspended in suitable positions from the ceiling and may be of either a fixed length or of a telescopic type. Each must be fixed in such a position that a clear area all round is allowed for cleaning purposes.

The only other items required in this room are suitable cupboards and drawers in which to store the cleaning materials.

Manure Bunkers

The storage provision for manure must be positioned well away from the area of the loose boxes but will require to be easily accessible from them. It must be adjacent to a road or drive to facilitate collection.

The usual formation is of open bunkers, and

such an arrangement is quite satisfactory. The size and cubic content of the bunkers will depend not only on the number of horses accommodated but also on the routine which each individual stable will follow regarding the disposal of the manure. Some establishments will have contracts for weekly collection or even at lesser intervals. Stables attached to farms will often deposit the manure daily at the permanent stacks or in pits so that it may be allowed to rot down and be used by the farmer on his own land when required.

Weighing Machine

A weighing platform will sometimes be required particularly in large establishments. The weighing machine should be positioned at the entrance to the stables, preferably next to the office.

Office

Large establishments and most riding schools will require an office for the manager. In most cases it will require to accommodate a desk, chairs, filing cabinets and stationery cupboard. A room of about 100 to 150 sq ft will be ample in most cases. A telephone, which should be fitted with external bells, will be required.

The office should be positioned to command

good supervision over the stable yard and over the delivery of goods. In riding schools supervision over riders passing in and out of the yard must be allowed for.

Mounting Block

Most stables will require a mounting block. This should be positioned at the side of the stable yard but should not obstruct the free use of paths or drives. A horse is mounted from the near side and there should be adequate free space to be able to lead the horse up to it in a straight line and ride off in a straight line after mounting. No horse will stand still to be mounted if its nose or tail is close to an obstruction.

Fences and Gates

Fencing and gates adjacent to or surrounding the stable yard and those surrounding paddocks should be of stout construction. The more usual type of fencing is post and rail. Gates should have a clear opening of at least 10 ft (12 ft is better) and hand gates should be 4 ft clear opening to allow the easy passage of horse and rider.

Gates will frequently be used by mounted riders so they should be fitted with hunting latches to facilitate opening.

Fig. 8 Tack room.

Fig. 9 Detail of loose box.

Accommodation for Motor Boxes and Trailers

Most small stables will require accommodation for one trailer and many will own their own motor box. Provision may be required for these vehicles, either by a completely enclosed building, or by an open sided shelter. Normal garage provision should be made, though large establishments with more than one motor box may require a workshop for a mechanic and an inspection pit. Often repairs will be carried out at the local garage.

Ensure that there is adequate space for turning, for lowering ramps both side and rear, and for loading and unloading the horses. As mentioned in the case of the mounting block a horse should be brought up to the ramp in a straight line, and plenty of space should be allowed, both to ensure this and to deal with cases of horses difficult to box.

Staff Accommodation

Few small establishments will require accommodation for staff. Where the stables are close to the client's house facilities are often provided within the house itself.

In large establishments some permanent living-in staff are usually employed.

Lavatory accommodation will be required in most schemes, and if the establishment is likely to be used by the public, provision should be made for both sexes. The larger riding schools may in addition require changing and shower rooms for use by their clients.

Residential riding schools should have accommodation for both clients and staff convenient to the stables.

Loose Boxes

For the requirements of the sketch plan the size of the box was given as 12 by 12 ft. This size is adequate, but may be increased up to 16 by 16 ft. It need not be increased beyond these dimensions, except in the case of a sick box. Some clients may favor a box of rectangular shape, of say 16 by 10 ft, in which case the bedding will be positioned to cover the area well away from the external door (Fig. 9).

Stable Furniture and Services

Each box or stall will require the following items of furniture and services:

1. Manger
2. Hay rack or ring for hay net
3. Provision for water

4. Rings for tying up
5. Salt lick holder
6. Electric lighting point
7. Electric power point

Manger

The manger is a container for the horse's feed, is usually of metal, and should be fixed to the wall of the box at a height of about 3 ft from the floor. Standard mangers may be obtained constructed of galvanized steel, vitreous enamel, earthenware or stainless steel; they are designed to fit along the face of a wall or in the corner. The latter material is recommended, although expensive, but the eventual decision will depend on the clients' requirements and economic considerations. Mangers may be obtained combined with either a hay rack or a water trough. Those combined with a water trough are not recommended as they allow a horse to feed and drink at the same time. This practice is not good for the animal's digestion and at the same time usually results in fouling the water.

The usual position for the manger is on the far wall from the door. Before deciding if this position is the best it is proposed to consider the consequence of fixing the manger to alter-

HORSE STABLES

nate walls. In the first place remember that the stables are designed to accommodate horses of varying types and tempers; not only is the comfort and safety of the horse to be considered but also the safety and convenience of the staff.

Hay Rack

Hay racks may be combined with the manger or may be separate racks which should be securely fixed to the wall. Standard racks may be obtained of suitable sizes and types. The position of the rack and its height should be agreed with the client as there are essentially two schools of thought on this subject. One school maintains that it should be at low level, the horse thereby eating as near as possible

in its natural position, and the second school prefers the rack at high level, about 5 ft to the top from floor level. Five foot is recommended as a maximum height (1) to facilitate filling the rack and (2) to prevent dust and seeds getting into the horse's eyes while feeding.

Provision of Water

Horses must be provided with adequate fresh and clean water at all times. The commonest method is to provide it in a bucket. An alternative is to fit a 2-gal automatic drinking trough.

Rings

Rings will be required for both boxes and stalls for tying up and in some cases for supporting

the hay nets. Two rings per box or stall are generally considered to be adequate; if hay racks are used, one will often be sufficient.

Rings for tying up should be fixed at about 5 ft to 5 ft 6 in. high; one should be positioned close to the hay rack or hay net folder or ring. This will enable the horse to eat its hay while being cleaned or treated.

Salt Lick Holder

Many owners like to have a block of salt permanently available for each horse to lick, and suitable containers may be obtained for the special blocks which are manufactured for this purpose. The holder should be fitted over or to one side of the manger and at a height of about 5 ft.

By PETER C. SMITH, Associate of the Royal Institute of British Architects

This building is intended for use for schooling horses and riders either during inclement weather or when it is considered necessary to keep distractions to a minimum and thus allow horse or rider or both to concentrate with greater ease on the lesson in hand. This requirement is of particular importance when schooling either young horses or novice riders.

Due to the size of the building, it should be sited on level ground which should be well drained.

The size of the school will depend upon the needs of the client. A full-size military school measures 60 by 180 ft. This allows for three rides to be instructed at the same time, each working within a square of 60 by 60 ft. Although the individual clients' ideas may vary in respect of their own requirements, it is not recommended that this span be reduced, as it allows suitable space to longe a horse at the full length of a longeing rein, which measures 25 ft in length. An alternative size which may be in more demand nowadays is 66 by 132 ft (20 m by 40 m) which is the size of a dressage arena. (See Fig. 1.)

The lower parts of the walls on all four sides up to a minimum height of 4 ft should be of stout construction able to withstand rough usage and kicking. At the same time it must be sloped as shown, at an angle of about 12 to 15°, thus this splay must be formed to prevent either horse or rider from rubbing or knocking himself against the walls when using the outside track close to the walls. The splay will also prevent a horse from rubbing a rider off or damaging his knees. This lower section must therefore be lined through, clear of all posts, piers or other projections, and must be continuous and unbroken throughout the length and width of the school. This part of the wall is often constructed of stout timber or of steel framing and faced on the school side with matched boarding.

This building requires good natural lighting with an even distribution of light over the full area of the floor.

The floor may be formed by a number of methods. One method is to excavate the area within the external walls to a depth of 24 in. and fill to a depth of 18 in. with birch or hazel faggots tightly packed. The final 6 in. is then filled with tan. The tan will require to be made up from time to time as it shakes down in the interstices of the faggots. (See Fig. 2.)

An alternative to the use of tan is sawdust. This has the advantage of not "balling" in the horses feet, which is one of the disadvantages of tan. Another disadvantage of tan is that if retained and left in the horse's feet it can cause them to heat. The main disadvantage of sawdust and wood shavings is the danger of fire. Peat is probably a more satisfactory finish than either of the foregoing materials and forms a very satisfactory floor.

The floor will at times require to be damped. The most economical method of carrying out this operation is to provide a standpipe adja-

Fig. 1

Fig. 2

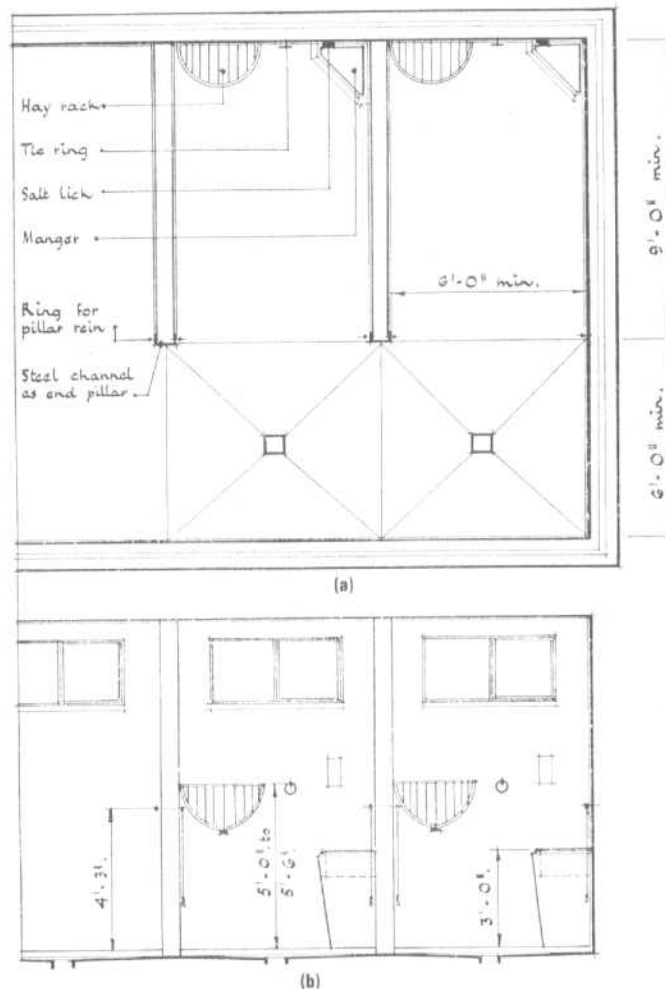

Fig. 3 Stalls. (a) Plan; (b) elevation.

cent to the building so that a hose fitted with a fine spray may be used or a lawn sprinkler fitted. If economic considerations are not too severe, a system of fine shower spray may be fitted beneath the ceiling in such a manner that the sprays give an even distribution of water over the floor. If such a system is fitted, ensure that any exposed pipes at low level are adequately protected, as detailed for low-level pipes in the boxes. It will also be necessary to provide protection against freezing to both pipes and fittings.

The entrance or entrances to the school will depend on site conditions, size, and the needs of the client. If a full-size school of 60 by 180 ft is designed for instructional purposes, three doors may be considered desirable, one to each sever of the building. A school likely to be used for dressage tests will require a door in the center of one end wall and a second either

at the far end or at the far side of the right-hand wall. This arrangement allows the rider to enter the arena and leave the arena at the correct points.

Entrance doors should be of adequate height to allow a rider to enter while mounted. A minimum height of 10 ft is recommended and a minimum width of 8 ft. Sliding doors are often used and these are satisfactory providing care is taken in choosing a suitable type of gearing. Handles should be fitted both externally and internally, one at about 4 ft high for operation from ground level and one at about 7 ft for use by a mounted rider.

Many schools have a gallery formed along one side of the main side walls for viewing, or along both walls. The requirements in respect of such a gallery should be discussed with the client and his full needs ascertained early in the job.

The outstanding need is that of siting in relationship to the main stable group. The building should be placed in a convenient position to the loose boxes but should be separated from them to prevent horses in the boxes from hearing the work proceeding in the school. Horses at rest very often get upset if the school is placed close to them so that they can hear either the voice of command or the horses at work. The building should also be positioned adjoining and easily accessible from schooling paddocks as it will be used as an extension of these paddocks. A road or paths should connect it to both boxes and paddocks. A school with natural lighting by means of roof lights may be oriented in any direction, but one with windows along the sides should preferably be sited due north and south longitudinally. (See Fig. 3.)

By RICHARD U. N. GAMBRILL and JAMES MACKENZIE

In general the kennel should be built on a site where the ground drains well, with proper protection from cold winter winds and with the possibility of a cooling breeze in summer. A few large shade trees around the kennel are really a necessity.

If possible a kennel should not be built where the neighbors can be annoyed by barking at night.

There are two main parts to this kind of kennel, the compartments where the dogs live, and the workroom where the food is prepared and the dogs are washed and trimmed up.

The Workroom

This should contain a stove, hot and cold water and a sink. There should also be suitable bins or closets for the feed and the bedding, and a large and well-stocked medicine closet.

It is best to have a floor that can be washed down thoroughly every day, with a drain in the middle. A large solid table is generally necessary in most kennels on which to place the dogs for trimming, stripping, etc.

There should be a washtub in the workroom with a division in the middle to wash dogs and rinse them afterwards. This is always useful in all kennels for every purpose. If raw meat is used, a refrigerator will be found invaluable, also a meat chopper to mince up the meat. Many small kennels use one of the many varieties of canned meat on the market, and these are most satisfactory and economical in the long run.

Compartments

The size of the compartments or living quarters for the dogs depends, of course, entirely on the kind of animal kept. For the sake of convenience in these plans, a compartment 5 ft square is used in every case; but this, of course, can be altered with ease and without in any way spoiling the plans. The larger the space the more comfortable for the dog, and the more room he has to exercise, but this need not be carried to excess as he is supposed to be given proper exercise outdoors. A room 5 ft square will be sufficient for any kind up to the size of setters, particularly if only one dog is to be kept in each room.

Each lodging room should lead into a small concrete yard, into which the dog can run at any time, and all these concrete yards should open into a large grass yard where the dogs can be exercised together if advisable or separately when necessary. This, of course, entails the question of fighting, and that is a matter of kennel discipline for the owner to decide himself.

Kennel Layout

The plan in Fig. 1 represents a very simple kennel with four compartments. It is useful to have a small kennel of this size near one's house in which to keep house dogs when they

are ill, or to raise a few litters of puppies. It contains, as shown on the plan, a stove, two washtubs, a table and a bin for the feed. Each compartment opens into its own cement yard and all these yards open into a large grass yard beyond. These compartments are 5 ft square, which is large enough for any breed of dog up to a setter.

The plan in Fig. 2 represents a very useful arrangement for a private or commercial dog kennel. There is no limit to the number of compartments that can be built. If different breeds of dogs are kept, the compartments on one side can be larger than those on the other. Heat can be carried from the workroom into the living quarters. A solid partition can be put across the building below the fourth compartment. The first part would be heated and contain eight compartments for use as a hospital. The remaining compartments would have no heat. The workroom contains not only closets for bedding, feed and coal, but also a stove, sink, washtubs and table. A medicine closet

is, of course, an indispensable necessity and should be included in every kennel whether large or small.

The plan in Fig. 3 represents a somewhat different arrangement of a dog kennel. The workroom is placed at the rear with an open passageway between it and the main part of the kennels. By leaving open the doors at either end of this passageway, a free current of air is allowed to pass through at all times, which prevents smells from circulating through the kennels. Two large closets have been provided for bedding and feed. One wing of compartments should undoubtedly be heated for use as a hospital. If this cannot be done conveniently from the boiler in the workroom, a small heater can be installed in the wing itself. This plan can be limitless in size, the only disadvantage being that the compartments on the north side have not been supplied with cement yards because of the cold in wintertime. These compartments, however, can always be used for whelping pens.

KENNELS

Fig. 2

Fig. 3

NATURE CENTER

The modern nature center:

- May exhibit a representative sample of such indigenous cold-blooded animals as snakes, turtles, fish, or amphibians but generally avoids warm-blooded animals because of the care they require and the excessive expense of maintaining them properly. Most centers stress the importance of observing wild creatures in their native habitats.
- Avoids large and expensive dioramas normally found in the traditional museum and favors simple, inexpensive, readily changeable displays which invite visitors to see, handle, smell, or listen—displays they can become directly involved with.
- Has areas inside its interpretive building designated as classrooms. Compared with an ordinary school classroom, they are quite informal in design and use. Basically, they are intended to orient visitors—the philosophy at most centers being that the outdoors is the primary classroom.
- Is designed for a wide variety of recreational

activities such as hiking, bird watching, and photography. But these activities are mainly passive ones and are not stressed or adequately budgeted for, although the situation may be otherwise in some public parks.

- Combines the policy elements of both park and resource management agencies. Many centers are zoned so that a percentage of the land base is left natural while other sections are designated for habitat manipulation—controlled burning, mowing, tree planting, and harvesting. Each area serves to demonstrate the responses of nature when left alone or "managed" by man.
- Is staffed by professional naturalists and highly qualified amateurs whose job it is to develop, present, and administer the various programs offered at the center.
- Extends its services to a broad cross-section of the community by scheduling activities away from the nature center proper. These may include regular radio and TV appearances, articles in newspapers, seminars for middle management business executives, workshops for teachers and natural resource managers, guest lectures, or testifying on local or regional environmental issues. The influence of the modern nature center extends beyond the nature center itself.

The Components

The Nature Center Planning Division of the National Audubon Society believes that a nature center must have four basic components to function effectively:

- *An adequate natural resource base* representing a broad diversity of natural habitats. This may require as little as twenty acres or as many as hundreds of acres.
- *Physical facilities*, including roads, trails, indoor and outdoor displays, a maintenance building, equipment, and an interpretive building.
- *Programs*, which should be varied, inspirational, instructional, and recreational in scope.
- *And people*, including a staff of professional and volunteer teacher-naturalists, administrative and maintenance personnel, and the visiting public.

THE INTERPRETIVE BUILDING

The interpretive building functions as the focal point for administrative and program activities at the nature center. A stop here will help to orient visitors and make them aware of what the center has to offer.

The design of the interpretive building should be influenced by the programs envisaged for the

Guidelines for Interpretive Building Design, edited by Richard J. Manly, National Audubon Society, New York, 1977.

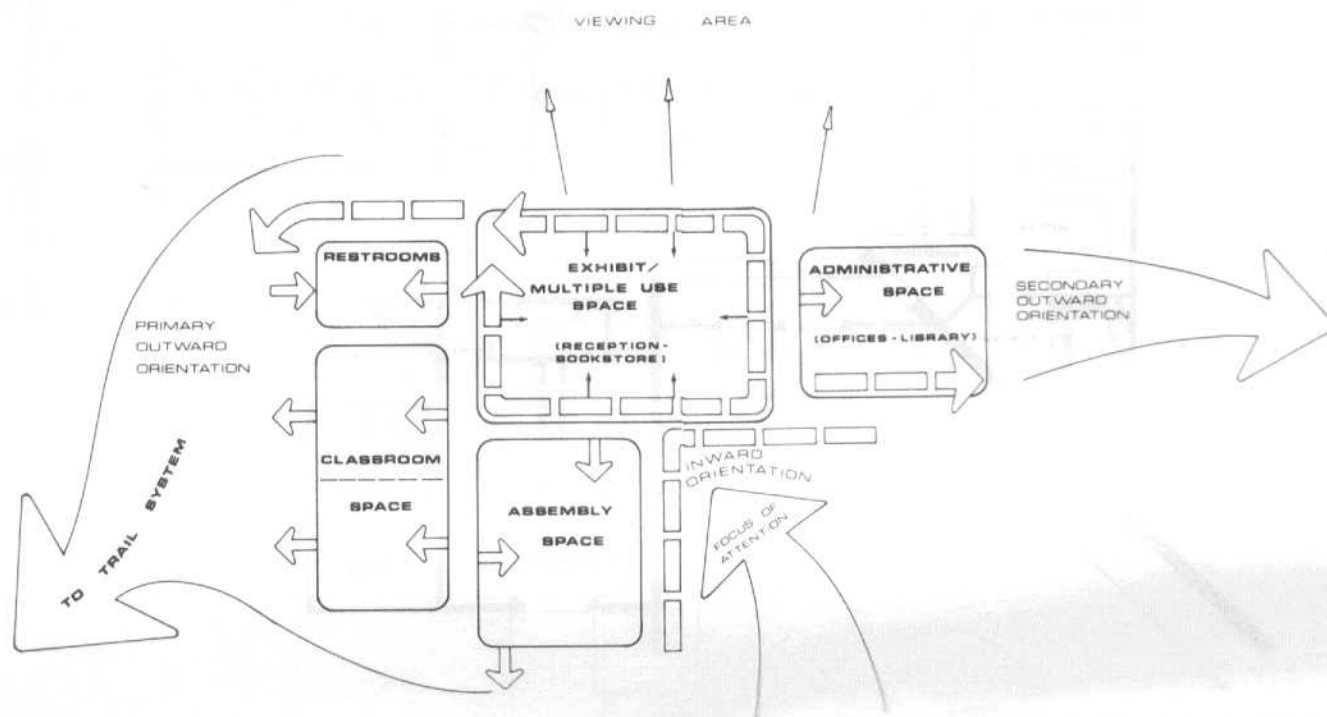

Fig. 1 Interpretive building design concept.

NATURE CENTER

nature center as well as by the physical and biological characteristics of the site.

The following are general guidelines for the siting and design of the interpretive building.

Building Site Locations

Certain basic criteria must be considered when determining the location of the interpretive building. These include:

- soil drainage and slope conditions favorable for construction
- access to the significant interpretive features at the nature center
- an esthetic setting
- avoiding biologically significant areas

- avoiding localized climatic extremes, such as frost pockets and exposure to high winds and drifting snow
- ample space to expand the building should expansion become necessary
- security from vandalism, fire, flooding, geologic faulting, and soil subsidence
- accessibility to existing roads and utilities.

Overall Building Design Considerations

- Top priority should be given to designing a functional and efficient structure. Some caution should be exercised so the interpretive building will not turn out to be an impractical architectural oddity.

- Entrances, exits, and interior spaces should be correlated with an overall traffic flow or circulation plan. Whenever possible, unsupervised groups or individuals should move through the building and over the grounds in a one-way pattern.
- The design should permit simultaneous use of the building by several groups.
- Low-profile buildings generally are less obtrusive visually than buildings with a high profile.
- The exterior of the building should be faced with wood or stone that will blend with the natural surroundings.
- Energy costs are mounting each year, and all efforts to minimize this expense should be incor-

Fig. 2 Cincinnati Nature Center, Sponsoring agency: Cincinnati Nature Center Association; Architect: Harry Hake and Partners, Architects and Planners, Cincinnati, Ohio 45206.

NATURE CENTER

porated in the design. The interpretive building should be a model facility for illustrating the conservation of energy. The following features should be considered:

- Siting the building where it will be protected from environmental extremes—high winds, frost pockets, full sun
- Thermal windows
- Efficient insulation
- Natural draft ventilation to minimize or eliminate the need for air conditioning
- Maximizing the use of natural lighting
- The development of alternative energy sources at the center by using solar, water, or wind power.

Interior Building Design Considerations

- The exhibit area in the interpretive building will be a central attraction for most of the visiting public. It should:
 - Have a flexible and efficient traffic flow pattern to provide easy access from the main building entrance, through the exhibits, and on to other key segments of the building or outside to the trail system.
 - Be provided with ample usable wall and floor space for exhibits and displays.
 - Be well lighted and ventilated.
 - Have a roomy and uncluttered appearance.
- Permanent staff members should have individual offices or work areas which afford them a reasonable degree of privacy. Additionally, many interpretive buildings have space allocated specifically for use by the volunteer staff.
- Centers that anticipate a large school attendance need several classrooms in the interpretive building. These rooms will provide space for orienting classes that arrive simultaneously before they move outdoors, and indoor activities can be held in them in case of inclement weather.
- If the nature center program will include activities for large audiences, an auditorium equipped with the necessities for lectures or audiovisual presentations will be required.
- Inadequate restroom facilities can cause undue program delays and foreshorten scheduled group activities. Therefore restrooms should be designed to accommodate peak visitor traffic to prevent such occurrences.
 - Access to the restrooms from outside the interpretive building should be provided for individuals or groups visiting the nature center after normal closing hours, when interior access will be impossible.
 - A reference library and reading room can be a great asset to the center's education program and, under certain situations, can serve as an auxiliary meeting room.
 - An important source of income for a nature center is a bookstore and specialty shop where visitors have the opportunity to purchase natural history books, field guides, checklists, bird feeders, and other items consistent with and useful to the outdoor education program. This feature should be located where it is readily accessible to visitors, yet it should not conflict with the internal traffic flow or be an audible distraction to anyone elsewhere in the building.
 - Some nature centers have wisely incorporated space for a "mud" or "wet" room in the basement of the interpretive building. There are a number of obvious advantages to this arrangement:
 - It provides a specific place for participants to clean up after a messy outdoor program.
 - It helps minimize janitorial problems.
 - It provides an additional storage area for program equipment, such as dip nets, snowshoes, and hip boots.
 - Work space for designing and building exhibits and displays is an absolute necessity. Because of noises, noxious smells, dust, and hazards from flammable materials, it is recommended that these activities be carried out in a separate maintenance building. If this is impossible, the work area should be located in a section of the interpretive building where it will not distract from the programs in progress or pose a safety or fire hazard.
 - Lack of adequate storage space seems to be a universal complaint about most interpretive buildings. Therefore, provision for plenty of storage space should be a prime concern in all planning and design phases.
- Some individuals think a photographic darkroom is an unnecessary frill in the interpretive building. Many nature centers, however, have built very exciting and successful nature photography programs around their darkrooms.
- If the interpretive building is going to successfully service a broad cross section of the community, it will have to be designed with the special requirements of small children, the aged, and the handicapped in mind. For example, ramps should be constructed in conjunction with or in lieu of stairways; special water fountains, sinks, and toilet fixtures should be installed; and exhibits should be built so they can be seen (touched, heard, and smelled, in some cases) by all visitors.
- Large windows can create a feeling of openness and intimacy with the outdoors. On the other hand, excessive and/or large windows:
 - Limit opportunities for wall displays.
 - Make darkening rooms for audiovisual programs difficult.
 - Raise the cost of heating and cooling if they are not thermally insulated.
 - Create a hazard to migrating birds, which have a tendency to crash into them and often are killed by the impact. (Attaching hawk silhouettes to individual window panes or hanging them loosely under the eaves of the roof will lessen this problem.)
- Modern carpets can withstand very heavy use, add a dimension of decorative warmth and, most importantly, muffle sounds. Carpets should be given priority as a floor covering in the exhibit area, auditorium, classrooms, and library.
- Electrical outlets and lighting fixtures often are neglected in the design of the interpretive building, only to later become a troublesome problem, particularly in the exhibit and classroom areas. Nowadays, many structures are being equipped with movable light fixtures installed on tracks mounted on the ceiling. Continuous-track electrical outlets also are available today and are preferred to standard fixtures.

- Youth treatment centers (Cont.):
 (See also Rehabilitation centers)
- Zoning and building codes, 71
- Zoos, 1158–1167
 animal exhibits, 1159, 1161–1164
 classification of, 1158, 1159
 grounds, 1160, 1161
 hospital-quarantine facilities, 1164
 maintenance of, 1164
 planning of, 1158–1163
 public services for, 1165

ABOUT THE BOOK

Now thoroughly revised, greatly expanded, and brought completely up to date, this is a basic reference source for design criteria for all major types of buildings. It offers a vast amount of working information on the essential component elements of each building type. In fact, it provides the functional relationships of these elements that will make a particular building successful.

Conveniently arranged in 11 major sections, this remarkable reference gives you...

- Thousands of separate entries covering the full range of questions likely to arise in planning or designing more than 100 major types of buildings
- All the basic design criteria you need for a full working knowledge of the functions, organization, and major components of a particular building
- Illustrations, plans, diagrams, schematics, and tables of every conceivable variety—each reflecting the latest ideas and practices, and each clearly rendered to help you design more functional, more meaningful, and more interesting buildings

This Second Edition is as complete and up to date as modern research methods will allow. Among the new building types included in this expanded edition are parking garages, fire stations, police stations, research laboratories, heliports, housing for the aged, housing for the handicapped, and nature centres.

This invaluable guide is an outgrowth and extension of the famed *Time-Saver Standards*, which for years has been the primary handbook of design data. Emphasis is on the basic planning and functional considerations for each type of building—and the same practical features that have kept the original work in demand through five editions have again been strictly adhered to.

Time-Saver Standards for Building Types will serve the needs of a broad range of professionals. For example...

- You're an architect commissioned to design a building of a type with which you're not familiar. *This single volume will save you valuable hours of research time and enable you to prepare knowledgeable preliminary plans.*
- You're a city planner interested in allocating funds for different uses and types of buildings. *From the reference material in this book, you can find all the information and data required to complete the task.*
- You're a member of a building committee that wants to construct a church or a school. *With this massively illustrated book you can help prepare a preliminary overall program, making effective decisions all along the way.*

Consulting engineers, interior designers, students, and all groups involved in developing and planning will find this book an invaluable aid in meeting their needs—from preliminary concepts right through to detailed designs.

Virtually all the essential data you need in conceiving, planning, programming, or designing any major type of building is set forth for you here. *No other book offers this kind of comprehensive, authoritative information and design data on the entire range of building types.*

ABOUT THE EDITORS

Joseph De Chiara is presently engaged in private practice as an architect and city planner in New York City. He has taught at Columbia, Pratt Institute, Cooper Union, the New York Institute of Technology, and the State University of New York (Farmingdale). He is the coauthor (with Lee K. Koppelman) of *Site Planning Standards* and author of the forthcoming *Handbook of Architectural Details for Commercial Buildings* (both McGraw-Hill). Mr. De Chiara received a Bachelor of Architecture degree from Pratt Institute and an M.S. in city planning from Columbia University.

John Hancock Callender was a professor of architecture at Pratt Institute and is now retired. He has been involved in research on new materials and methods of construction since 1932, including such subjects as industrial construction, curtain wall construction, arctic shelters, low-cost housing, and school construction. He has also taught at Columbia and directed research at Princeton. Prof. Callender is the Editor-in-Chief of *Time-Saver Standards for Architectural Design Data* (McGraw-Hill), now in its fifth edition.
